brake hardware kits. These kits usually include the items listed below for two drum brakes (axle set):

1. Primary and secondary return springs
2. Connecting spring
3. Hold-down springs
4. Hold-down spring retainers
5. Hold-down spring pins (nails)

TECH TIP

Time—Not Mileage—Is Important

Many brake experts recommend rebuilding or replacing wheel cylinders at every other brake job. Some experts recommend that the wheel cylinders be overhauled or replaced every time the brake linings are replaced. If the wheel cylinders are found to be leaking, they must be replaced or overhauled. The most important factor is time, not mileage, when determining when to repair or replace hydraulic components.

The longer the time, the more moisture is absorbed by the brake fluid. The greater the amount of moisture absorbed by the brake fluid, the greater the corrosion to metal hydraulic components. For example, the brakes will probably wear out much sooner on a vehicle that is used all day every day than on a vehicle driven only a short distance every week. In this example, the high-mileage vehicle may need replacement brake linings every year, whereas the short-distance vehicle will require several years before replacement brakes are needed. The service technician should try to determine the amount of time the brake fluid has been in the vehicle. The longer the brake fluid has been in the system, the greater the chances that the wheel cylinders need to be replaced or overhauled.

Self-adjuster kits are available in left- and right-handed threads for the left and right side of the vehicle. Other brake parts such as adjusters are available separately or as part of a self-adjuster kit. ● **SEE FIGURE 99–17**.

INSPECTING AND REPLACING BRAKE SHOES Carefully inspect the replacement brake shoes. Check all of the following:

1. Check that the replacements are exactly the same size (width and diameter) as the original. Hold the replacement shoes up against the old shoes to make the comparison.
2. Check for sound rivets (if rivet type). The friction material should also be snug against the metal brake shoe backing.

After checking that the replacement brake lining is okay, place the old shoes into the new linings' box. This helps ensure proper credit for the old shoes (called the core) as well as protection against asbestos contamination exposure.

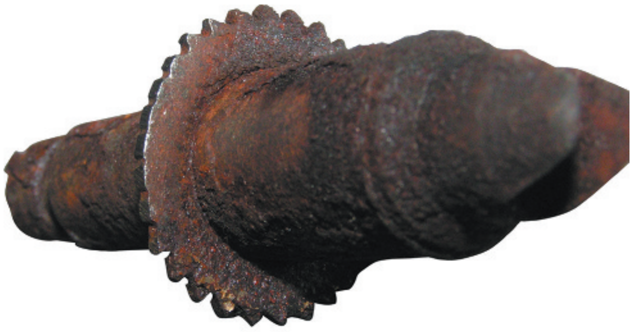

FIGURE 99–17 This starwheel adjuster is damaged and must be replaced. A lack of proper lubrication can cause the starwheel to become frozen in one place and not adjust properly.

BRAKE PARTS CLEANING Whenever cleaning brake parts or components, always use the following guidelines:

- Denatured alcohol or "brake clean" should only be used to clean brake parts that are disassembled. When individual parts are cleaned, they should be allowed to dry before being assembled.
- Never clean or flush assembled brake components with denatured alcohol or brake clean. Often, the alcohol cannot evaporate entirely from an assembled component. The trapped alcohol will evaporate inside the brake system, causing contamination. The trapped alcohol vapors also act like trapped air in the braking system and can cause a spongy brake pedal.
- Always clean assembled brake components with brake fluid.

LUBRICATION CHECKLIST For proper operation, the following points should be lubricated with approved brake lubricant:

1. The starwheel adjuster threads and under end caps
2. The backing plate contact areas (pads or ledges)
3. Anchor pins

CAUTION: Do not use wheel bearing or chassis grease on a braking system. Use only approved brake lubricant such as molybdenum disulfide (moly) grease, synthetic grease, lithium-based brake grease, or antiseize compound.

Also, be sure to check and lubricate the parking brake cable, if necessary.

REASSEMBLING THE DRUM BRAKE Reassembling the drum brake includes the following steps:

STEP 1 Carefully clean the backing plate.

STEP 2 Check the anchor pin for looseness.

STEP 3 Lubricate the shoe contact surfaces (shoe pads) with antiseize, brake grease, or synthetic grease.

STEP 4 Reassemble the primary and secondary shoes and brake strut, along with all springs.

STEP 5 Finish assembling the drum brake, being careful to note the correct location of all springs and parts.

NOTE: Many technicians preassemble the primary and secondary shoes with the connecting (lower retracting) spring as a unit before installing them onto the backing plate. ● SEE FIGURES 99–18 AND 99–19.

Most self-adjusters operate off the rear (secondary) shoe and should therefore be assembled toward the rear of the vehicle. Be sure that the star wheel adjuster is used on the correct side of the vehicle as the threads are different. ● **SEE FIGURE 99–20**.

ADJUSTING DRUM BRAKES

Most drum brakes are adjusted by rotating a starwheel or rotary adjuster. As the adjuster is moved, the brake shoes move toward the drum. If the brakes have been assembled correctly and with the parking brake fully released, both brake shoes should make contact with the anchor pin at the top. ● **SEE FIGURE 99–21** for an example where one shoe does not make contact with the anchor pin.

If the clearance between the brake shoes and the brake drum is excessive, a low brake pedal results. The wheel cylinder travel may

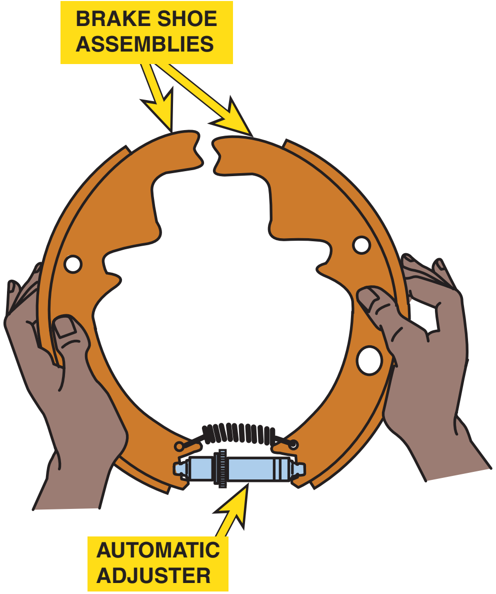

FIGURE 99–18 Pre-assembly of the starwheel adjuster with its connecting spring often helps when reassembling a drum brake. Check to make sure that the starwheel adjuster is on the correct side of the vehicle because they use different threads (left-hand and right-hand).

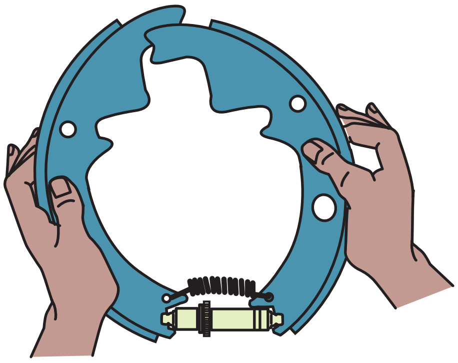

FIGURE 99–19 Sometimes it is necessary to cross the shoes when pre-assembling the starwheel adjuster and connecting spring.

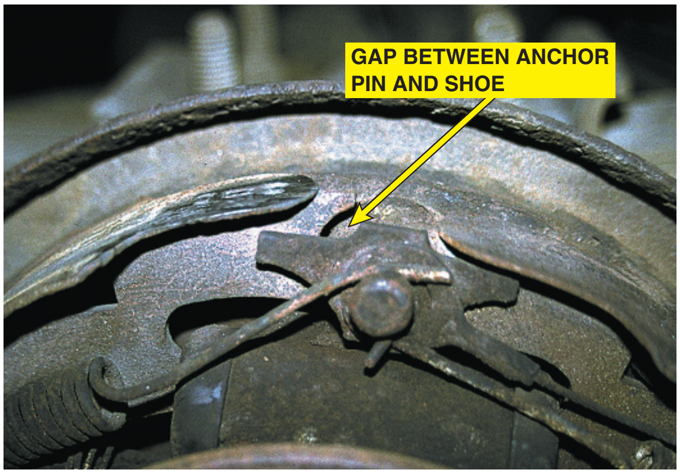

FIGURE 99–21 Notice that the brake shoe is not contacting the anchor pin. This often occurs when the parking brake cable is stuck or not adjusted properly.

not be adequate to cause the lining to contact the drums. Often, the driver has to pump the brakes to force enough brake fluid into the wheel cylinder to move it enough for braking action to occur.

Many technicians use a brake shoe clearance gauge to adjust the brake shoes before installing the drum. ● **SEE FIGURES 99–22 AND 99–23**.

CAUTION: Before installing the brake drum, be sure to clean any grease off the brake lining. Some experts warn not to use sandpaper on the lining to remove grease. The sandpaper may release asbestos fiber into the air. Grease on the linings can cause the brakes to grab.

TECH TIP

The Masking Tape Trick

Some technicians cover the friction material with masking tape to prevent contaminating the linings with dirt or grease during installation. After everything has been installed and double-checked, the masking tape is removed and the brake drums are installed. ● **SEE FIGURE 99–24**.

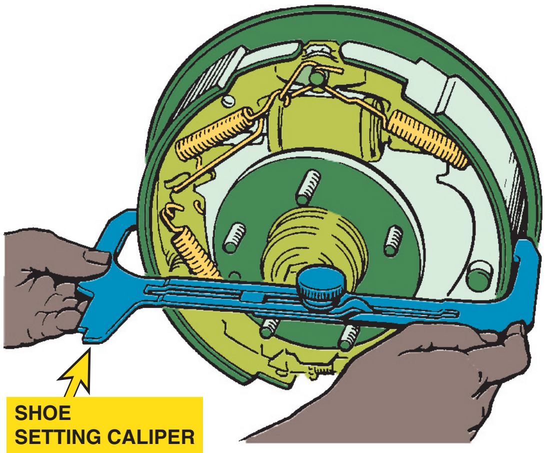

FIGURE 99–23 Place the gauge over the shoes and adjust the brakes until they contact the inside of the gauge.

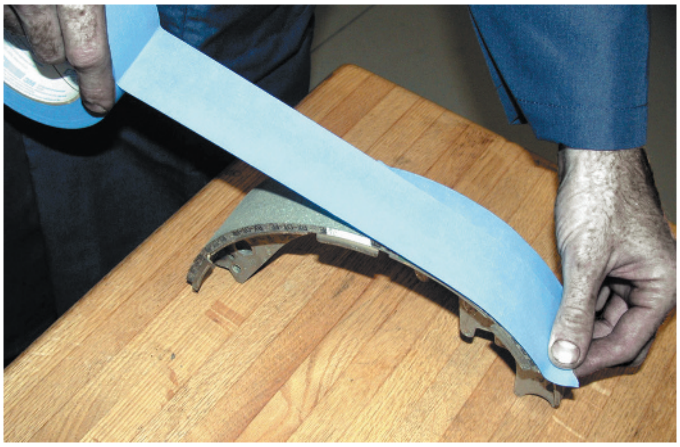

FIGURE 99–24 To prevent getting grease on the lining, the wise service technician covers the friction material with masking tape. The tape is removed after the brake shoes have been installed.

DRUM BRAKE FAULT SYMPTOM GUIDE

LOW PEDAL OR THE PEDAL GOES TO THE FLOOR Possible causes for low pedal include the following:

1. Excessive clearance between the linings and drum
2. Automatic adjusters not working
3. Leaking wheel cylinder
4. Air in the system

SPRINGY, SPONGY PEDAL Possible causes for springy, spongy pedal include the following:

1. Drums worn below specifications
2. Air in the system

EXCESSIVE PEDAL PRESSURE REQUIRED TO STOP THE VEHICLE Possible causes for excessive pedal pressure include the following:

1. Grease or fluid-soaked linings
2. Frozen wheel cylinder pistons
3. Linings installed on wrong shoes

LIGHT PEDAL PRESSURE—BRAKES TOO SENSITIVE Possible causes for light pedal pressure include the following:

1. Brake adjustment not correct
2. Loose backing plate
3. Lining loose on the shoe
4. Excessive dust and dirt in the drums
5. Scored, bell-mouthed, or barrel-shaped drum
6. Improper lining contact pattern

BRAKE PEDAL TRAVEL DECREASING Possible causes for brake pedal travel decreasing include the following:

1. Weak shoe retracting springs
2. Wheel cylinder pistons sticking

PULSATING BRAKE PEDAL (PARKING BRAKE APPLY PULSATES ALSO) Possible cause for pulsating brake pedal include the following:

1. Drums out-of-round

BRAKES FADE (TEMPORARY LOSS OF BRAKE EFFECTIVENESS WHEN HOT) Possible causes for brake fade include the following:

1. Poor lining contact
2. Drums worn below the discard dimension
3. Charred or glazed linings

SHOE CLICK NOISE Possible causes for shoe click noise include the following:

1. Shoes lift off the backing plate and snap back
2. Hold-down springs weak
3. Shoe bent
4. Grooves in the backing plate pads

THUMPING NOISE WHEN BRAKES ARE APPLIED Possible causes for thumping noise include the following:

1. Cracked drum; hard spots in the drum
2. Retractor springs unequal—weak

GRINDING NOISE Possible causes for grinding noise include the following:

1. Shoe hits the drum
2. Bent shoe web
3. Brake improperly assembled

ONE WHEEL DRAGS Possible causes for one wheel dragging include the following:

1. Weak or broken shoe retracting springs
2. Brake-shoe-to-drum clearance too tight—brake shoes not adjusted properly
3. Brake assembled improperly
4. Wheel cylinder piston cups swollen and distorted
5. Pistons sticking in the wheel cylinder
6. Drum out-of-round
7. Loose anchor pin/plate
8. Parking brake cable not free
9. Parking brake not adjusted properly

WET WEATHER: BRAKES GRAB OR WILL NOT HOLD Possible causes for brakes grabbing or not holding include the following:

1. Bent backing plate flange
2. Incorrect or abused shoe and linings

BRAKES SQUEAK Possible causes for brakes squeaking include the following:

1. Backing plate is bent or shoes twisted
2. Shoes scraping on backing plate pads
3. Weak or broken hold-down springs
4. Loose backing plate, anchor, or wheel cylinder
5. Glazed linings
6. Dry shoe pads and hold-down pin surfaces

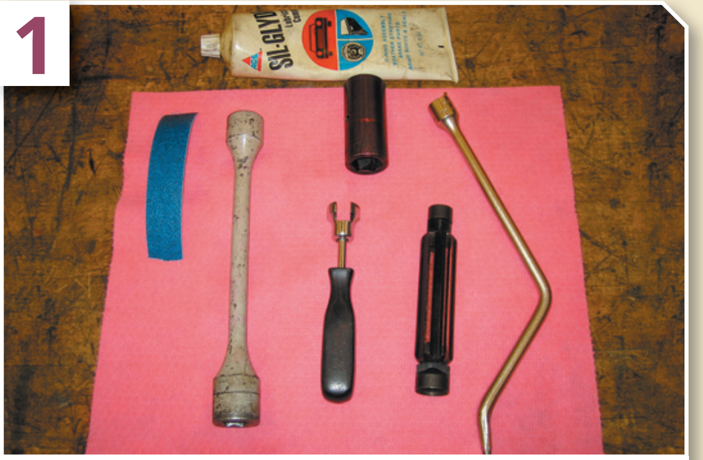
BRAKES CHATTER Possible causes for brake chattering include the following:

1. Incorrect lining-to-drum clearance
2. Loose backing plate
3. Weak or broken retractor spring
4. Drums out-of-round
5. Tapered or barrel-shaped drums
6. Improper lining contact pattern

DRUM BRAKE SERVICE

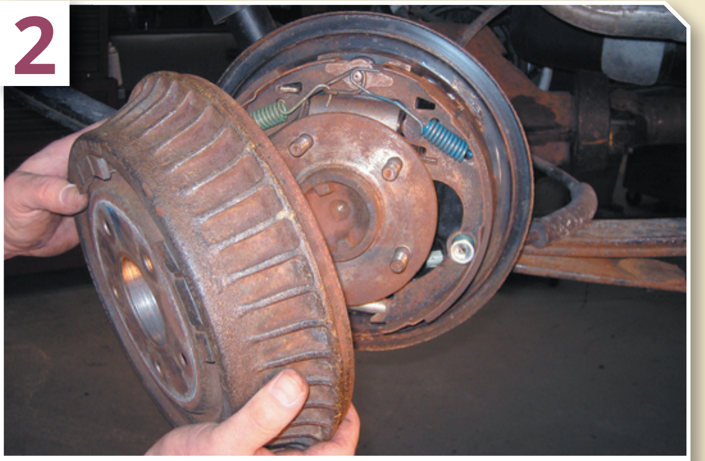
STEP BY STEP

1



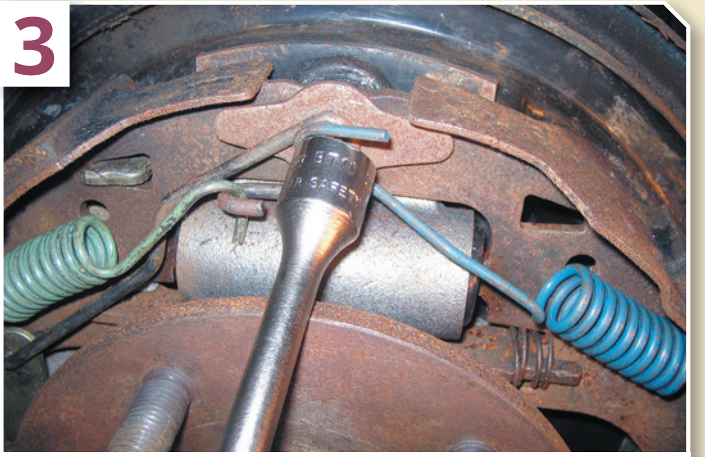
Tools needed to service a drum brake assembly include brake tools, silicone grease, lug nut wrench (socket).

2



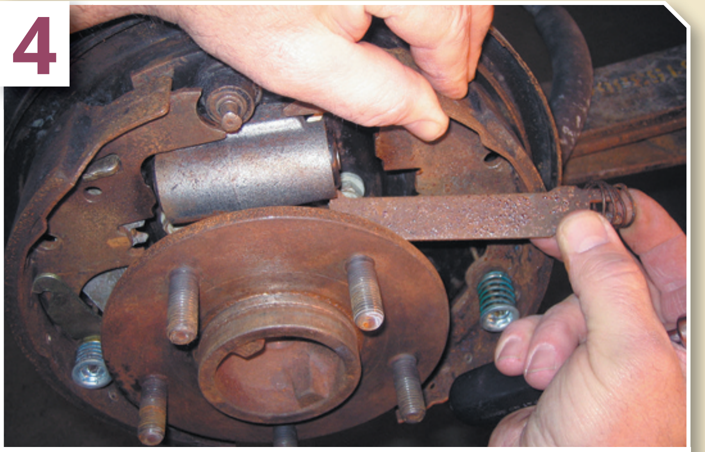
After safely hoisting the vehicle to chest height, remove the brake drum.

3



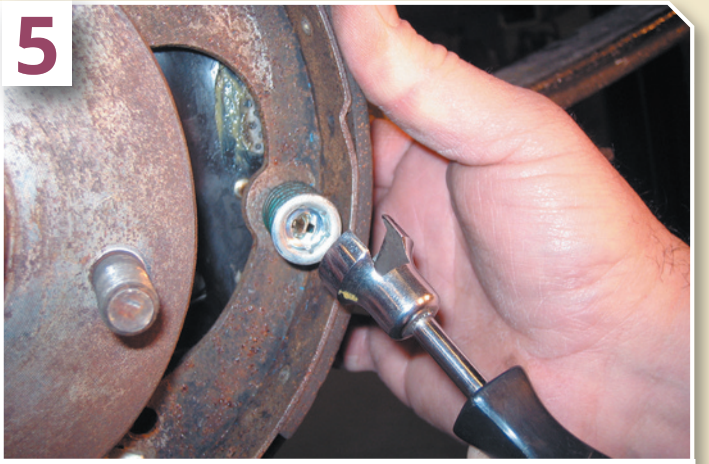
Remove the primary (forward facing) shoe return spring, using a brake tool. Then, remove the secondary return spring.

4



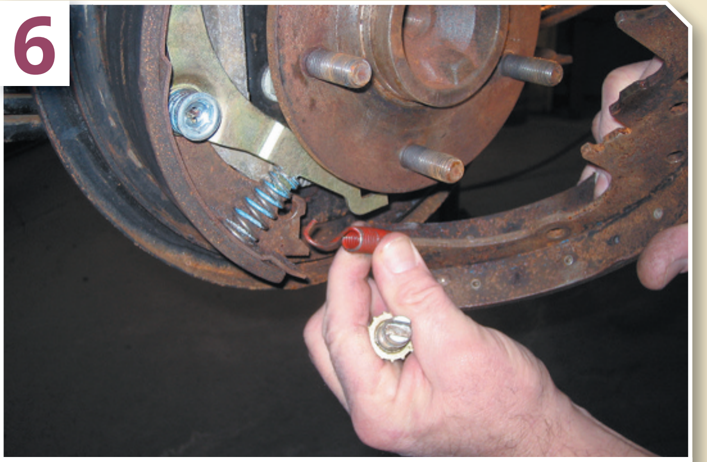
Remove the parking brake strut along with the antirattle spring.

5



Use a brake tool to depress the hold-down spring, and then rotate it until the slot in the retainer lines up with the flattened part of the hold-down pin.

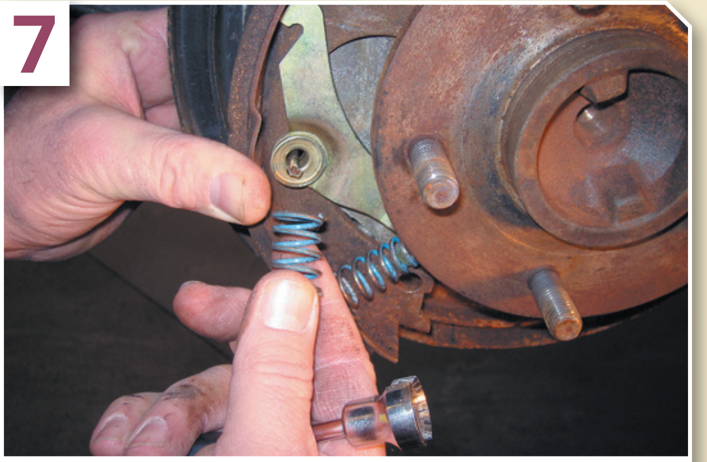
6



Removing the primary brake shoe plus the starwheel adjuster and connecting spring.

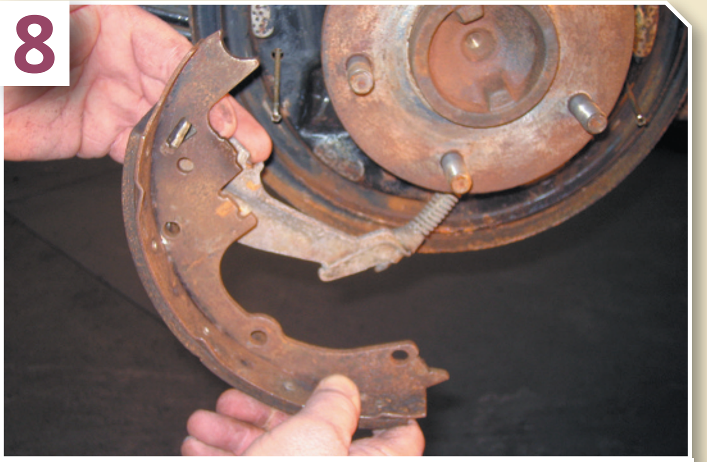
DRUM BRAKE SERVICE

7



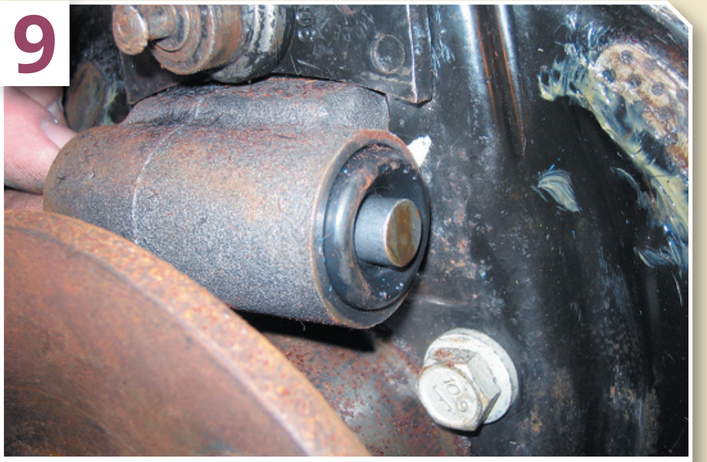
When the secondary lining hold-down spring is removed, the adjusting lever and pawl return spring can be removed.

8



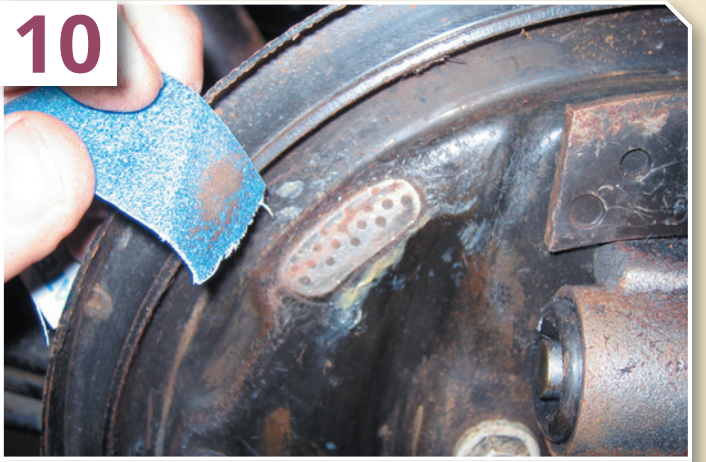
The parking brake lever can now be disconnected from the secondary brake shoe.

9



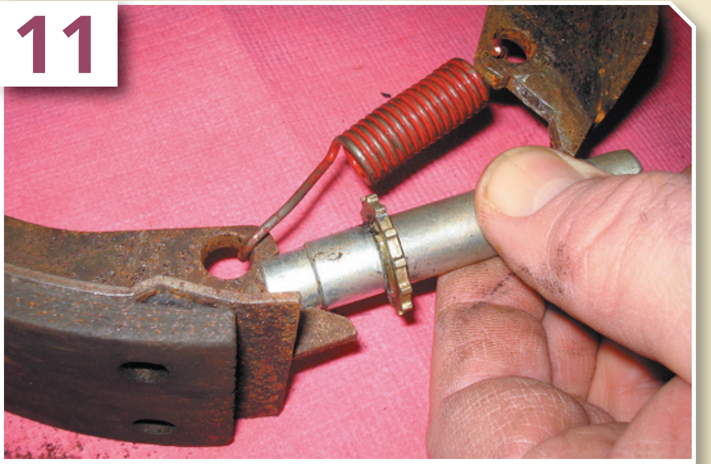
Check the wheel cylinder for leakage. This wheel cylinder is relatively new and not leaking.

10



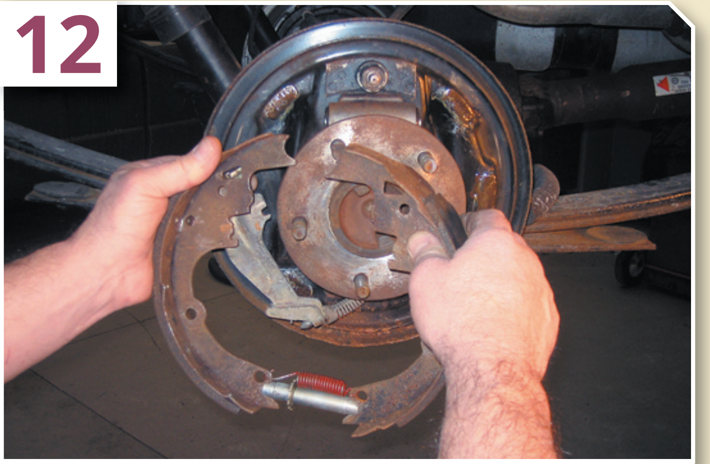
Clean all six brake shoe ledges. Lubricate the ledges with silicone brake grease.

11



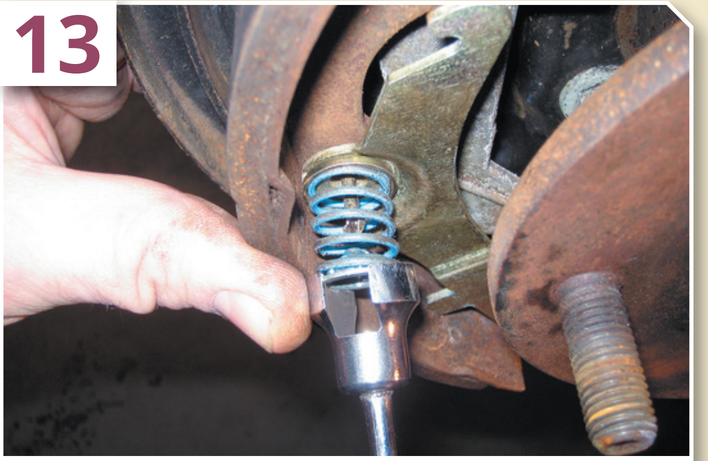
Many technicians prefer to assemble the connecting spring and starwheel adjuster to both shoes to help in the reinstallation.

12



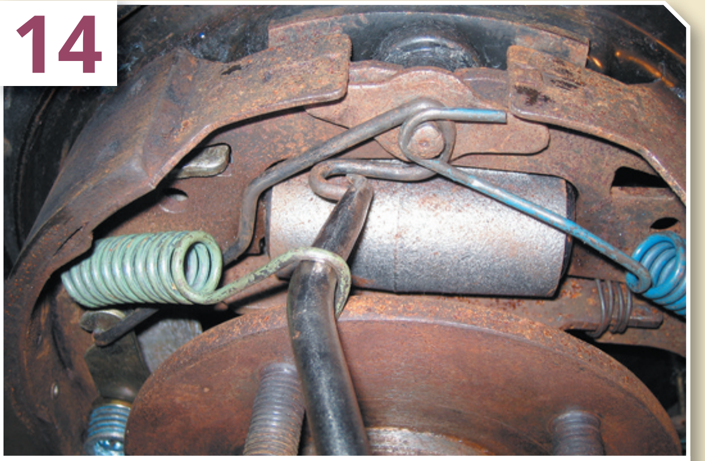
Attaching the parking brake lines to the secondary shoe. The assembled parts at the bottom help keep everything together.

13



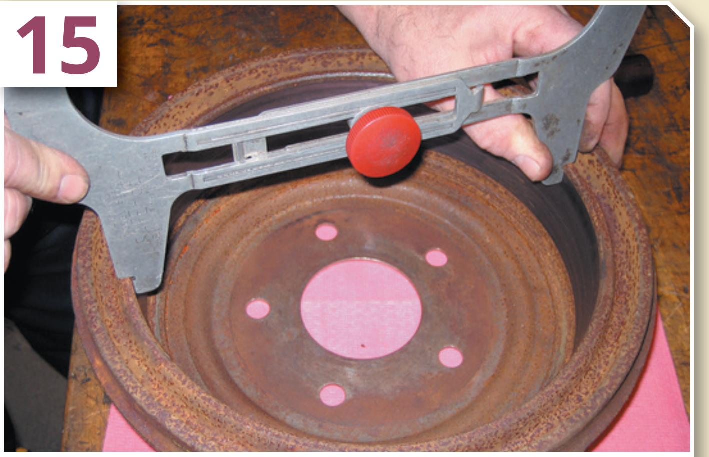
Installing the secondary shoe hold-down spring.

14



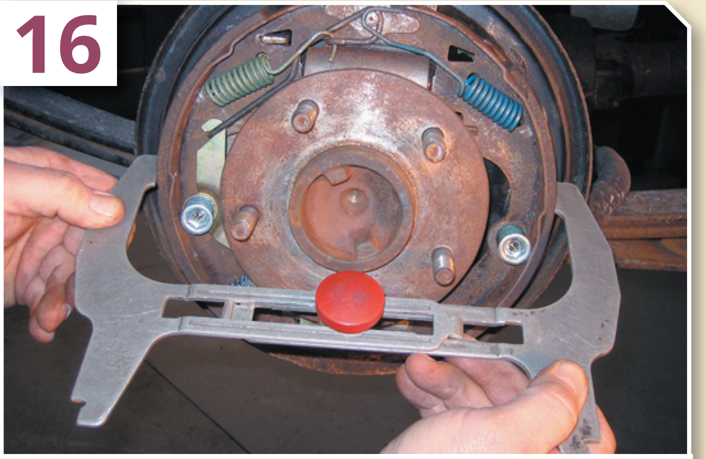
Installing the secondary shoe return spring. Note that the primary return spring has already been installed.

15



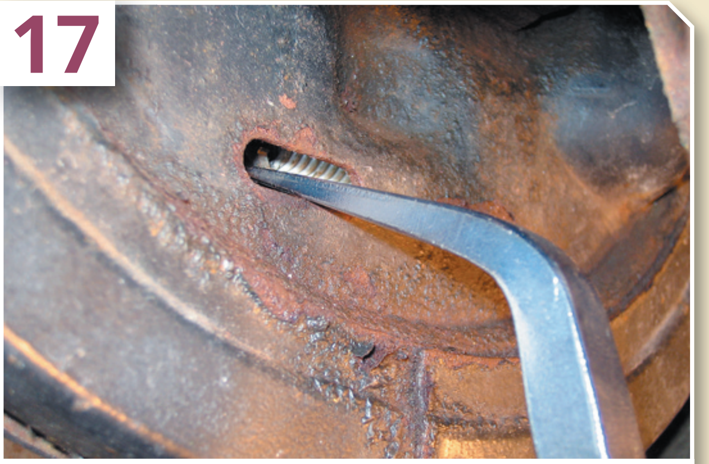
After installing the brake shoes and springs, use a drum/shoe clearance gauge and set it to the inside diameter of the drum.

16



Adjust the starwheel adjuster until the linings contact the drum brake shoe clearance gauge.

17



After installing the drum, it may be necessary to make the final adjustment using a brake adjusting tool (spoon).

18

After completing the brake service, be sure to cover the brake adjustment opening to prevent water from getting into the brake.

REVIEW QUESTIONS

1. Explain how to remove a brake drum.
2. List all items that should be lubricated on a drum brake.
3. List the steps necessary to follow when replacing drum brake linings.
4. Explain why many vehicle manufacturers do not recommend the wheel cylinder be honed.
5. What is the purpose of tinnerman nuts?

CHAPTER QUIZ

1. Technician A says that the tinnerman nuts are used to hold the brake drum on and should be reinstalled when the drum is replaced. Technician B says that a drum should be removed inside a sealed vacuum enclosure or washed with water or solvent to prevent possible asbestos dust from being released into the air. Which technician is correct?

DISC BRAKES

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Describe the parts and operation of disc brakes.
- Describe the construction of disc brakes.
- Discuss brake pads.
- Explain the different types of disc brake designs.
- Describe rear disc parking brakes.

KEY TERMS:

DISC BRAKES

PARTS AND OPERATION Disc brakes use a piston(s) to squeeze friction material (pads) on both sides of a rotating disc (rotor). Disc may be spelled *disk* by some manufacturers, but *disc* is the SAE (Society of Automotive Engineers) term and the most commonly used spelling in the industry. The rotor is attached to and stops the wheel.

Disc brakes are used on the front wheels of late-model vehicles, and on the rear wheels of an increasing number of automobiles. Disc brakes were adopted primarily because they can supply greater stopping power than drum brakes with less likelihood of fade. This makes disc brakes especially well-suited for use as front brakes, which must provide 60% to 80% of the vehicle's total stopping power.

DISC BRAKE ADVANTAGES Although increased federal brake performance standards hastened the switch to disc brakes, the front drum brakes would eventually have been eliminated anyway because disc brakes are superior in almost every respect. The disc brake friction assembly has several significant strong points, and only a few relatively minor weak points. ● **SEE FIGURE 100–1**.

The main advantages of the disc brake include the following:

FADE RESISTANCE The main design feature that helps disc brakes avoid heat-induced fade is their cooling ability because all of the major parts of a disc brake are exposed to the air flowing over the friction assembly. Many brake rotors also have cooling passages cast into them to further reduce operating temperatures and have greater fade resistance than drum brakes because they have greater swept area. **Swept area** is the amount of brake drum or rotor friction surface that moves past the brake linings every time the drum or rotor completes a rotation. Disc brakes are resistant to all kinds of fade, including the following:

- **Mechanical fade** is not a problem with disc brakes because, unlike a brake drum, the disc brake rotor expands *toward* the brake linings as it heats up rather than *away* from them. This fundamental design difference makes it physically impossible for heat to cause the rotor to expand out of contact with the brake linings. Because of this, there is never the need to move the brake linings out to keep them in contact with the rotor, so brake pedal travel does not increase. If the brake pedal on a vehicle with disc brakes drops toward the floor, it is almost always a sign of vapor lock, a fluid leak, fluid bypassing the seals in the master cylinder, or mechanical fade of the rear *drum* brakes.

- **Lining fade** can and does occur if the brakes become overheated. A little bit of heat brings the brake pads to their operating temperature and actually increases the friction coefficient of the lining material. A warm brake performs better than a cold brake. However, when too much heat is generated by braking, the lining material overheats. Its friction coefficient drops, and lining fade occurs.

  The primary symptom of lining fade is a hard brake pedal that requires the driver to apply greater force to maintain stopping power. Unlike the similar situation in a drum brake, however, increased application force will not distort the brake rotor because the caliper applies equal force to both sides. ● **SEE FIGURE 100–2**.

  Increased pressure will, however, create even more heat, and if brake lining temperatures continue to increase, gas fade and vapor lock of the hydraulic system can occur. If the pads are overheated to the point where the lining material is physically damaged, the brakes will not recover their full stopping power until the pads are replaced. ● **SEE FIGURE 100–3**.
- **Gas fade** is a problem only under severe braking conditions when hot gases and dust particles from the linings are trapped between the brake linings and rotor, where they act as lubricants. The symptoms of gas fade are the same as those for lining fade. The pedal becomes hard and increased force is required to maintain stopping power.

  Even though disc brakes operate at higher temperatures than drum brakes, they have fewer problems with gas fade for a number of reasons.

  1. Disc brakes do not have a drum to contain gases and particles in the area around the brake linings.

FIGURE 100–2 Braking force is applied equally to both sides of the brake rotor.

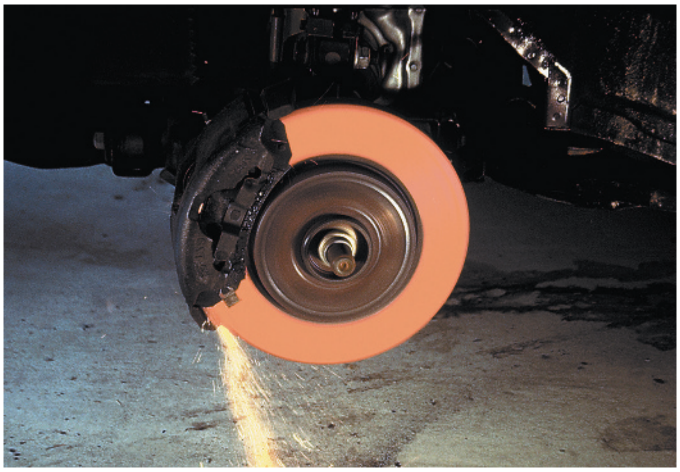

FIGURE 100–3 Disc brakes can absorb and dissipate a great deal of heat. During this demonstration, the brakes were gently applied as the engine drove the front wheels until the rotor became cherry red. During normal braking, the rotor temperature can exceed 350°F (180°C), and about 1,500°F (800°C) on a race vehicle.

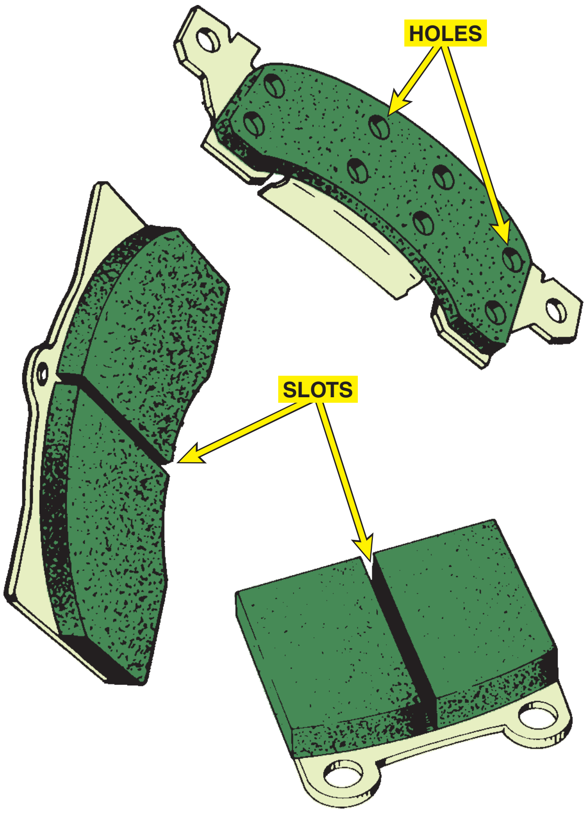

FIGURE 100–4 Slots and holes in the brake linings help prevent gas and water fade.

2. The constant flow of air over the brake carries away contaminants that might otherwise build up.
3. The surface area of the brake lining material in a disc brake is smaller than that of a comparable drum brake and this allows gases and particles to escape more easily.

To help prevent gas fade, many brake pads have slots cut in the lining material. These slots allow gases and dust particles to escape. ● **SEE FIGURE 100–4**. The holes required in riveted linings also perform this function. For even greater protection against gas fade, high-performance vehicles and motorcycles sometimes have holes or slots cut into the rotor. These openings allow gases and water to escape, and their sharp edges continually wipe loose particles off the linings.

- **Water fade** is not a big problem with disc brakes because centrifugal force created by the spinning rotor throws off most moisture, and the brake pads positioned only a few thousandths of an inch away from the rotor continuously wipe it clean. When the brakes are applied, the leading edge of the brake pad lining material wipes the last bit of water from the disc. Once good lining-to-rotor contact is established, water is unable to enter the space between the linings and rotor until the brakes are released.

Although far more resistant to water fade than drum brakes, disc brakes are not entirely free from its effects. Splash shields and the vehicle's wheels help keep water off of the rotor, and the brake lining materials specified for most vehicles minimize the effects of water fade.

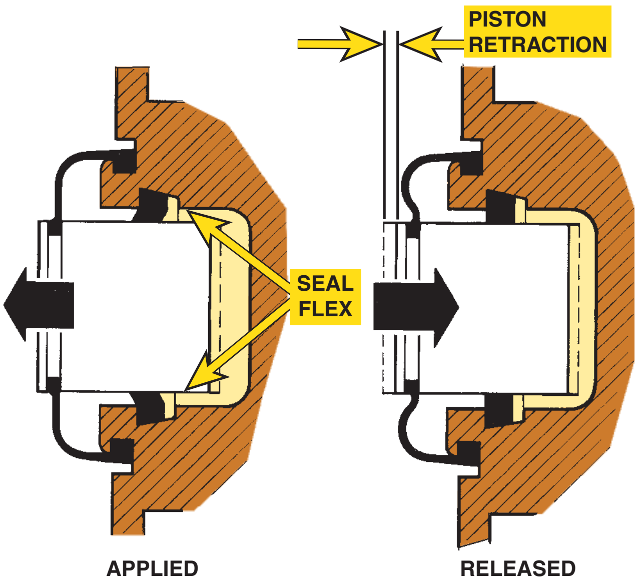

FIGURE 100–5 The square-cut O-ring not only seals hydraulic brake fluid but also retracts the caliper piston when the brake pedal is released.

SELF-ADJUSTING ABILITY Disc brakes are self-adjusting because any wear of the linings is automatically compensated for by the action of the brake caliper.

When the brakes are applied, the caliper pistons move out as far as needed to force the brake pads into contact with the rotor. When the brakes are released, the piston retracts only the small distance dictated by rotor runout and piston seal flex. ● **SEE FIGURE 100–5**. The surface finish on the piston must be clean to allow the piston to slide past this seal. Excessive friction between the caliper piston and the caliper bore can prevent the piston from retracting. If the force of the caliper seal is not strong enough, the piston stays in the applied position. Because the brake pads are still in contact with the rotor, one or both pads will show excessive wear.

FREEDOM FROM PULL A disc brake will stop straighter under a wider range of conditions than will a drum brake. A disc brake is self-cleaning, will throw off most water, and is less likely to pull.

Disc brakes do not have self-energizing or servo action. Because disc brakes do not use friction between the linings and rotor to increase their braking power, the effects of a loss of friction on one side of the vehicle are far less pronounced than with drum brakes.

TECH TIP

Check the Tire Size for a Pulling Problem

If an unequal braking problem is being diagnosed, check that the front tires match and that the rear tires match. Brakes slow and stop wheels. Unequal diameter tires create an unequal braking force. The result may be a pulling toward one side while braking. Tire diameter can vary from one tire manufacturer to another even though the size designation is the same. Even slight differences in the wear of tires can cause a different tire diameter and, therefore, a different braking force.

DISC BRAKE DISADVANTAGES The most notable fact about the disadvantages of disc brakes is that there are so few. The weaknesses of disc brakes include the following:

- **No self-energizing or servo action**—The disc brake's lack of self-energizing or servo action is a disadvantage for two reasons.
    1. It contributes to poor parking brake performance and requires the driver to push harder on the brake pedal for a given stop. However, the problem of high pedal pressures has been eliminated through the use of brake power boosters.
    2. It is easier to modulate the brakes for the exact amount of stopping power desired.
- **Brake noise**—Probably the biggest complaint about disc brakes is that they sometimes make various squeaks and squeals during a brake application. As long as the brake linings are not worn down to the backing plate, these noises are usually caused by high-frequency rattling or vibration of the brake pads. Several methods are used to quiet noisy disc brakes. Manufacturers use specific lining materials that damp vibrations, and most calipers have **antirattle clips** or springs that hold the pads in the caliper under tension to help prevent vibration. ● **SEE FIGURE 100–6**.

Some calipers use special shims between the brake pad backing plate and the caliper piston to damp vibrations. ● **SEE FIGURE 100–7**. These shims may be made of metal or fiber. Antinoise sprays and brush-on liquids are available and provide a cushion layer between the pad and the caliper piston. The bond lowers the **natural frequency** of the pad, and the cushion layer damps any vibration that may still occur.

BRAKE DUST Because the lining is exposed on a disc brake, rather than being enclosed as on a drum brake, some brake dust can accumulate on the wheels. This brake dust is often dark brown or black and can stain wheels if not cleaned often or protected from the dust.

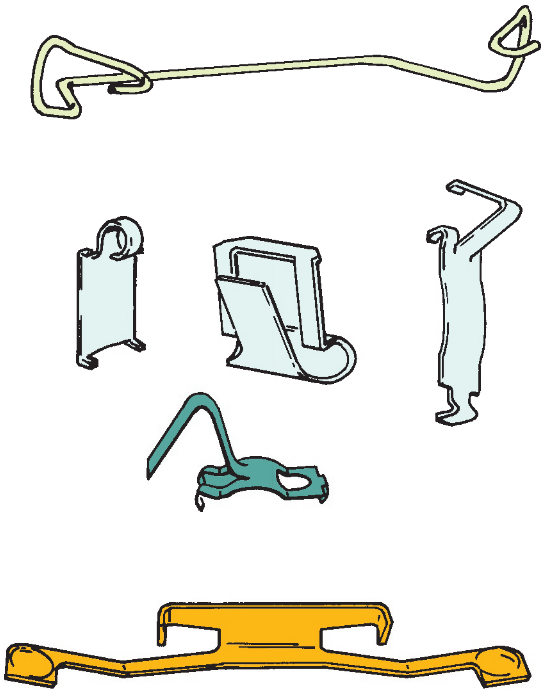

FIGURE 100–6 Antirattle clips reduce brake pad movement and vibration.

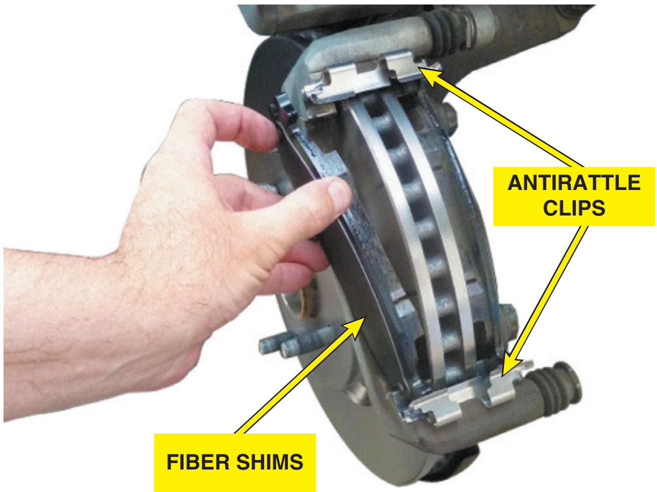

FIGURE 100–7 Antivibration shims are used behind the pads on many disc brake caliper designs.

TECH TIP

Wax the Wheels

Brake dust from semimetallic brake pads often discolors the front wheels. Customers often complain to service technicians about this problem, but it is normal for the front wheels to become dirty because the iron and other metallic and nonmetallic components wear off the front disc brake pads and adhere to the wheel covers. A coat of wax on the wheels or wheel covers helps prevent damage and makes it easier to wash off the brake dust.

POOR PARKING BRAKE PERFORMANCE The lack of self-energizing or servo action plays a large part in poor disc brake parking brake performance. The lining-to-rotor contact area of a disc brake is somewhat smaller than the lining-to-drum contact area of a drum brake. This causes the disc brake to have a lower static coefficient of friction, and therefore less holding power when the vehicle is stopped.

DISC BRAKE CONSTRUCTION

CALIPER With the exception of the rotor, the caliper is the largest part of a disc brake friction assembly. The brake caliper uses hydraulic pressure to create the mechanical force required to move the brake pads into contact with the brake rotor. At the front axle, the caliper mounts to the spindle or steering knuckle. ● **SEE FIGURE 100–8**. Rear disc brake calipers mount to a support bracket on the axle flange or suspension. ● **SEE FIGURE 100–9**.

DISC BRAKE ROTOR TYPES The brake rotor provides the friction surfaces for the brake pads to rub against. The rotor, the largest and heaviest part of a disc brake, is usually made of cast iron because that metal has excellent friction and wear properties. There are two basic types of rotors:

- **Solid**—Solid rotors are most often used on the rear of vehicles equipped with four-wheel disc brakes.
- **Vented**—Vented rotors have radial cooling passages cast between the friction surfaces. ● **SEE FIGURE 100–10**.

SPLASH SHIELD The splash shield bolts to the front spindle or steering knuckle, or in rear disc brake applications, to the axle flange or a suspension adapter plate. The job of the splash shield is to protect the inner side of the brake rotor from water and other contaminants, whereas the outer side of the rotor is protected by the wheel. Most splash shields are made of stamped steel or plastic.

DISC BRAKE PADS

DESIGN FEATURES The lining of a disc brake is part of an assembly called the **brake pad.** ● **SEE FIGURE 100–11**. Compared to a brake shoe, a brake pad is a relatively simple part that consists of a block of friction material attached to a stamped steel backing plate. Some pad backing plates have tabs that bend over the caliper to hold the pad tightly in place and help prevent brake noise. ● **SEE FIGURE 100–12**.

FREQUENTLY ASKED QUESTION

Why Are Some Brake Pads Slotted and Others Not?

Brake pads are designed by the vehicle manufacturer for each specific application. Some are tapered at the ends and others are slotted and many are tapered and slotted. According to brake design engineers, these features are designed to help reduce brake noise. By changing the size of the pad area or by breaking it up into sections by slotting, the frequency of the sound generated during braking changes. For best results, use a replacement brake pad that has the same design features as the original brake pads.

Other pad backing plates have tabs with holes in them as shown in ● **FIGURE 100–13**. A pin slips through the holes and fastens to the caliper body to hold the pads in position. Still other pad backing plates have a retainer spring attached that locates the pad in the caliper by locking it to the caliper piston. ● **SEE FIGURE 100–14**.

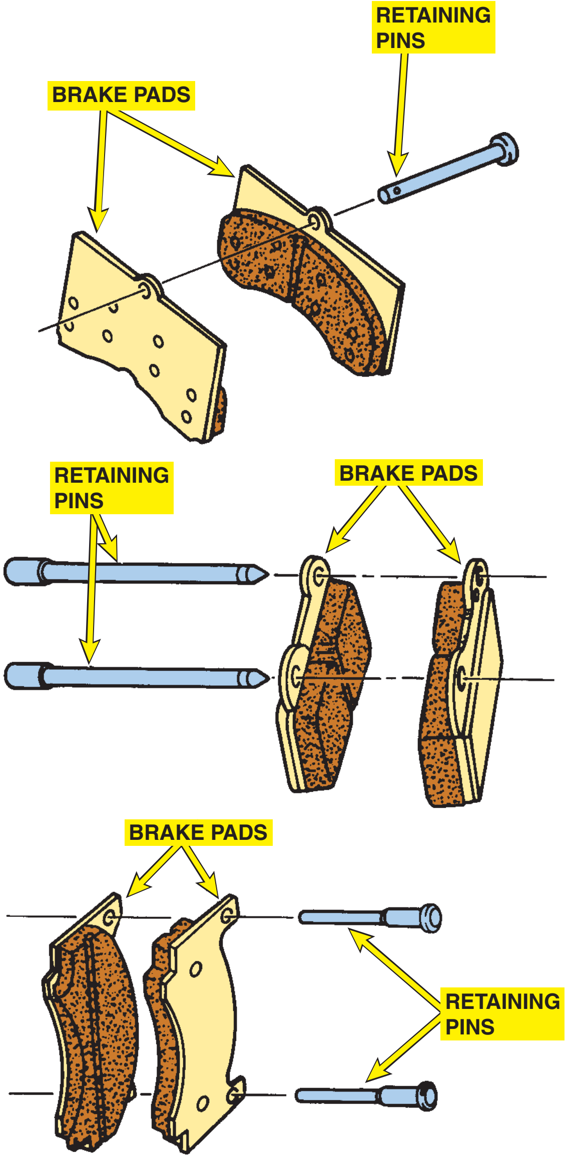

FIGURE 100–13 Holes in the backing plate are a method of locating a pad in the caliper.

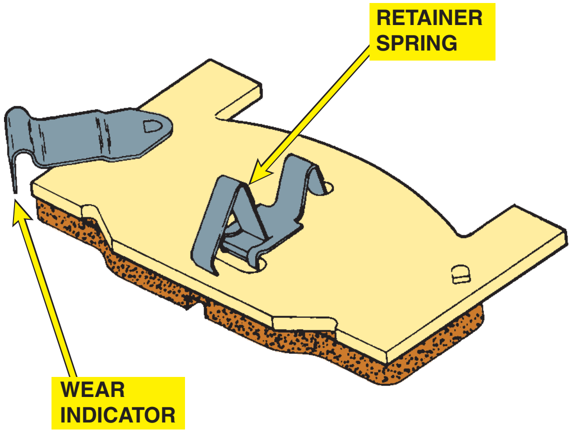

FIGURE 100–14 Retainer springs lock the pad to the caliper piston to prevent brake noise.

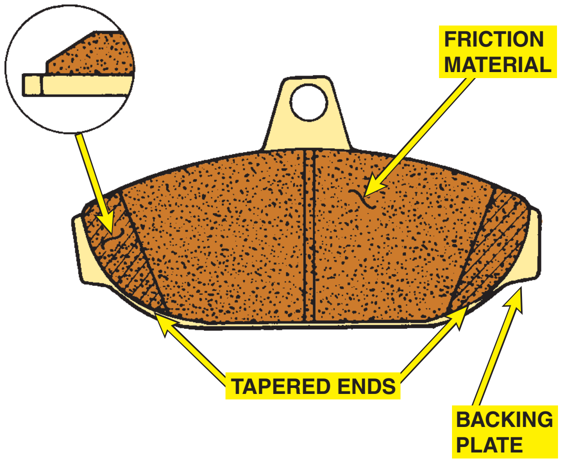

FIGURE 100–15 The lining edges of some brake pads are tapered to help prevent vibration.

As with brake shoes, the lining material of a disc pad can be any one of a number of products that can be fastened to the backing plate in several ways. The edges of the lining material on a brake pad are usually perpendicular to the rotor surface, although a few larger pads do have tapered edges to help combat vibration and noise. ● **SEE FIGURE 100–15**.

PAD WEAR INDICATORS Although not required by law, a growing number of vehicle manufacturers are fitting **pad wear indicators** to their brakes for safety reasons. Pad wear indicators are either mechanical or electrical and signal the driver when the lining material has worn to the point where pad replacement is necessary.

A mechanical wear indicator is a small spring-steel tab riveted to the pad backing plate. When the friction material wears to a predetermined thickness, the tab contacts the rotor and makes a squealing or chirping noise (when the brakes are not applied) that alerts the driver to the need for service. ● **SEE FIGURE 100–16**.

Electrical wear indicators, such as those shown in ● **FIGURE 100–17**, use a coated electrode embedded in the lining material to generate the warning signal. The electrode is wired to a warning light in the instrument panel and when the lining wears sufficiently, the electrode grounds against the rotor to complete the circuit and turn on the warning light.

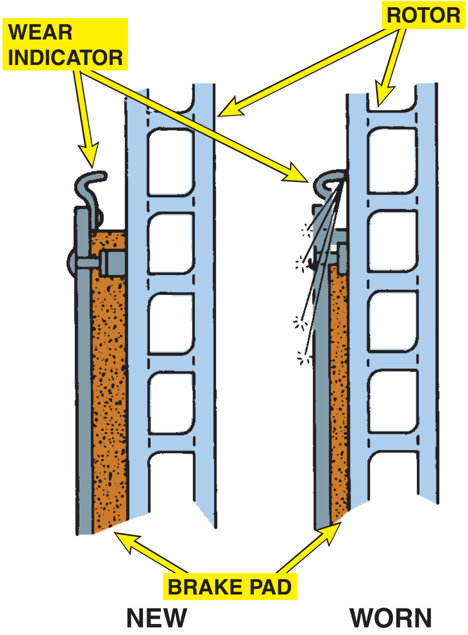

FIGURE 100–16 Typical pad wear sensor operation. It is very important that the disc brake pads are installed on the correct side of the vehicle to be assured that the wear sensor will make a noise when the pads are worn. If the pads with a sensor are installed on the opposite side of the vehicle, the sensor tab is turned so that the rotor touches it going the opposite direction. Usually the correct direction is where the rotor contacts the sensor before contacting the pads when the wheels are being rotated in the forward direction.

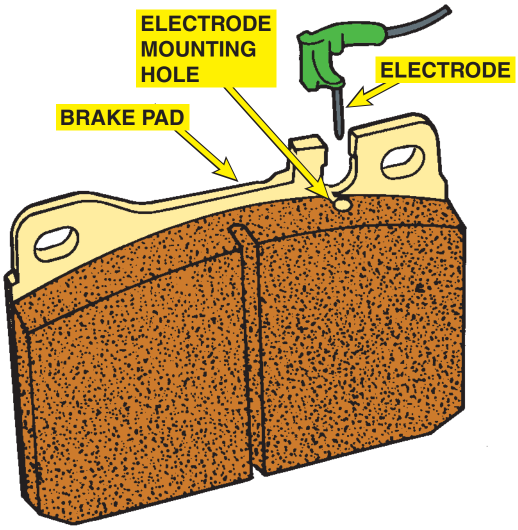

FIGURE 100–17 Electrical wear indicators ground a warning light circuit when the pads need replacement.

On newer vehicles, the pad wear sensor is a two wire input to the electronic brake control module (EBCM). The module can detect faults in the sensor wiring. When a pad sensor begins to ground out against the brake rotor, the EBCM uses the serial data link to display a warning message in the driver information center (DIC).

PAD ASSEMBLY METHODS As mentioned previously, there are several methods that are used to mount brake linings, including the following:

- **Riveted linings** take advantage of the oldest method of lining attachment still in use. In this system, the **brake block** is attached to the backing plate with copper or aluminum rivets.

  The major advantage of riveting is that it allows a small amount of flex between the brake block backing plate. This play enables the assembly to absorb vibration, and the result is that riveted linings operate more quietly than bonded linings. However, the rivet holes create stress points in the lining where cracks are likely to develop.
- **Bonded linings** use high-temperature adhesive to glue the brake block directly to the shoe pad backing plate. Heat and pressure are then applied to cure the assembly. Bonding is a common form of shoe and pad assembly, and is most often used to mount organic friction materials.

  Bonding offers several advantages. Without rivets, bonded linings can wear closer to the backing plate and provide a longer service life. If the linings wear too far, bonding adhesive is not as destructive to rotors as rivets. Bonded linings also have fewer problems with cracking because they have no rivet holes to weaken the brake block. The primary disadvantage of bonded linings is a limited ability to withstand high temperatures. If a bonded lining gets too hot, the bonding adhesive will fail and allow the brake block to separate from the backing plate. Bonded linings are also more prone to be noisy because they do not allow any vibration absorbing flex between the brake block and backing plate.
- **Mold-bonded linings** are found on some disc brake pads. Mold bonding is a manufacturing process that combines the advantages of bonding with some of the mechanical strength of riveting. Instead of riveting and/or bonding a cured brake block to a separate backing plate, the friction material in a mold-bonded pad is cured on the backing plate during manufacture. This process is also called **integrally molded.** Most high-performance disc brake pads are made in this way.

  To make a mold-bonded pad, one or more holes are punched in the pad backing plate, and a high-temperature adhesive is applied to it. The backing plate is then installed in a molding machine where uncured friction material is formed onto the plate and forced into the holes. ● **SEE FIGURE 100–18**. Once the pad is cured under heat and pressure, the bonding adhesive combines with the portions of the lining that extend into the backing plate holes to solidly lock the brake block in place.

DISC BRAKE DESIGNS

There are three types of calipers:

1. Fixed
2. Floating
3. Sliding

FIXED CALIPER DESIGN The **fixed brake caliper** is the earliest design. ● **SEE FIGURE 100–19**. The fixed caliper has a body manufactured in two halves, and uses two, four, or six pistons to apply the brake pads. The fixed caliper gets its name from the fact that the caliper is rigidly mounted to the suspension. When the brakes are applied, the pistons extend from the caliper bores and apply the brake pads with equal force from both sides of the rotor. No part of the caliper body moves when the brakes are applied.

FIXED CALIPER ADVANTAGES Fixed calipers are relatively large and heavy, which enables them to absorb and dissipate great amounts of heat. This allows the brake rotor and pads to run cooler, and reduce the amount of heat transferred to the brake fluid. Compared with other caliper designs, a fixed caliper is able to withstand a greater number of repeated hard stops without heat-induced fade or vapor lock of the hydraulic system.

The size and rigid mounting of a fixed caliper also means it does not flex as much as other designs. A caliper that is flexing is usually felt by the driver as a spongy brake pedal. Fixed calipers are very strong and provide a firm and linear brake pedal feel.

The strength and heat-dissipating abilities of fixed calipers make them best suited for heavy-duty use such as in most race vehicles.

FIXED CALIPER DISADVANTAGES The size and weight of fixed calipers are advantages in heavy-duty use, but they add weight to the vehicle.

Another disadvantage of fixed calipers is that with multiple pistons and split bodies, service is more difficult and allows greater opportunity for leaks. The drilled passages that route fluid through the inside of the caliper body also contribute to cracking as miles accumulate and the caliper goes through hundreds of thousands of heating and cooling cycles.

FLOATING AND SLIDING CALIPER DESIGN

The front brakes of most vehicles are fitted with either floating or sliding calipers, which are *not* rigidly mounted. The caliper is free to move within a limited range on an **anchor plate** that *is* solidly mounted to the vehicle suspension. The anchor plate may be cast into a suspension member (often the front spindle) or it can be a separate piece that bolts to the suspension. ● **SEE FIGURE 100–20**.

When the brakes are applied, the caliper piston moves out of its bore and applies the inner brake pad. At the same time, the caliper body moves in the opposite direction on the anchor plate and applies the outer brake pad. With a floating or sliding caliper, the caliper body moves every time the brakes are applied. ● **SEE FIGURE 100–21**.

NORMAL CALIPER OPERATION The piston moves just enough to distort the caliper seal and returns to the original position when the brake pedal is released.

WEAR COMPENSATION The piston moves more than the caliper seal can distort. It moves through the seal until the pad contacts the rotor. The caliper piston returns to the released position by the seal distortion, the same as during normal operation, except now in a different, more applied position.

As the wear occurs and the piston moves, additional brake fluid is needed behind the piston. This additional brake fluid comes from the master cylinder and the brake fluid level drops as the disc brake pads wear.

FLOATING AND SLIDING CALIPER ADVANTAGES The biggest advantages of floating and sliding calipers are lower cost, simple construction, and compact size. Most floating and sliding calipers are single-piston designs. Because they have fewer pieces, floating and sliding calipers are cheaper to build and service, and have fewer places where leaks can develop.

The smaller size of floating and sliding calipers also allows better packaging of the caliper on the vehicle. A single-piston caliper with the piston located on the inboard side of the brake rotor fits easily within the diameter of a small wheel. The inboard position of the caliper piston also contributes to better cooling because the bulk of the caliper body is exposed to the passing airflow.

Like any disc brake, floating and sliding calipers have poor parking brake performance. Unlike a fixed caliper, a floating or sliding caliper can be mechanically actuated by applying the single piston with a cable and lever mechanism.

FLOATING AND SLIDING CALIPER DISADVANTAGES The movable caliper body allows a certain degree of flex, which can contribute to a spongy brake pedal. Caliper flex also allows the caliper body to twist slightly when the brakes are applied, causing tapered wear of the brake pad lining material. ● **SEE FIGURE 100–22**.

Although the inboard piston location of floating and sliding calipers provides good cooling, these designs can never absorb as much heat (and therefore have the fade resistance) as a fixed caliper with similar stopping power. Floating and sliding calipers simply do not have the mass of fixed calipers, and their flexible mounting systems slow the transfer of heat from the caliper body to the anchor plate and other suspension components that aid in the cooling process.

FLOATING CALIPER OPERATION

The body of a **floating caliper** does not make direct metal-to-metal contact with the anchor plate. ● **SEE FIGURE 100–23**. Instead, the caliper body is supported by bushings and/or O-rings that allow it to "float" or slide on metal guide pins or locating sleeves attached to the anchor plate. For this reason, some automakers call the floating caliper a **pin-slider caliper.**

The bushings that support floating calipers are made from a number of materials including rubber, Teflon, and nylon. The O-rings are generally made from high-temperature synthetic rubber. ● **SEE FIGURE 100–24**. The guide pins and sleeves are

FIGURE 100–21 Hydraulic force on the piston (left) is applied to the inboard pad and the caliper housing itself. The reaction of the piston pushing against the rotor causes the entire caliper to move toward the inside of the vehicle (large arrow). Since the outboard pad is retained by the caliper, the reaction of the moving caliper applies the force of the outboard pad against the outboard surface of the rotor.

FREQUENTLY ASKED QUESTION

What Is a Low-Drag Caliper?

A **low-drag caliper** differs from a standard caliper in the area of the square-cut O-ring. A V-shaped cutout allows the O-ring to deflect more and, as a result, is able to pull the caliper piston back into the bore when the brakes are released. Because of this further movement, the brake pads are pulled farther from the rotor and are less likely to drag. The negative aspect of this design is that greater volume of brake fluid is needed to achieve a brake application. To compensate for this need for greater brake fluid volume, a quick-take-up master cylinder was designed and is used whenever low-drag calipers are used. ● **SEE FIGURE 100–26**.

made of steel and come in a variety of shapes and sizes for different caliper designs. ● **SEE FIGURE 100–25**.

Floating calipers depend on proper lubrication of their pins, sleeves, bushings, and O-rings for smooth operation. If these parts become rusted or corroded, the caliper will bind and stick, causing loss of braking power that is usually accompanied by rapid and unusual wear of brake pads. Special high-temperature brake grease must be used to lubricate these parts any time the caliper is disassembled. Many manufacturers recommend that floating caliper pins, sleeves, bushings, and O-rings be replaced whenever the caliper is serviced. These parts come in a "small parts kit" available from brake part suppliers.

FIGURE 100–26 In a standard disc brake caliper, the square-cut O-ring deforms when the brakes are applied and returns the piston to its original (released) position due to the elastic properties of the rubber seal. In a low-drag caliper design, the groove for the square-cut O-ring is V-shaped, allowing for more retraction. When the brake pedal is released, the piston is moved away from the rotor further, resulting in less friction between the disc brake pads and the rotor when the brakes are released.

SLIDING CALIPERS Unlike a floating caliper, the body of a **sliding caliper** mounts in direct metal-to-metal contact with the anchor plate. ● **SEE FIGURE 100–27**.

Instead of pins and bushings, sliding calipers move on **ways** cast and machined into the caliper body and anchor plate. ● **SEE FIGURE 100–28**. Retaining clips and the design of the caliper prevent the body from coming out of the ways once the caliper is assembled. On some calipers, the ways may have to be filed for proper clearance between the caliper body and anchor plate if the caliper is replaced.

Like floating calipers, sliding calipers depend on good lubrication of their ways for proper operation. If not properly coated with high-temperature brake grease, the ways can rust or corrode, causing the caliper to drag or seize.

REAR DISC BRAKES

REAR DISC PARKING BRAKES There are two methods of providing parking brakes when rear discs are installed on a vehicle.

1. Adapt the disc brake to also function as the parking brake. This is done by installing a series of cables, levers, and internal parts to mechanically actuate the brake caliper. ● **SEE FIGURES 13–29 AND 13–30**.
2. Use mechanically actuated drum brakes inside the rear rotors. ● **SEE FIGURE 100–31**.

DISC BRAKE DIAGNOSIS AND SERVICE

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Discuss how to diagnose problems with disc brakes.
- Explain visual inspection of disc brakes and pads.
- Describe disc brake caliper service.
- Describe caliper installation.
- Explain disc brake squeal correction.
- State the symptoms of a faulty disc brake.

KEY TERMS:

Abutments 1187 • Antiseize compound 1190 • Bedded-in 1189 • Burnished 1189 • Constrained layer shims (CLS) 1190 • Lithium-based brake grease 1190 • Loaded calipers 1187 • Molybdenum disulfide (MOS_2) grease 1190 • Polyalphaolefin (PAO) 1190 • Reaction pads 1187 • Silicone grease 1190 • Synthetic grease 1190 • Ways 1187

DISC BRAKE DIAGNOSTIC PROCEDURES

When diagnosing disc brake concerns, perform the following steps:

STEP 1 The first step is to verify the customer complaint. This step usually includes test-driving the vehicle to see if the complaint can be duplicated. If the problem cannot be duplicated, then the repair or service cannot be verified.

CAUTION: Do not test-drive the vehicle on public roads if the red brake warning light is on. Perform a visual inspection to determine the reason for the warning light being on and correct before test-driving the vehicle.

STEP 2 Check the brake pedal height and verify proper operation. If the brake pedal is low, check the parking brake and count the number of "clicks." There should be 3 to 7 clicks. If there are over 10 clicks, check the rear brakes.

STEP 3 Safely hoist the vehicle and remove the wheels. Visually check the following:

- Flexible brake lines for wear or damage
- Disc brake rotors for excessive rust or scoring
- Disc brake calipers for leakage or damage

STEP 4 Remove disc brake calipers and check the disc brake pads for proper lining thickness and check for cracks or other damage.

TECH TIP

Let the Owner Drive

When verifying the customer complaint, ask the owner or driver of the vehicle to drive. Often, the problem is best discovered if the vehicle is being driven exactly the same way as when the complaint first occurred. For example, the technician may brake harder or softer than the driver; so, the problem may not be detected.

STEP 5 Replace all components that do not meet factory specifications.

STEP 6 Test-drive the vehicle to verify that the repairs did correct the customer concern.

VISUAL INSPECTION

Even with operating wear-indicating sensors, a thorough visual inspection is very important. ● **SEE FIGURE 101–1**. A lining thickness check alone should not be the only inspection performed on a disc brake. *A thorough visual inspection can only be accomplished by removing the friction pads.* ● **SEE FIGURE 101–2** for an example of a disc brake pad that shows usable lining thickness, but is severely cracked and *must* be replaced.

NOTE: Some disc brake pads use a heat barrier (thermo) layer between the steel backing plate and the friction material. The purpose of the heat barrier is to prevent heat from transferring into the caliper piston where it may cause the brake fluid to boil. Do not confuse the thickness of the barrier as part of the thickness of the friction lining material. The barrier material is usually a different color and can be distinguished from the lining material.

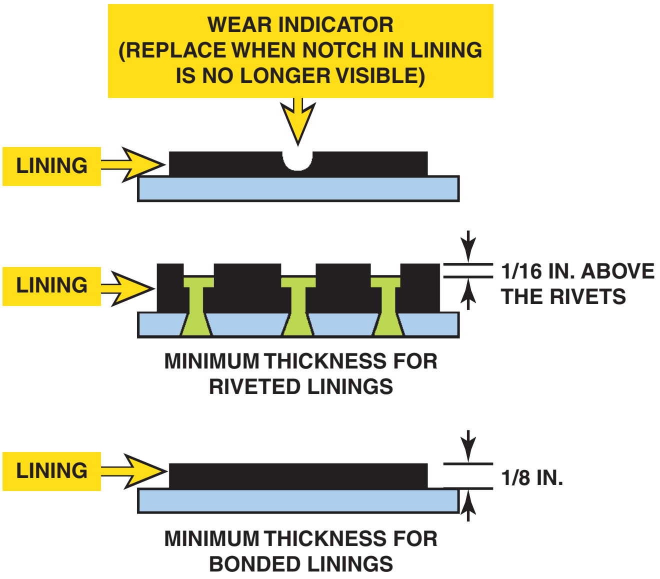

FIGURE 101–1 Minimum thickness for various types of disc brake pads. Pad wear sensors often make a "chirping" sound when the vehicle is moving if the pads are worn. Do not confuse that noise for a defective wheel bearing or other fault.

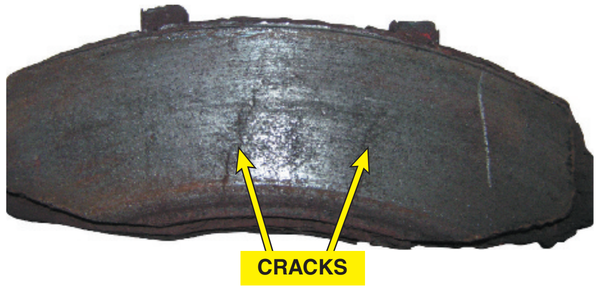

FIGURE 101–2 This cracked disc brake pad must be replaced even though it is thicker than the minimum allowed by the vehicle manufacturer.

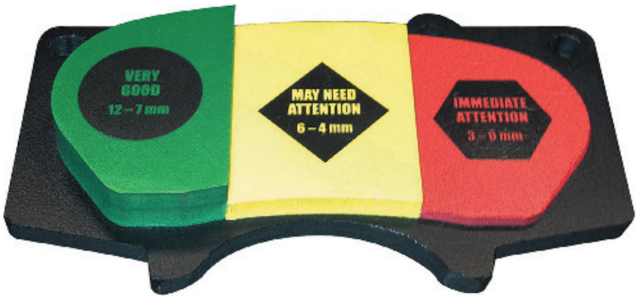

FIGURE 101–3 A brake pad display used by shops to help customers visualize the measurements taken when their brakes were inspected.

Green—Good is 0.25 to 0.50 inch (7–12 mm)

Yellow—May need attention is 0.16 to 0.24 inch (4–6 mm)

Red—Immediate attention required is less than 0.12 inch (3 mm)

TECH TIP

The Bleed and Squirt Test

If you suspect a brake is not being fully released, simply loosen the bleeder valve. If brake fluid squirts out under pressure, then the brake is being kept applied. Look for a defective flexible brake hose.

If the vehicle is off the ground, the wheels should be able to be rotated with the brakes off. If a wheel is difficult or hard to turn by hand and is easy to turn after opening the bleeder valve, then there is a brake fluid restriction between the master cylinder and the brake.

Some disc brake pads may show more wear on the end of the pad that first contacts the rotor as compared to the trailing end of the pad. This uneven wear is caused by the force between the pad and the abutment (slide area). In designs that place the caliper piston exactly in the center of the leading edge of the pad that first contacts the rotor as it is revolving through the caliper, pressures are often one-third higher than the average pressure exerted on the entire pad. The result of this higher pressure is greater wear. ● **SEE FIGURES 101–3 AND 101–4**.

DISC BRAKE CALIPER SERVICE

REMOVAL Hoist the vehicle and remove the wheel(s). Note the caliper mount position as shown in ● **FIGURE 101–5** before removing the caliper. Knowing whether the caliper is "rear-mount" position or "forward-mount" position is often needed when purchasing replacement calipers. Following the procedure specified in service information, remove the caliper assembly and the rotor. ● **SEE FIGURES 101–6 THROUGH 101–10**.

INSPECTION Caliper replacement is indicated if any of these conditions are found:

- brake fluid is in and around the piston boot area
- boot is damaged or a fluid leak is visible

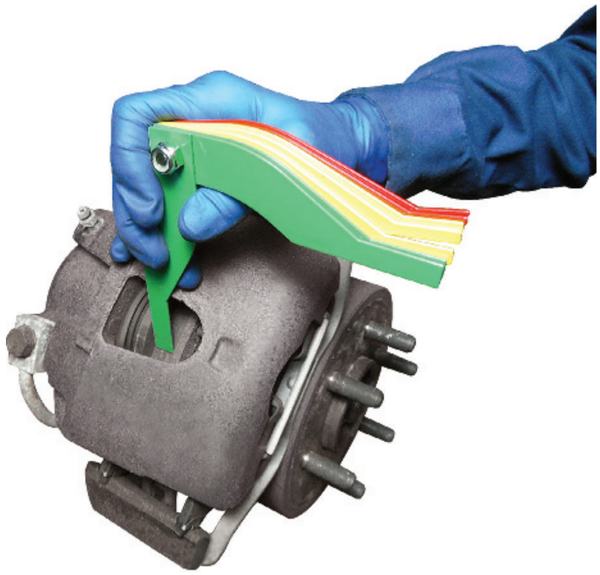

FIGURE 101–4 Most disc brake calipers have a brake inspection opening. For a thorough inspection, however, the caliper should be removed and the entire braking system thoroughly inspected. This inspection opening does allow the use of a brake pad thickness gauge so that the pad thickness can be documented on the work order.

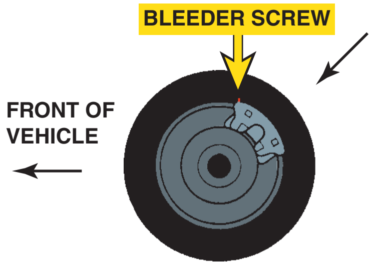
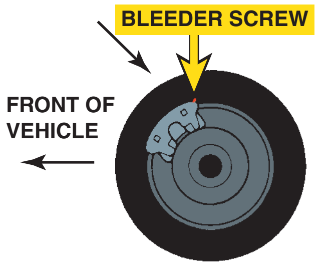


REAR-MOUNT CALIPER POSITION



FORWARD-MOUNT CALIPER POSITION

FIGURE 101–5 Both rear- and forward-mounted calipers have the bleeder valve at the top. Some calipers will fit on the wrong side of the vehicle, yet not be able to be bled correctly because the bleeder valve would point down, allowing trapped air to remain inside the caliper bore. If both calipers are being removed at the same time, mark them “left” and “right.”

- caliper piston is frozen or stuck
- bleeder screw is stripped or broken off
- mounting threads on the caliper are damaged or stripped

NOTE: Uneven disc brake pad wear (inside pad compared to the outside pad) can be caused if the caliper is unable to “float.”

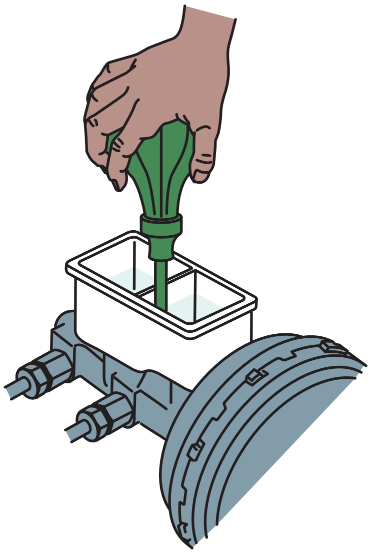


FIGURE 101–6 Many manufacturers recommend removing one-half of the brake fluid from the master cylinder before servicing disc brakes. Use a squeeze bulb and dispose of the used brake fluid properly.

CASE STUDY

Three Brake Jobs in 40,000 Miles

A service technician was asked to replace the front disc brake pads on a Chevrolet Malibu because the sensors were touching the rotors and making a squealing sound. This was the third time that the front brakes needed to be replaced. Previous brake repairs had been limited to replacement of the front disc brake pads only.

When the caliper was removed and the pads inspected, it was discovered that a part of one pad had broken and a piece of the lining was missing. ● **SEE FIGURE 101–11**.

Then the technician spotted something at the rear of the vehicle that told the whole story—a trailer hitch.

The owner confirmed that a heavy jet ski was towed in hilly terrain. The technician recommended overhauling the front disc brake calipers to prevent the possibility of the front pads dragging. The technician also recommended an inspection of the rear brakes. The rear brakes were glazed and out of adjustment. The technician received permission to replace the rear brakes, replace both front calipers, and install quality disc brake pads. When the customer returned, the technician advised the customer to use a lower gear in the transmission on long downhill roads to help keep the brakes from overheating and failing prematurely.

Summary:

Complaint—The front calipers needed replacement more often than expected.
Cause—The front calipers were not retracting and the rear brakes were not working as designed.
Correction—Front calipers were replaced and the rear brakes were serviced. Plus the owner was advised to use the gear selector when descending long grades to reduce the load on the brakes.

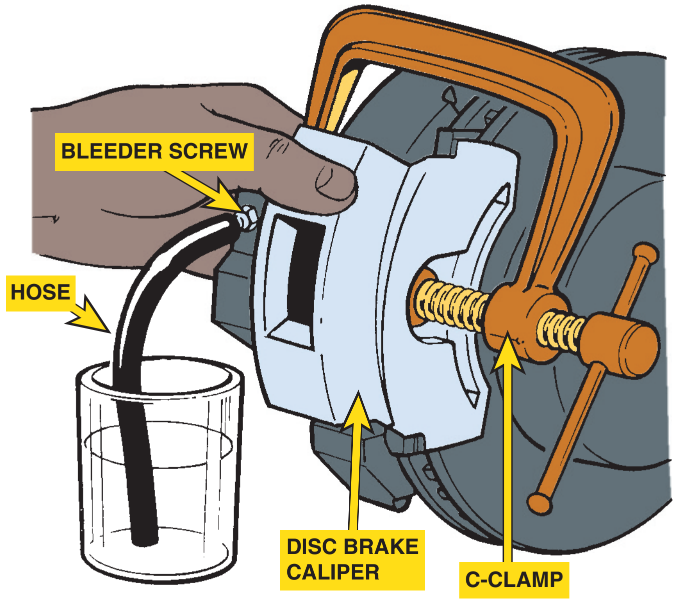

FIGURE 101–7 Most manufacturers recommend that the bleeder valve be opened and the brake fluid forced into a container rather than back into the master cylinder reservoir. This helps prevent contaminated brake fluid from being forced into the master cylinder where the dirt and contamination could cause problems.

TECH TIP

Using "Loaded Calipers" Saves Time

Many technicians find that disassembly, cleaning, and rebuilding calipers can take a lot of time. Often the bleeder valve breaks off or the caliper piston is too corroded to reuse. This means that the technician has to get a replacement piston, caliper overhaul kit (piston seal and boot), plus the replacement friction pads and hardware kit.

To save time (and sometimes money), many technicians are simply replacing the old used calipers with "loaded calipers." **Loaded calipers** are remanufactured calipers that include (come loaded with) the correct replacement friction pads and all the necessary hardware. ● **SEE FIGURE 101–12**.

Therefore, only one part number is needed for each side of the vehicle for a complete disc brake overhaul.

CALIPER INSTALLATION

CALIPER MOUNT SERVICE When the hydraulic force from the master cylinder applies pressure to the disc brake pads, the entire caliper tends to be forced in the direction of rotation of the rotor. All calipers are mounted to the steering knuckle or axle housing. ● **SEE FIGURE 101–13**.

All braking force is transferred through the caliper to the mount. The places where the caliper contacts the caliper mount are called the **abutments**, **reaction pads**, or **ways**. The sliding surfaces of the caliper support should be cleaned with a wire brush and coated with a synthetic grease or antiseize compound according to manufacturer's recommendations. ● **SEE FIGURE 101–14**.

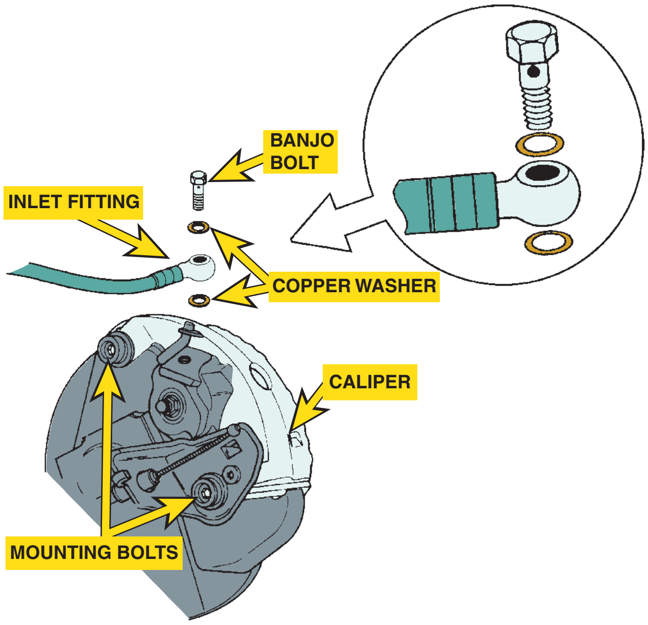

FIGURE 101–8 Many calipers use a hollow "banjo bolt" to retain the flexible brake line to the caliper housing. The fitting is usually round like a banjo. The copper washers should always be replaced and not reused.

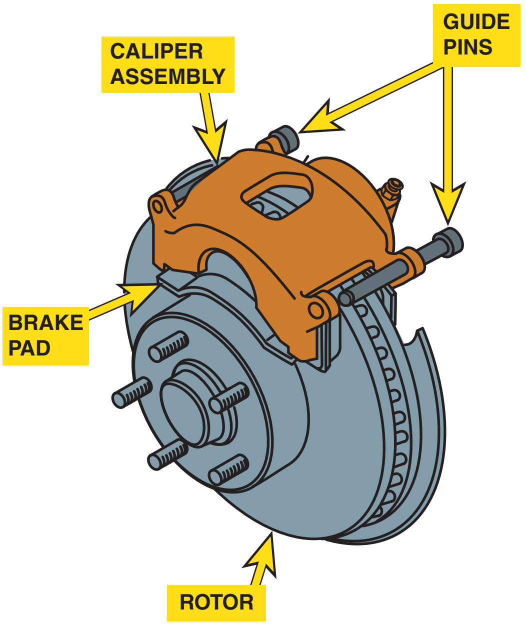

FIGURE 101–9 Caliper retaining bolts are often called guide pins. These guide pins are used to retain the caliper to the steering knuckle. These pins also slide through metal bushings and rubber O-rings.

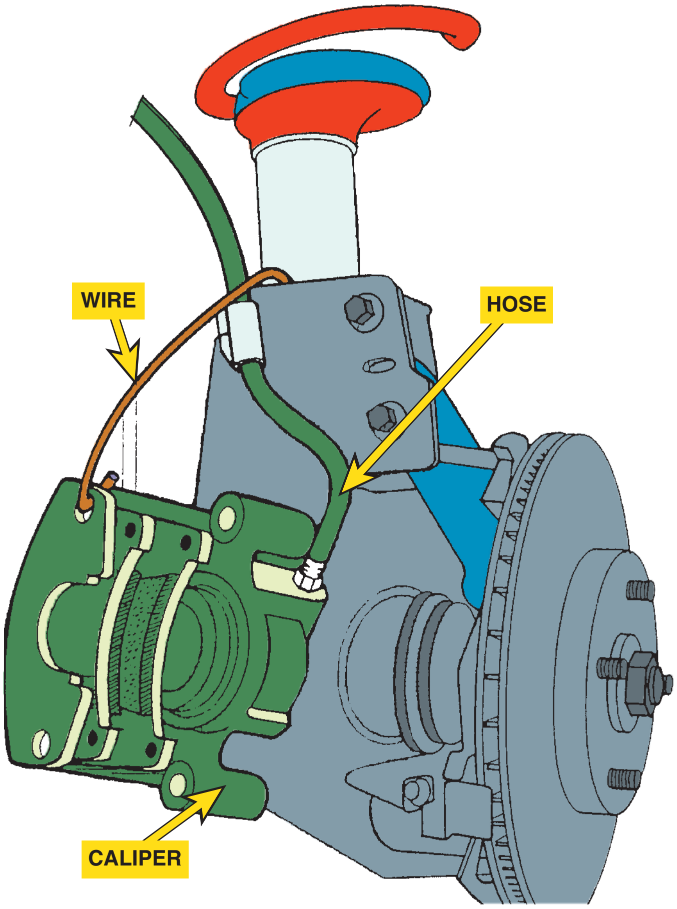
As the vehicle ages and the brakes are used thousands of times, these abutments (pads) can wear, causing too much clearance between the caliper and the mounting. When this occurs, the caliper often rotates against the abutment when the brakes are first applied, making a loud "knocking" noise. If this occurs, the service technician can repair this type of wear in two ways:

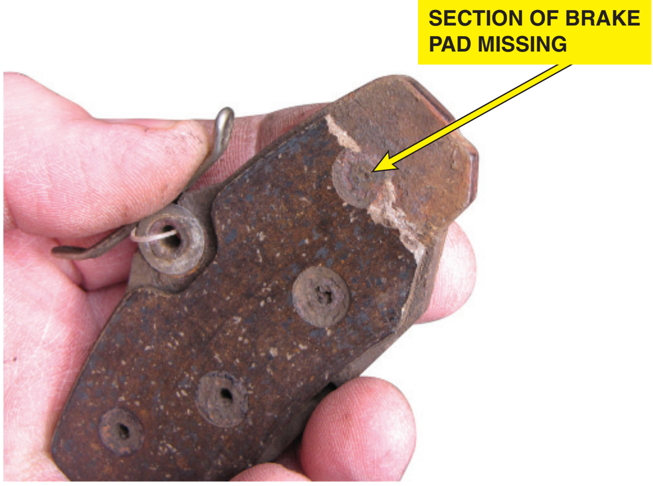
METHOD 1 Replace the entire steering knuckle or caliper mount. This is the recommended method and also the most expensive. Replacement caliper mounts or knuckles may also be difficult to locate.

METHOD 2 Some aftermarket brake supply companies offer "abutment repair kits" that include oversize slides.



WIRE
HOSE
CALIPER

FIGURE 101–10 If the caliper is not being removed, it must be supported properly so that the weight of the caliper is not pulling on the flexible rubber brake line. A suitable piece of wire, such as a coat hanger, may be used.



SECTION OF BRAKE PAD MISSING

FIGURE 101–11 These pads were found to be cracked and a section was missing from a part of one pad.

ROTATING PISTONS BACK INTO THE CALIPER Many disc brake calipers used on the rear wheels require that the piston be rotated to reseat the pistons. When the parking brake is applied, the actuating screw moves the piston outward, forcing the pads against the disc brake rotor. The piston is kept from rotating because of an antirotation device or notches on the inboard pad and piston.

When the disc brake pads are being replaced, use a special tool to rotate the piston back into the brake calipers. Insert the tip of the tool in the holes or slots in the piston. Exert inward

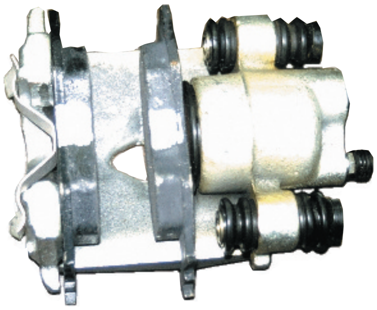


FIGURE 101–12 A loaded caliper includes all hardware and shims with the correct pads all in one convenient package, ready to install on the vehicle.

FILE ABUTMENTS (REACTION PADS) IF NECESSARY TO OBTAIN CLEARANCE

FIGURE 101–13 Floating calipers must be able to slide during normal operation. Therefore, there must be clearance between the caliper and the caliper mounting pads (abutments). Too little clearance will prevent the caliper from sliding and too much clearance will cause the caliper to make a clunking noise when the brakes are applied.

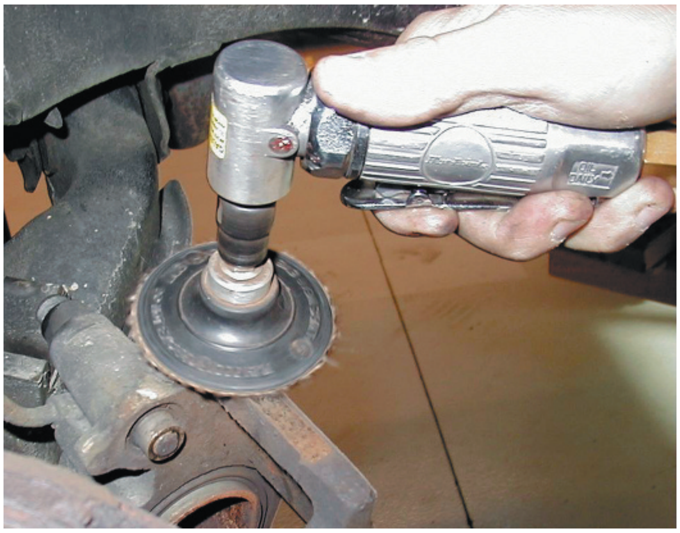

FIGURE 101–14 Using an air-powered sanding disc to clean the caliper mount pads.

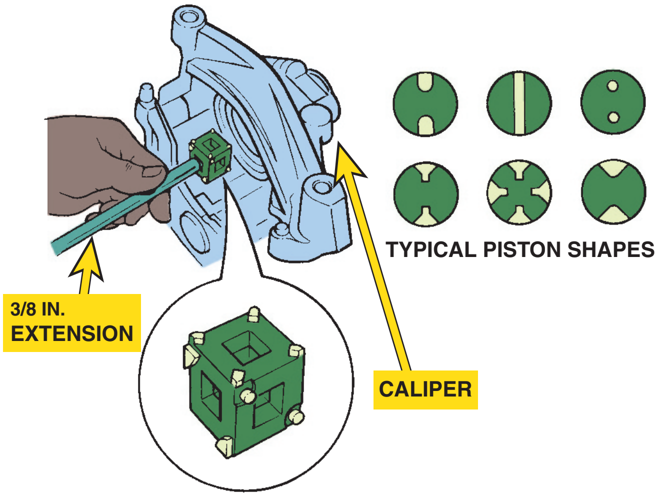

FIGURE 101–15 Determine which face of the special tool best fits the holes or slots in the piston. Sometimes needle-nose pliers can be used to rotate the piston back into the caliper bore.

pressure while turning the piston. Make sure that the piston is retracting into the caliper and continue to turn the piston until it bottoms out.

NOTE: Some pistons are activated with left-handed threads.

After replacing the pads back into the caliper, check that the clearance does not exceed 1/16 inch (1.5 mm) from the rotor. Clearance greater than 1/16 inch may allow the adjuster to be pulled out of the piston when the service brake is applied. If the clearance is greater than 1/16 inch, readjust by rotating the piston outward to reduce the clearance. ● **SEE FIGURE 101–15**.

TEST-DRIVE AFTER BRAKE REPLACEMENT After installing replacement disc brake pads or any other brake work, depress the brake pedal several times before driving the vehicle. This is a very important step! New brake pads are installed with the caliper piston pushed all the way into the caliper. The first few brake pedal applications usually result in the brake pedal going all the way to the floor. The brake pedal must be depressed ("pumped") several times before enough brake fluid can be moved from the master cylinder into the calipers to move the piston tight against the pads and the pads against the rotors.

CAUTION: Never allow a customer to be the first to test-drive the vehicle after brake work has been performed.

BEDDING-IN REPLACEMENT BRAKE PADS Some manufacturers recommend that their replacement brake pads be **bedded-in** or **burnished** before returning the vehicle to the owner.

TECH TIP

Always Double-Check Your Work

Whenever reassembling brakes, it is easy to twist the flexible brake hose as shown in ● **FIGURE 101–16**. To prevent possible brake hose failure and possibly an accident, always double-check that the ribs on the brake hose are straight. The ribs allow the service technician to easily spot if the hose has been twisted.

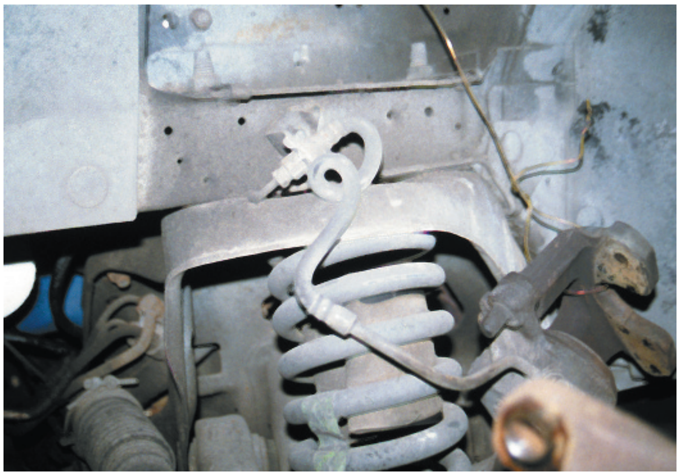

FIGURE 101–16 Note the twisted flexible brake line. This was caught by an automotive instructor before the brake work on the vehicle was completed. The twisted brake line can cause brake hose failure if not corrected.

TECH TIP

Increasing Pad Life

Many vehicles seem to wear out front disc brakes more often than normal. Stop-and-go city-type driving is often the cause. Driving style, such as rapid stops, also causes a lot of wear to occur.

The service technician can take some actions to increase brake pad life that are easier than having to cure the driver's habits. These steps include the following:

1. Make sure the rear brakes are properly adjusted and working correctly. If the rear brakes are not functioning, all of the braking is accomplished by the front brakes alone.

NOTE: Remind the driver to apply the parking brake regularly to help maintain proper rear brake clearance on the rear brakes.

2. Use factory brake pads or premium brake pads from a known manufacturer. Tests performed by vehicle manufacturers show that many aftermarket replacement brake pads fail to deliver original equipment brake pad life.

After installing new pads, perform the following steps:

STEP 1 Make 6 to 10 brake applications from approximately 35 MPH (56 km/h) with moderate brake pedal force.

STEP 2 Make an additional two to three hard brake applications from approximately 45 MPH (72 km/h).

NOTE: Do not allow the vehicle to come to a complete stop. After preforming these brake applications, allow the brakes to cool completely before driving again.

This break-in procedure helps the replacement pads to conform to the rotor and helps cure the resins used in the manufacture of the pads. Failure to properly break in new pads according to the manufacturer's recommended procedure could result in a hard brake pedal complaint from the driver and/or reduced braking effectiveness.

Even if the brake pad manufacturer does not recommend a break-in procedure, high-speed stops and overheating of the brakes should be avoided as much as possible during the first 50 to 100 stops.

DISC BRAKE SQUEAL CORRECTION

CAUSES OF BRAKE SQUEAL Disc brakes tend to create brake noise (squeal). The cause and correction of brake noise is a major concern for both the vehicle manufacturers and the service technicians. The greatest customer complaint about brake work involves brake noise. Noise is caused by moving air, which is a result of moving brake components.

CORRECTING DISC BRAKE SQUEAL Brake squeal can best be *prevented* by careful attention to details whenever servicing any disc brake. Some of these precautions include the following:

- **Keep the disc brake pads clean.** Grease on brake lining material causes the friction surface to be uneven. When the brakes are applied, this uneven brake surface causes the brake components to move.
- **Use factory-type clips and anti-squeal shims.** The vehicle manufacturer has designed the braking system to be as quiet as possible. To assure that the brakes are restored to like-new performance, all of the original hardware should be used. Many original equipment brake pads use **constrained layer shims (CLS)** on the back of the brake pads. These shims are constructed with dampening material between two layers of steel. ● **SEE FIGURE 101–17**.

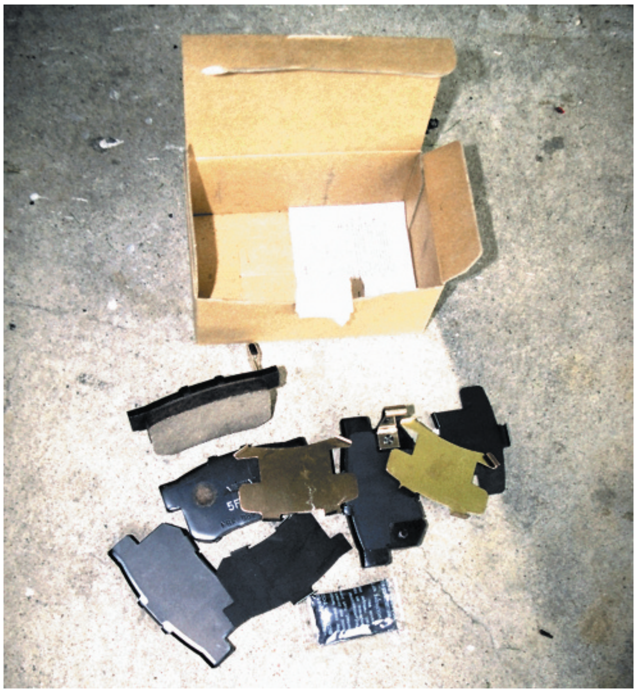

FIGURE 101–17 For best braking performance, purchase replacement disc brake pads that include all clips and shims specified by the vehicle manufacturer. Some pads even come with a package of the specified grease to use on the shims to reduce the possibility of brake noise.

NOTE: Many aftermarket disc brake pads do *not* include replacement hardware that usually includes noise-reducing shims and clips. One of the advantages of purchasing original equipment (OE) disc brake pads is that they usually come equipped with all necessary shims and often with special grease that is recommended to be used on metal shims.

- **Lubricate all caliper slide points as per manufacturer's recommendation.** Lubrication of moving or sliding components prevents noise from being generated as the parts move over each other. Many vehicle manufacturers recommend one or more of the following greases:
  1. **Lithium-based brake grease**
  2. **Silicone grease**
  3. **Molybdenum disulfide (MOS_2) grease** ("Molykote"), often referred to as "moly" grease
  4. **Synthetic grease** (usually **polyalphaolefin [PAO]**) sometimes mixed with graphite, Teflon, and/or MOS_2
  5. **Antiseize compound**

  The grease should be applied on both sides of shims used between the pad and the caliper piston.

CAUTION: Grease should only be applied to the nonfriction (steel) side of the disc brake pads.

- **Machine the brake rotor as little as possible and with the correct surface finish.** Machining the brake rotor reduces its thickness. A thinner rotor will vibrate at a different frequency than a thicker rotor. For factors that can help or hurt brake squeal. ● **SEE CHART 101–1**.

Vehicle manufacturers also change brake pad (lining) composition and the shape of the pads to help eliminate brake noise. The change of shape changes the frequency of the sound. Noise is vibration, but much of the vibration generated is not heard because the noise is beyond the normal frequency to be heard. Most people can hear from 20 to 20,000 cycles per second (called hertz). To stop brake noise, the manufacturer can change the frequency of the vibration to above or below the hertz range that can be heard. ● **SEE FIGURE 101–18**.

FACTOR	INCREASE NOISE	REDUCE NOISE
Brake pad thickness	Thinner (worn) pads	Thicker (new) pads
Rotor (disc) thickness	Thinner (worn) rotor	Thicker (new) rotor
Brake pad material	Harder	Softer
Lubrication of parts	Dry—not lubricated	Properly lubricated
Dampening	No dampening	Dampening material behind the pads
Pad mounting	Pad tabs not bent over	Pad tabs securely crimped
Antirattle clips	Worn, defective, or not lubricated	New and properly lubricated

CHART 101–1

The causes of brake noise can have many reasons and corrections.

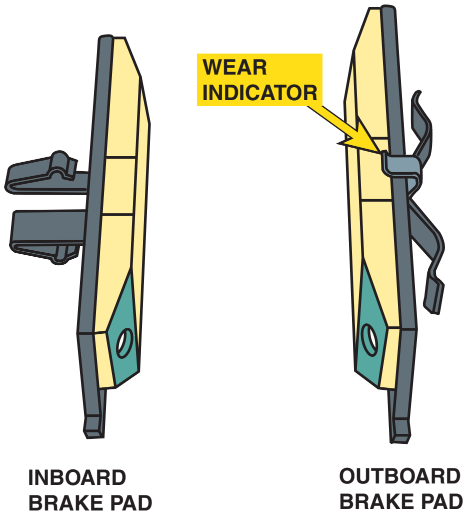

FIGURE 101–18 Notice the beveled pads. The shape of the pad helps reduce brake noise.

NOTE: All metal-to-metal contacts *must* be lubricated to help prevent brake noise.

DISC BRAKE SYMPTOM GUIDE

PULLS TO ONE SIDE DURING BRAKING Possible causes of this include the following:

1. Incorrect or unequal tire pressures
2. Front end out of alignment
3. Unmatched tires on the same axle
4. Restricted brake lines or hoses
5. Stuck or seized caliper or caliper piston
6. Defective or damaged shoe and lining (grease or brake fluid on the lining, or a bent shoe)
7. Malfunctioning rear brakes
8. Loose suspension parts
9. Loose calipers

BRAKE ROUGHNESS OR CHATTER (PEDAL PULSATES) Possible causes of this include the following:

1. Excessive lateral runout of rotor
2. Parallelism of the rotor not within specifications
3. Wheel bearings not adjusted correctly
4. Rear drums out of round
5. Brake pads worn to metal backing plate

EXCESSIVE PEDAL EFFORT Possible causes of this include the following:

1. Binding or seized caliper mounting
2. Binding brake pedal mechanism
3. Improper rotor surface finish
4. Malfunctioning power brake
5. Partial system failure
6. Excessively worn shoe and lining
7. Piston in the caliper stuck or sluggish
8. Fading brakes due to incorrect lining

EXCESSIVE PEDAL TRAVEL Possible causes of this include the following:

1. Partial brake system failure
2. Insufficient fluid in the master cylinder
3. Air trapped in the system
4. Bent shoe and lining
5. Excessive pedal effort
6. Excessive parking brake travel (four-wheel disc brakes, except Corvette)

DRAGGING BRAKES Possible causes of this include the following:

1. Pressure trapped in the brake lines (to diagnose, momentarily open the caliper bleeder valve to relieve the pressure)
2. Restricted brake tubes or hoses
3. Improperly lubricated caliper mounting system
4. Improper clearance between the caliper and torque abutment surfaces
5. Check valve installed in the outlet of the master cylinder to the disc brakes

FRONT DISC BRAKES VERY SENSITIVE TO LIGHT BRAKE APPLICATIONS Possible causes of this include the following:

1. Metering valve not holding off the front brake application
2. Incorrect lining material
3. Improper rotor surface finish
4. Check other causes listed under "PULLS"

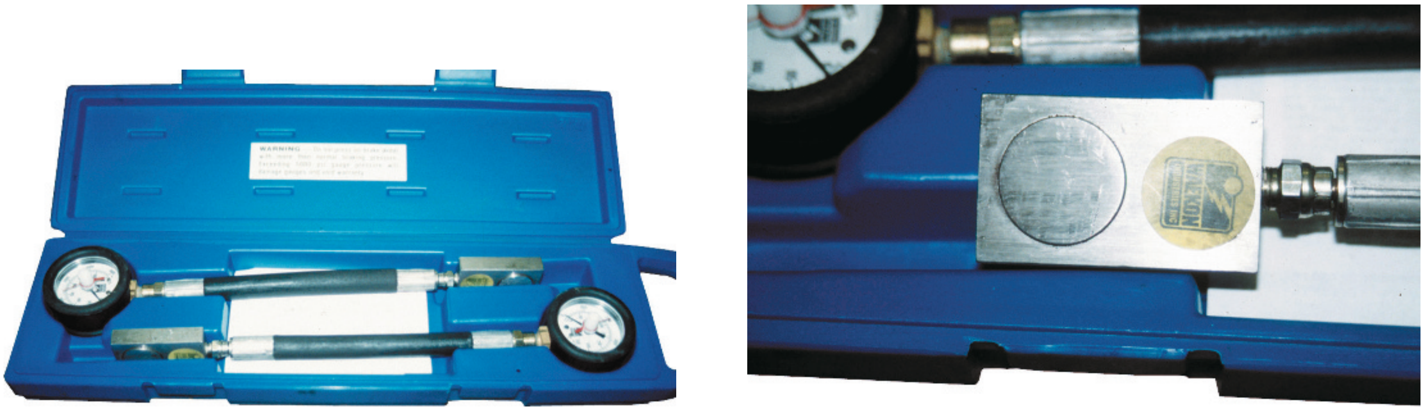
REAR DRUM BRAKES SKIDDING UNDER HARD BRAKE APPLICATIONS Possible causes of this include the following:

1. Proportioning valve
2. Contaminated rear brake lining
3. Caliper or caliper piston stuck or corroded

TECH TIP

Pressure Testing Can Help Find Problems

A stuck caliper or caliper slide is often difficult to see or diagnose as a problem because the movement of the broken pads is so little. Using a pressure gauge between the caliper piston and the rotor (inboard) or between the rotor and the caliper (outboard) can tell the service technician if there is a difference between the left and the right side brakes. ● **SEE FIGURE 101–19**.



(a)

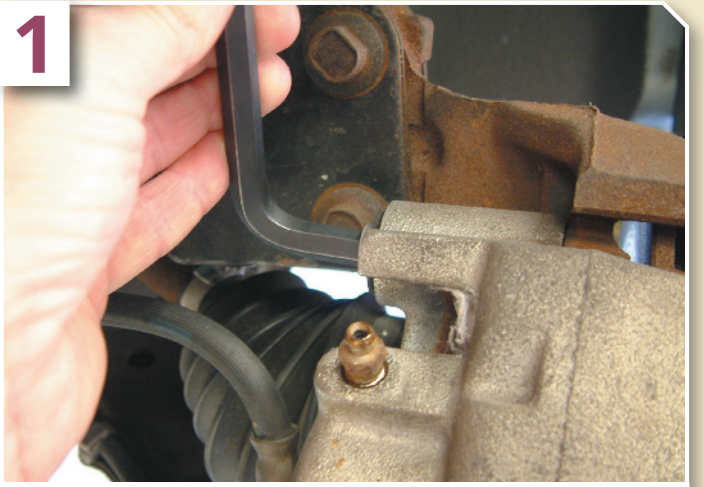
(b)

FIGURE 101–19 (a) A brake pressure tester. (b) The small "pads" can be placed between the caliper piston and the rotor to check for applied pressure and inserted between the caliper and the rotor on the outside of the rotor to test the pressure—the pressure should be the same if the caliper is able to slide on its pins or slides.

DISC BRAKE SERVICE

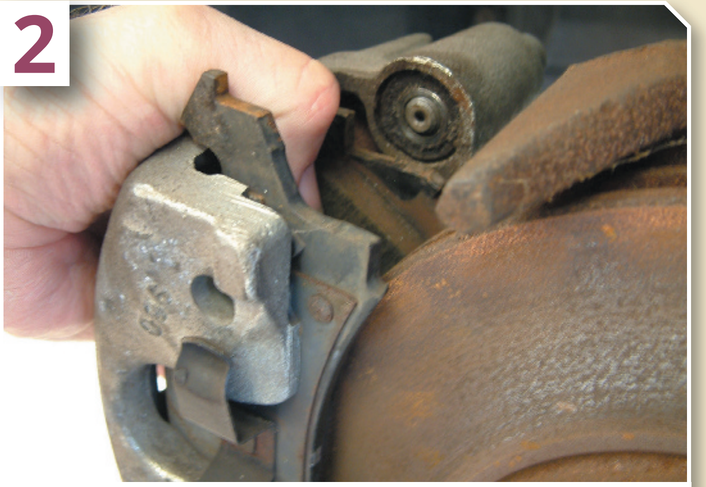
STEP BY STEP

1



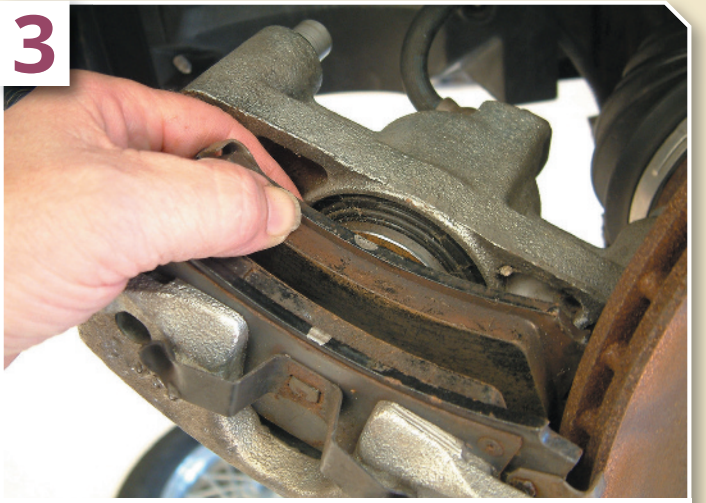
Use a hex wrench to remove the caliper mounting bolts.

2



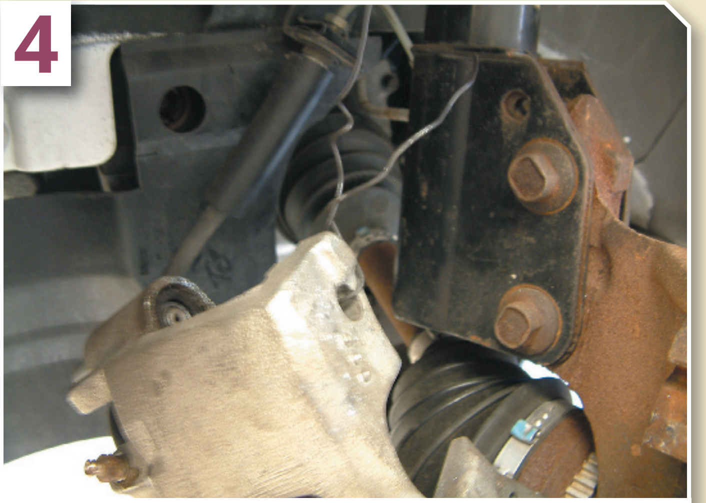
Remove the caliper and pads from the brake rotor.

3



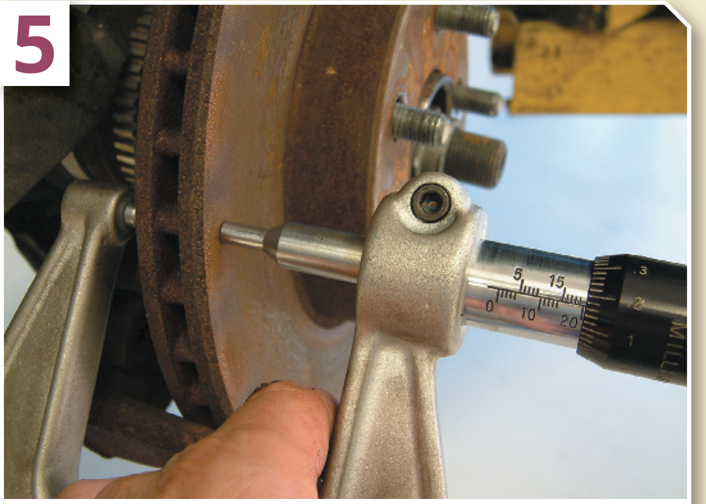
Remove the brake pads from the caliper.

4



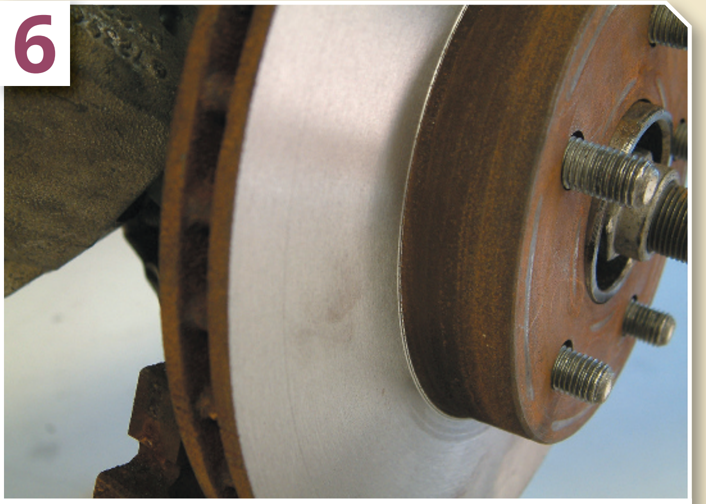
Hang the caliper with wire or a hook. Do not let the caliper hang from the brake hose.

5



Measure the rotor thickness and machine or replace, if necessary.

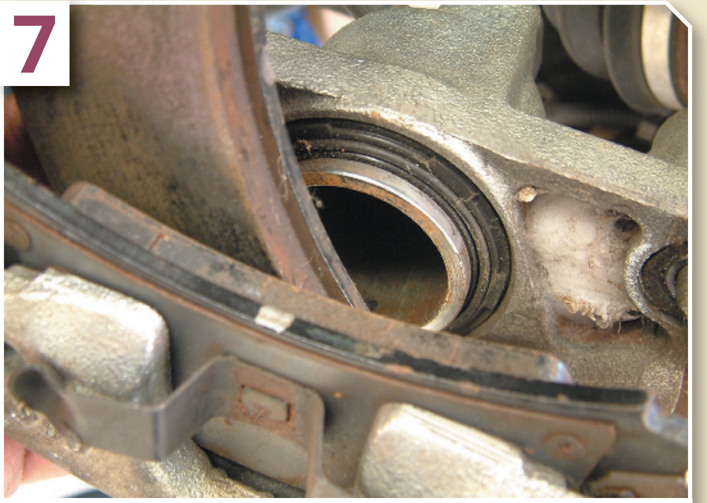
6



Clean the rotor and install it on the hub.

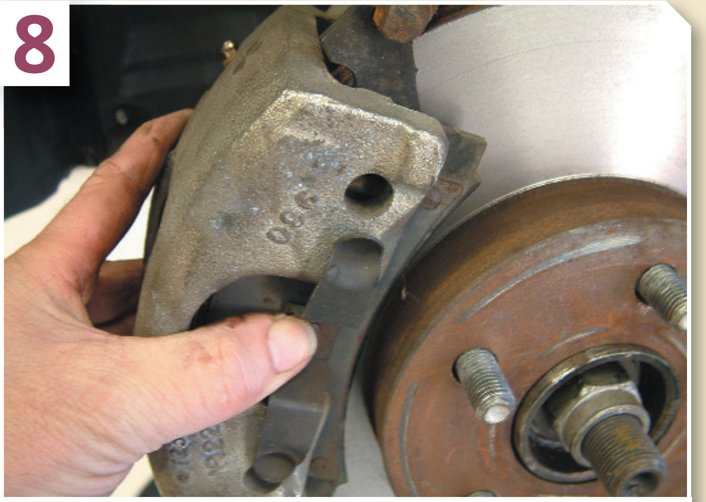
DISC BRAKE SERVICE

7



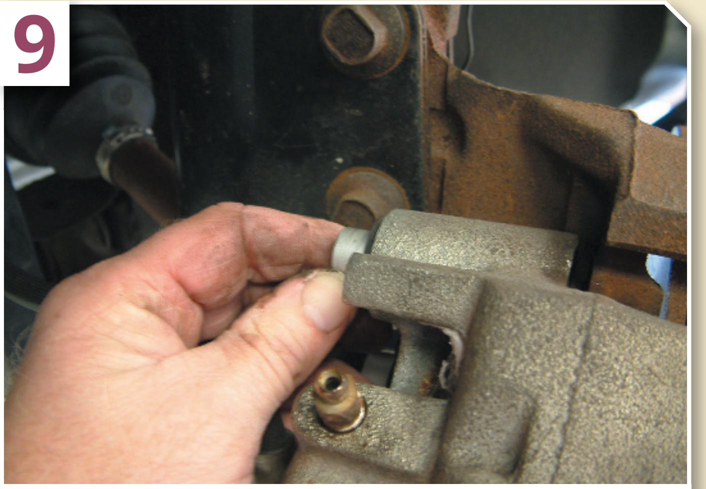
Bottom the piston and install the new brake pads.

8



Slide the caliper and new pads into position on the rotor and steering knuckle.

9



Install and torque the caliper mounting bolts to factory specifications.

REVIEW QUESTIONS

1. Describe how to do a disc brake visual inspection.
2. What is a banjo bolt?
3. Explain what causes disc brake squeal and list what a technician can do to reduce or eliminate the noise.
4. Why should the bleeder valve be opened before pushing the piston back into the caliper when replacing brake pads?
5. What factors increase the possibility of brake noise?

CHAPTER QUIZ

1. A vehicle is in for a brake inspection and the red brake warning light is ON. Which of the following actions should the technician *not* take?
   - **a.** Inspect the system for leaks
   - **b.** Test-drive the vehicle
   - **c.** Check brake pedal height
   - **d.** Check the parking brake
2. Uneven disc brake pad wear is being discussed. Technician A says the caliper piston may be stuck. Technician B says the caliper may be stuck on the slides and unable to "float." Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
3. A "chirping" noise is heard while the vehicle is moving forward, but stops when the brakes are applied. Technician A says that the noise is likely caused by the disc brake pad wear sensors. Technician B says the noise is likely a wheel bearing because the noise stops when the brakes are applied. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
4. Technician A says that disc brake pads should be replaced when worn to minimum allowable thickness. Technician B says the pads should be removed and inspected whenever there is a brake performance complaint. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
5. Two technicians are discussing brake pedal pulsation. Technician A says to check the rotor parallelism. Technician B says to check the metering valve. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
6. Technician A says that a loaded caliper includes an overhauled caliper assembly but no brake pads or hardware. Technician B says that a loaded caliper includes the pads and all needed hardware. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
7. Technician A says that brake squeal can be prevented by spraying the disc with lubricant. Technician B says that using factory-type shims can prevent pad squeal. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
8. Technician A says that a lack of lubrication on the back of the disc brake pads can cause brake noise. Technician B says that pads that are not correctly crimped to the caliper housing can cause brake noise. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
9. What should be done after installing new disc brake pads?
   - **a.** Pump the brake pedal several times
   - **b.** Test-drive the vehicle
   - **c.** Replace the rotors
   - **d.** Rotate the piston back into the caliper
10. Which of the following lubricants should be used to lubricate moving or sliding disc brake components?
    - **a.** Silicone grease
    - **b.** Molybdenum disulfide (MOS_2) grease
    - **c.** Synthetic grease
    - **d.** Any of the above

PARKING BRAKE OPERATION, DIAGNOSIS, AND SERVICE

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Discuss parking brake standards.
- Describe parking brake pedals, levers, and handles.
- Explain parking brake linkages.
- Explain front and rear entry parking brake cables.
- Describe drum parking brakes.
- Describe caliper-actuated disc parking brakes.
- Explain how to adjust a parking brake properly.
- Discuss electric parking brakes.

KEY TERMS:

Application cables 1199 • Control cables 1199 • Electric parking brake (EPB) 1204 • Equalizer 1200 • Intermediate lever 1199 • Red brake warning lamp 1198 • Transfer cable 1199 • Vacuum servo 1198

PARKING BRAKE STANDARDS

BACKGROUND Before 1967, most vehicles had only a single master cylinder operating all four brakes. If the fluid leaked at just one wheel, the operation of all brakes was lost. This required the use of a separate method to stop the vehicle in case of an emergency. This alternative method required that a separate mechanical method be used to stop the vehicle using two of the four wheel brakes. After 1967, federal regulations required the use of dual or tandem master cylinders where half of the braking system has its own separate hydraulic system. In case one-half of the system fails, a dash brake warning lamp lets the driver know that a failure has occurred. The term *parking brake* has replaced the term *emergency brake* since the change to dual master cylinder design.

FMVSS 135 According to Federal Motor Vehicle Safety Standard (FMVSS) 135, the parking brake must hold a fully loaded (laden) vehicle stationary on a slope of 20% up or down grade. The hand force required cannot exceed 80 pounds (18 N) or a foot force greater than 100 pounds (22 N). ● **SEE FIGURE 102–1** for a typical parking brake system.

PEDALS, LEVERS, AND HANDLES

Parking brakes are applied by a pedal, a lever, or a handle from inside the vehicle. Foot pedals and floor-mounted levers are the most common means of applying parking brakes. ● **SEE FIGURES 102–2 AND 102–3**. All parking brake controls incorporate a *ratchet* mechanism to lock the brake in the applied position. ● **SEE FIGURE 102–4**.

When service brake friction assemblies are used as the parking brakes, the service brake pedal should be depressed while the parking brake control is set. Applying the service brake increases parking brake holding power because the brake hydraulic system provides the actual application force, which is far greater than the force that can be developed mechanically. The parking brake mechanism simply locks the brakes in position. If the parking brake is operated only by the pedal, lever, or handle, holding power will be reduced, and the cables in the linkage will tend to stretch.

Most parking brakes are applied manually and the release procedure varies with the design of the parking brake control.

and the pedal remains in the depressed position. The pedal is released by a pull or a small T-handle or lever under the dash. This disengages the ratchet mechanism, and allows a return spring to move the pedal to the unapplied position. On some vehicles, the release lever is integrated into the underside of the dash and connects to the release mechanism through a rod or cable. ● **SEE FIGURE 102–5**.

Some vehicles were equipped with a special pedal design that enabled them to meet federal regulations on parking brake holding power while keeping maximum pedal application force within legal limits. This type of pedal had a high leverage ratio and a special ratchet mechanism that locked the brake pedal in the applied position, but allowed the pedal to return after it had been depressed. Two full pedal strokes, or several partial strokes, were required to fully apply the parking brake. The brake was released by a single pull on a T-handle or release lever.

Some vehicles were equipped with a system that required the driver to depress the parking brake pedal to release the parking brake once it was set. The rubber pad on the parking brake pedal usually states “push to release.”

CASE STUDY

Pump to Release?

A customer called and asked a dealer for help because the parking brake could not be released. The service technician discovered that the customer was attempting to release the parking brake by depressing the parking brake pedal, as was done on the customer's previous vehicle. The service technician simply pulled on the release lever and the parking brake was released.

Summary:

Complaint—Customer called the service department and asked for help releasing the parking brake as it would not release.

Cause—The service technician simply pulled on the parking brake release lever to disengage the parking brake.

Correction—No repair was needed except to inform the customer that the parking brake on the new vehicle was released using a release lever and not by depressing the foot-operated parking brake pedal as was used in the owner's previous vehicle.

AUTOMATIC PARKING BRAKE RELEASE Some vehicles with pedal-operated parking brakes have an automatic release mechanism that disengages the parking brake using a **vacuum servo** controlled by an electrical solenoid. ● **SEE FIGURE 102–6**.

A metal rod connects the vacuum servo to the upper end of the parking brake release lever. When the engine is running (to provide vacuum) and the shifter is placed in gear, an electrical contact closes to energize the solenoid and route vacuum to the servo. The servo diaphragm then retracts the rod, which releases the parking brake. ● **SEE FIGURE 102–7**.

PARKING BRAKE WARNING LAMP A **red brake warning lamp** lights on the dash if any of the following events occur:

- On most vehicles, this is the same lamp that lights when there is a hydraulic or brake fluid level problem.
- The warning lamp for the parking brake warns the driver that the parking brake is applied or partially applied. This warning helps prevent damage or overheating to the brake drums and linings that could occur if the vehicle was driven with the parking brake applied.

If the red 'brake' warning lamp is on, check the parking brake to see if it is fully released. If the 'brake' lamp is still on, the parking brake switch may be defective or out of adjustment, the fluid level may be low, or there may be a hydraulic problem.

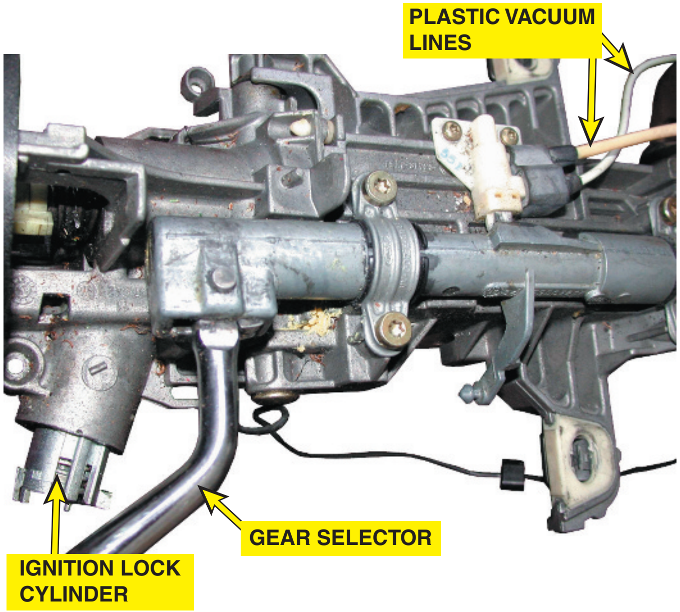

FIGURE 102–7 The two plastic vacuum tubes on the steering column are used to release the parking brake when the gear selector is moved from park into a drive gear.

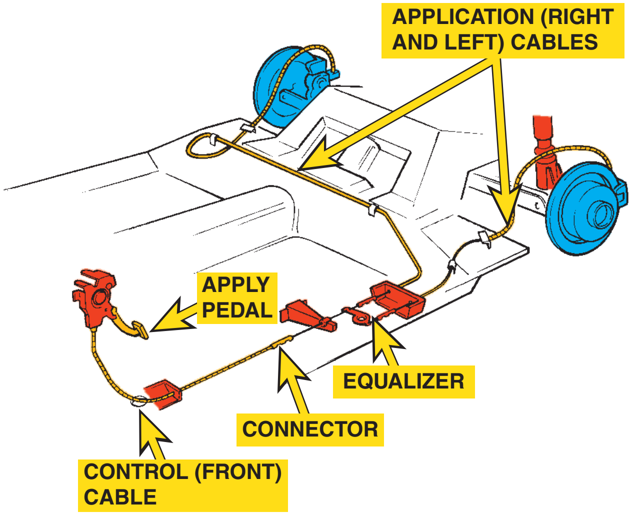

FIGURE 102–8 The cable from the activating lever to the equalizer is commonly called the control cable. From the equalizer, the individual brake cables are often called application cables. These individual cables can usually be purchased separately.

PARKING BRAKE LINKAGES

Parking brake linkages transmit force from the pedal, lever, or handle inside the vehicle to the brake friction assemblies.

LINKAGE RODS Parking brake linkage rods made from solid steel are commonly used with floor-mounted actuating levers to span the short distance to an intermediate lever or an equalizer.

LINKAGE CABLES The typical parking brake cable is made of woven-steel wire encased in a reinforced rubber or plastic housing. The housing is fixed in position at both ends, and is routed under the vehicle through mounting brackets that hold the cable in position, yet allow a small amount of movement. The cable slides back and forth inside the housing to transmit application force, and depending on the linkage design, the outer housing may play a part in parking brake application as well.

Parking brake linkages use control cables, transfer cables, and application cables.

- **Control cables** attach to the parking brake pedal, lever, or handle inside the vehicle.
- A **transfer cable** transmits force to an intermediate lever or equalizer to the application cables.
- The **application cables** use the force passed through the linkage to apply the rear-wheel brake assembly. ● **SEE FIGURE 102–8**.

Parking brake cables are subject to damage from water, dirt, and other debris thrown up under the vehicle by the tires. Most parking brake cables do not require lubrication because they are lined with nylon or Teflon, and any cable housing ends located under the vehicle are protected by rubber or nylon seals.

LINKAGE LEVERS Unfortunately, the amount of physical force a driver can apply to the parking brake control is often not enough to apply the parking brake. For this reason, all parking brake linkages contain one or more levers that increase application force.

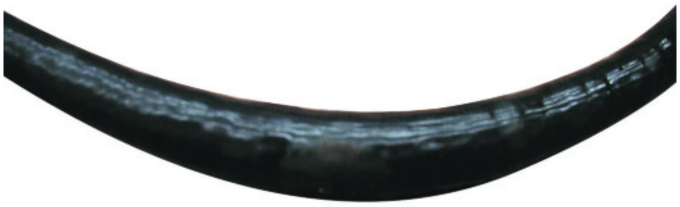

FIGURE 102–9 Notice how rust inside the covering of this parking brake cable has caused the cable to swell.

TECH TIP

Look for Swollen Parking Brake Cables

Always inspect parking brake cables for proper operation. A cable that is larger in diameter in one section indicates that it is rusting inside and has swollen. ● **SEE FIGURE 102–9**.

A rusting parking brake cable can keep the rear brake applied even though the parking brake lever has been released. This can cause dragging brakes, reduced fuel economy, and possible vehicle damage due to overheated brakes.

The parking brake pedals, floor-mounted levers, and pivoting under dash handles described earlier are all types of levers used to increase parking brake application force. A lever in the parking brake linkage under the vehicle is called an **intermediate lever**. ● **SEE FIGURE 102–10**.

To further increase parking brake application force, intermediate levers provide leverage in addition to that supplied by the parking brake control.

LINKAGE EQUALIZERS

In some parking brake linkages, the rods or cables to the two friction assemblies are adjusted separately. If the adjustments are unequal, one brake will apply before the other, preventing full lining-to-drum contact at the opposite wheel and greatly reducing the holding power of the parking brake. To prevent unequal application, most parking brake linkages use an **equalizer** to balance the force from the parking brake control and transmit an equal amount to each friction assembly.

Equalizers come in many shapes and sizes, but the simplest is the cable guide attached to a threaded rod. ● **SEE FIGURE 102–11**. This type of equalizer pivots or allows the inner cable to slide back and forth to even out application force.

Another type of equalizer installs in a long application cable that runs from the linkage at the front of the vehicle to one rear brake. ● **SEE FIGURE 102–12**.

LINKAGE DESIGN

The number of different parking brake linkage designs is almost as great as the number of vehicle models on the road. Most linkages combine intermediate levers and equalizers in various ways and use from one to four cables to actuate the friction assemblies. ● **SEE FIGURE 102–13**.

FRONT AND REAR ENTRY PARKING BRAKE CABLES

The parking brake standard requires that the vehicle be held stationary on a 20% grade facing either uphill or downhill. Many drum parking brake systems attach the parking brake lever on the secondary (rearward) shoe and push the primary (forward facing) brake shoe against the drum. The parking brake cable enters the backing plate from the front of the vehicle (front entry). Because the primary shoe is attached to the secondary shoe on dual-servo brakes, any forward motion of the vehicle tends to wedge the primary shoe into the brake drum *and* force the rear secondary lining also against the drum.

Applying only the forward brake shoe tends to hold the vehicle best when it is being held on a hill with the front pointing downward. To help provide the same holding power for a vehicle being held from backing up, some vehicles reverse the parking brake arrangement for the right side. Instead of having the parking brake cable enter the backing plate from the front, this style has the cable entering from the rear (rear entry). In this case, the right rear brake has the parking brake lever installed on the *primary* shoe.

NOTE: An easy way to remember how to reassemble a drum brake is to realize that the parking brake lever is usually attached to the secondary (rearward) brake shoe. The parking brake strut attaches between the shoes with the spring toward the front of the vehicle (remember, "spring forward").

DRUM PARKING BRAKES

Drum parking brakes are the most common types on vehicles and light trucks. Drum brakes make excellent parking brakes because they have a high static coefficient of friction combined with self-energizing action and, in the case of dual-servo brakes, servo action that increases their application force.

INTEGRAL DRUM PARKING BRAKES

Integral drum parking brakes mechanically apply the rear drum service brakes to serve as the parking brakes. ● **SEE FIGURE 102–14**.

Integral drum parking brakes are the most common type not only because of their natural superiority in this application, but because it is simple and inexpensive to design a parking brake linkage into a drum brake.

The typical integral drum parking brake has a pivoting lever mounted on one brake shoe, and a strut placed between the lever and the other shoe. The strut may be fitted with a spring that takes up slack to prevent noise when the parking brake is not applied. The end of the lever opposite the pivot is moved by the parking brake cable, which enters through an opening in the backing plate. All integral drum parking brakes operate in essentially the same manner. ● **SEE FIGURE 102–15**.

When the parking brake control is operated, the cable pulls the end of the lever away from the shoe it is attached to. The lever pivots at the attaching point and moves the strut to apply the forward shoe. Once the forward brake shoe lining contacts the drum, the strut can travel no farther. The lever then pivots on the strut and forces the lining of the reverse shoe against the drum.

REAR DISC AUXILIARY DRUM PARKING BRAKES

Rear disc service brakes with fixed calipers commonly have a parking brake drum formed into the hub of the brake rotor. ● **SEE FIGURE 102–16**. Inside the drum is a small dual-servo drum brake friction assembly that serves as the parking brake. The rotor splash shield, or a special mounting bracket, provides the backing plate for the friction assembly. Rear disc auxiliary drum parking brakes use the dual-servo friction assembly design because it provides the most holding power, and does so equally in both forward and reverse directions. Dual-servo parking brake friction assemblies operate in essentially the same manner as service brakes except that the wheel cylinder is eliminated and the friction assembly is actuated mechanically. ● **SEE FIGURE 102–17**.

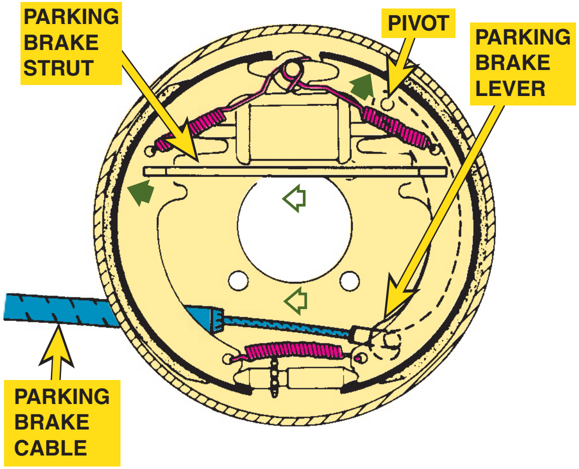

FIGURE 102–15 The parking brake cable pulls on the parking brake lever, which in turn forces the brake shoe against the drum.

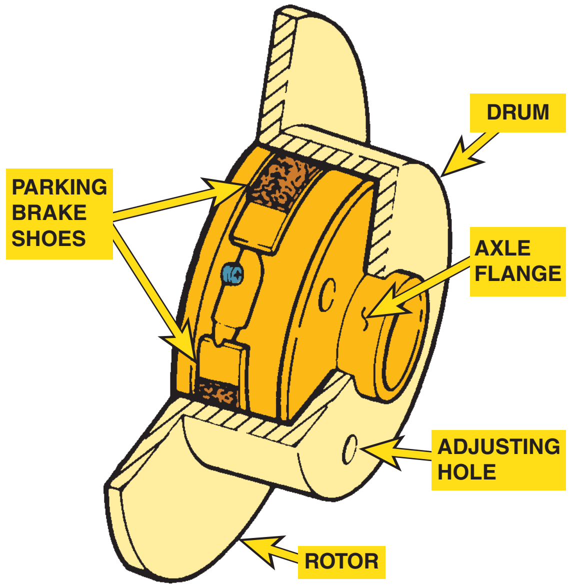

FIGURE 102–16 The inside "hat" of the disc brake rotor is the friction surface for the parking brake shoes.

All rear disc auxiliary drum parking brakes are adjusted manually using a starwheel adjuster, which is reached through an opening in the outside of the drum.

CALIPER-ACTUATED DISC PARKING BRAKES

Caliper-actuated disc parking brakes are used on vehicles whose rear disc brakes are equipped with floating or sliding brake calipers. The single-piston construction of these calipers makes them easier to mechanically actuate than multiple-piston fixed calipers. In this design, a special mechanism in the caliper applies the caliper piston mechanically. The mechanism is operated by a parking brake cable attached to a lever that protrudes from the inboard side of the caliper.

TECH TIP

The Parking Brake "Click" Test

When diagnosing any brake problem, apply the parking brake and count the "clicks." This method works for both hand- and foot-operated parking brakes. Most vehicle manufacturers specify a maximum of 10 clicks. If the parking brake travel exceeds this amount, the rear brakes may be worn or out of adjustment.

CAUTION: Do not adjust the parking brake cable until the rear brakes have been thoroughly inspected and adjusted.

If the rear brake lining is usable, check for the proper operation of the self-adjustment mechanism. If the rear brakes are out of adjustment, the service brake pedal will also be low. This 10-click test is a fast and easy way to determine if the problem is due to rear brakes.

BALL AND RAMP ACTUATION The ball and ramp actuating system found in Ford rear brake calipers has three steel balls located in ramp-shaped detents between two plates. ● **SEE FIGURE 102–18**. One plate has a thrust screw attached that is threaded into an adjuster mechanism in the caliper piston. The other plate is part of the operating shaft that extends out of the caliper. The actuating lever is mounted to the end of this shaft.

As the parking brake cable moves the lever and rotates the operating shaft, the balls ride up the ramps and force the two plates apart. The operating shaft plate cannot move because it butts against the caliper body. The thrust screw plate, which is pinned to the caliper body to prevent it from rotating, is driven away from the operating shaft and toward the rotor where the thrust screw moves the caliper piston to apply the brake. ● **SEE FIGURE 102–19**.

PARKING BRAKE CABLE ADJUSTMENT

PROCEDURE Most manufacturers specify a minimum of three or four and a maximum of eight to ten clicks when applying the parking brake. Check service information for the vehicle being serviced for the exact specifications and adjustment procedures. Most vehicle manufacturers specify that the rear brakes be inspected and adjusted correctly before attempting to adjust the parking brake cable. Always follow the manufacturer's recommended procedure exactly.

Below is a general procedure for parking brake adjustment:

1. Make certain that the rear service brakes are adjusted correctly and the lining is serviceable.

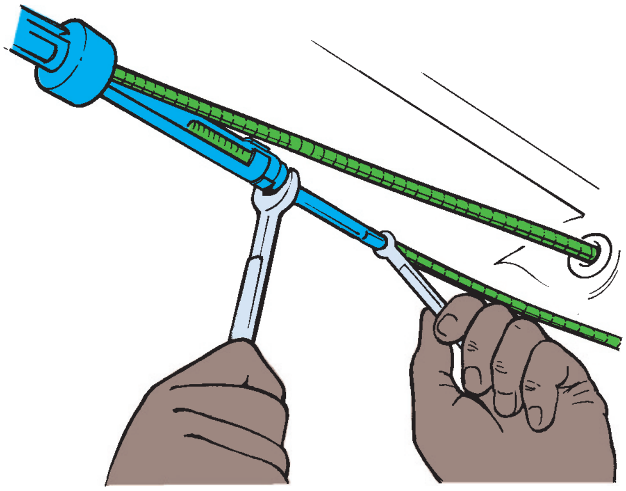

FIGURE 102–20 After checking that the rear brakes are okay and properly adjusted, the parking brake cable can be adjusted. Always follow the manufacturer's recommended procedure.

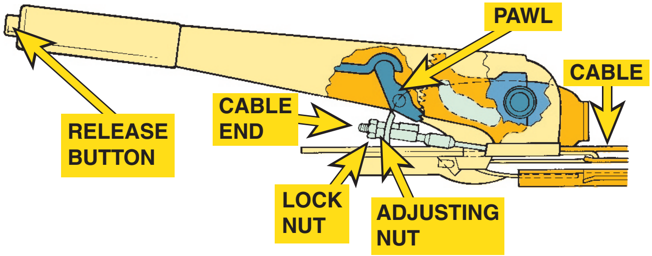

FIGURE 102–21 Many hand-operated parking brakes are adjusted inside the vehicle.

2. With the drums installed, apply the parking brake three or four clicks. There should be a slight drag on both rear wheels.
3. Adjust the cable at the equalizer (equalizes one cable's force to both rear brakes) if necessary until there is a slight drag on both rear brakes. ● **SEE FIGURES 102–20 AND 102–21.**
4. Release the parking brake. Both rear brakes should be free and not dragging. Repair or replace rusted cables or read-just as necessary to ensure that the brakes are not dragging.

NOTE: The rear parking brake adjustment should always be checked whenever replacing the rear brake linings. It may be necessary to loosen the parking brake cable adjustment to allow clearance to get the drum over the new linings. This could happen because someone may have adjusted the parking brake cable during the life of the rear linings. ● SEE FIGURE 102–22.

With new thicker linings, the parking brake adjustment can keep the brake shoes pushed outward toward the drum.

To prevent possible parking brake cable adjustment problems when installing new rear brakes, always observe the following:

1. Both brake shoes should make contact with the anchor pin at the top. If not, check the parking brake cable for improper adjustment or improper installation of the brake shoes.
2. Feel the tension of the parking brake cable underneath the vehicle. It should be slightly loose (with the parking brake "off").
3. Lubricate the parking brake cable to ensure that water or ice will not cause rust or freezing of the cable. This is necessary because even though the parking brake lever is released inside the vehicle, a stuck parking brake cable could cause the linings to remain out against the drums.

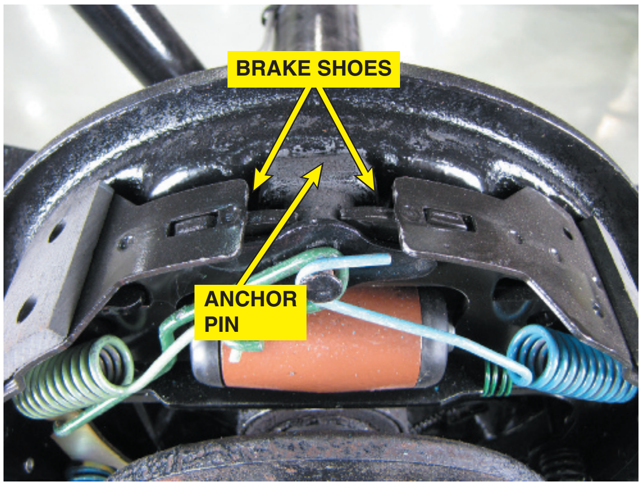

FIGURE 102–22 Always check that the brake shoes contact the anchor pin.

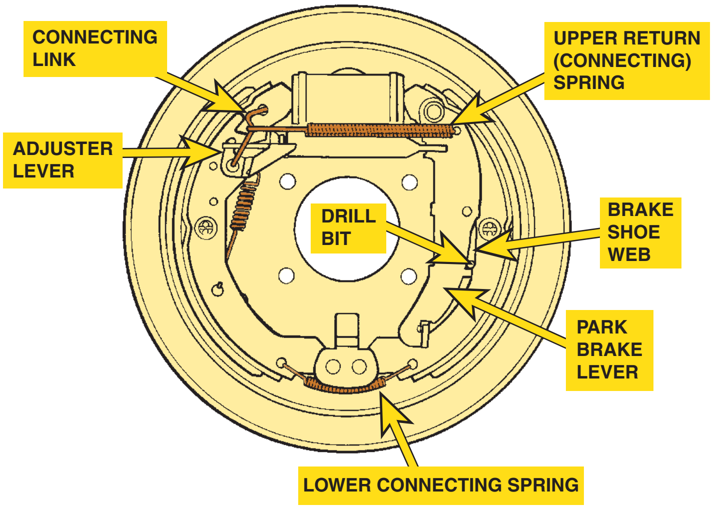

FIGURE 102–23 A 1/8 inch (3 mm) drill bit is placed through an access hole in the backing plate to adjust this General Motors leading-trailing rear parking brake. Adjust the parking brake cable until the drill can just fit between the shoe web and the parking brake lever.

4. If the parking brake needs to be adjusted (will not hold on a hill or requires excessive lever movement), always check and adjust the rear brake adjustment before adjusting the parking brake cable. ● **SEE FIGURE 102–23**.

NOTE: Some vehicles are equipped with an automatic adjusting parking brake lever/cable. Simply cycling the parking brake on/off/on three times is often all that is required to adjust the parking brake cable.

5. Replace any stuck, corroded, or broken parking brake cable.

TECH TIP

The Hose Clamp or Wrench Trick

It is often difficult to remove a parking brake cable from the backing plate due to the design of the retainer. The many fingers used to hold the cable to the backing plate can be squeezed all at once if a hose clamp is used to compress the fingers. A wrench as shown in ● **FIGURE 102–24** can also be used.

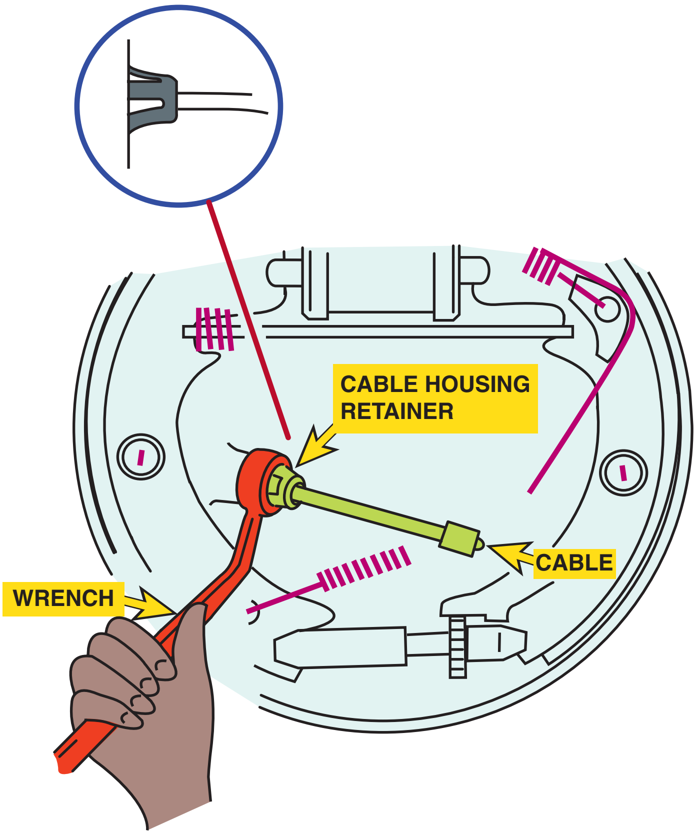

FIGURE 102–24 Many parking brake cables can be removed easily from the backing plate using a 1/2 inch (13 mm) box-end wrench. The wrench fits over the retainer finger on the end of the parking brake cable.

ELECTRIC PARKING BRAKE

TYPES **Electric parking brake (EPB)** systems are available using two different designs including the following:

1. A cable-pulling type that uses an electric motor to pull the parking brake cable rather than a mechanical handle or foot pedal. ● **SEE FIGURES 102–25 THROUGH 102–27**.
2. A more advanced unit uses a computer-controlled motor attached to the brake caliper to activate it.

FIGURE 102–28 The electric parking brake (EPB) control module is used to control the operation of the electric parking brake actuator at each rear wheel.

Some vehicles already use an electric parking brake (EPB) that can be activated when the vehicle stops and then goes off as soon as the gas pedal is pressed, preventing the vehicle from moving while stopped. ● **SEE FIGURE 102–28**.

EPB SERVICE If the vehicle being serviced is equipped with a cable-actuated system, then no special service procedures are needed when replacing rear brakes. However, in many vehicles, the electric parking brake (EPB) is automatically applied when the vehicle is placed in park. There are two ways that a technician can release the EPB including

1. Manually follow a release procedure such as:
   - Place transmission in park (P) or neutral in a vehicle equipped with a manual transmission.
   - Press and hold the EPB switch for five seconds.
   - When the EPB warning light starts to flash, release the EPB switch to deactivate the parking brake.
2. Use a scan tool and follow the on-screen instructions to deactivate the electric parking brake. ● **SEE FIGURE 102–29.**

MACHINING BRAKE DRUMS AND ROTORS

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Describe the types of brake drums.
- Explain the factors that cause drum and rotor damage.
- Discuss brake drum distortion.
- Discuss brake drum removal.
- Discuss “machine to” versus “discard.”
- Explain how to machine a brake drum.
- Discuss disc brake rotors.
- Discuss disc brake rotor distortion.
- Discuss carbon-ceramic rotors.
- Discuss disc brake rotor thickness.
- Discuss when the rotors should be machined.
- Describe rotor surface finish.
- Explain the procedure for qualifying a brake lathe.
- Discuss machining a disc brake rotor.
- Discuss on-the-vehicle rotor machining.

BRAKE DRUMS

CAST-IRON DRUMS Brake drums are constructed of cast iron where the lining contacts the drum, with mild steel centers. The drum is drilled for the lug studs. Cast iron contains approximately 3% carbon, which makes the drum hard, yet brittle. For this reason, it is recommended that any pounding needed to remove drums be done on the center mild steel portion, which, due to its material characteristics, can take this force without damage. This 3% carbon content of the cast iron also acts as a lubricant, which prevents noise during braking. Also, the rubbing surface can be machined without the need of a coolant (as would be required if constructed of mild steel). Because of these properties, cast iron is used on the friction surface of all drums. ● **SEE FIGURE 103–1**.

ALUMINUM DRUMS Even aluminum brake drums use cast iron for the friction surface area. Besides saving weight, aluminum brake drums transfer heat to the surrounding air faster than cast iron or steel.

Brake drums and rotors are the major energy-absorbing parts of the braking system. Friction between the friction material and the drum or rotor creates heat. This heat is absorbed by the drum or rotor and travels from the friction surface to the remainder of the drum or rotor by heat **convection**. As energy continues to be absorbed, the drum or rotor increases in temperature. Airflow across the drum or rotor helps to dissipate the heat and keep the temperature rise under control. ● **SEE FIGURE 103–2**.

BRAKE DRUM AND ROTOR DAMAGE

Besides wear, drums and rotors often experience damage to their friction surfaces. Because drum and rotor damage is caused by extremes of operation, it is most commonly found on front brakes, which experience more severe use than rear brakes.

SCORING **Scoring** is an extreme form of drum and rotor wear consisting of scratches, deep grooves, and a generally rough finish on the friction surface. ● **SEE FIGURE 103–3**.

There are a number of causes for scoring including the following:

1. The most common is brake linings that have worn to the point where a rivet, lining table, or pad backing plate contacts the drum or rotor.

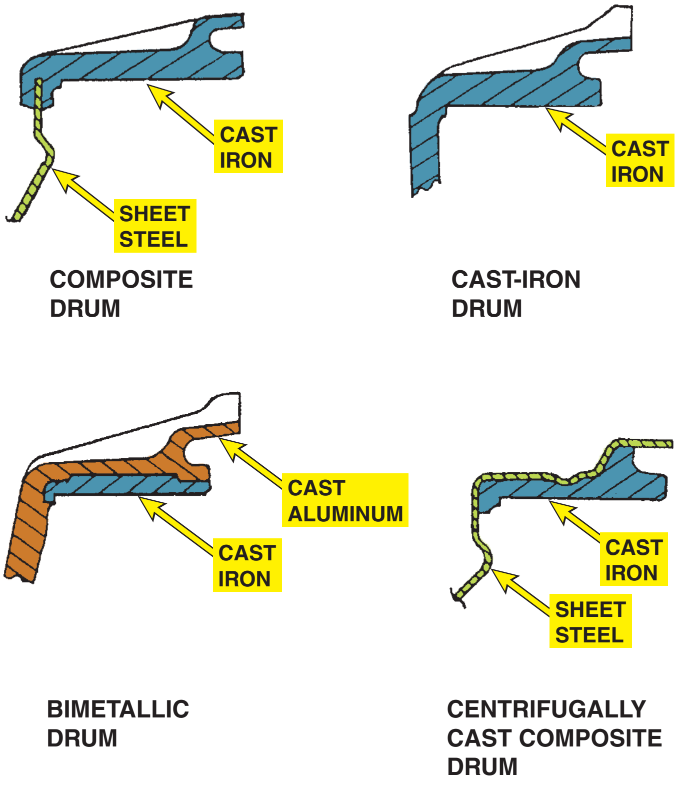

FIGURE 103–1 Types of brake drums. Regardless of the design, all types use cast iron as a friction surface.

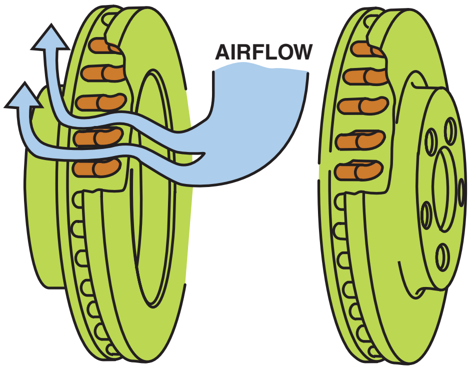

FIGURE 103–2 The airflow through cooling vents helps brakes from overheating.

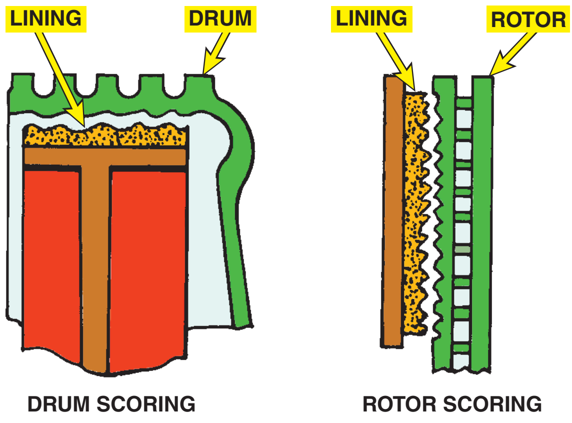

FIGURE 103–3 Scored drums and rotors often result in metal-to-metal contact.

TECH TIP

The Tap Test

Using a steel hammer, lightly tap a brake drum or rotor. It should ring if it is not cracked. If a dull thud is heard, the drum or rotor is likely cracked and should be replaced.

2. Certain friction materials are more likely to score drums and rotors than others, and glazed linings that have hardened from exposure to extreme heat can also cause scoring.
3. Drum brakes are more likely to become scored than disc brakes because their closed construction holds dirt, sand, and abrasive dust inside the friction assembly. This allows the contaminants to be scrubbed repeatedly between the linings and drum.
4. Severe drum scoring often results when metal parts of the friction assembly fatigue, break loose, and are trapped between the linings and drum.

A scored drum or rotor will cause very rapid lining wear, often accompanied by a growling or grinding noise, particularly if there is metal-to-metal contact between the shoe and drum or pad and rotor. Scoring can be machined out of a drum or rotor so long as the amount of metal removed is within the allowable limits.

CRACKING Cracks in a brake drum or rotor are caused by the stress of severe braking or an impact during an accident. ● **SEE FIGURE 103–4**. Generally, drums and rotors that have been previously machined are more susceptible to cracking than new parts. Cracks can appear anywhere on a drum or rotor, although on drums they are most often found near the bolt circle on the web, or at the open edge of the friction surface. Rotors generally crack first at the edge of their friction surfaces.

HEAT CHECKING A lesser form of drum and rotor cracking is called **heat checking**, which consists of many small, interlaced cracks on the friction surface. ● **SEE FIGURE 103–5**. These cracks typically penetrate only a few thousandths of an inch into the metal and seldom pass through the structure of the drum or rotor. Heat checking is usually caused by a driver who leaves one foot on the brake pedal while applying the accelerator with the

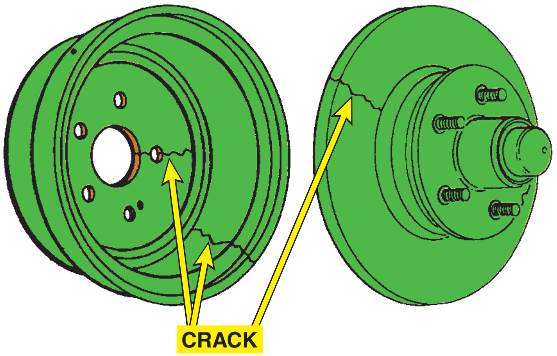

FIGURE 103–4 Cracked drums or rotors must be replaced.

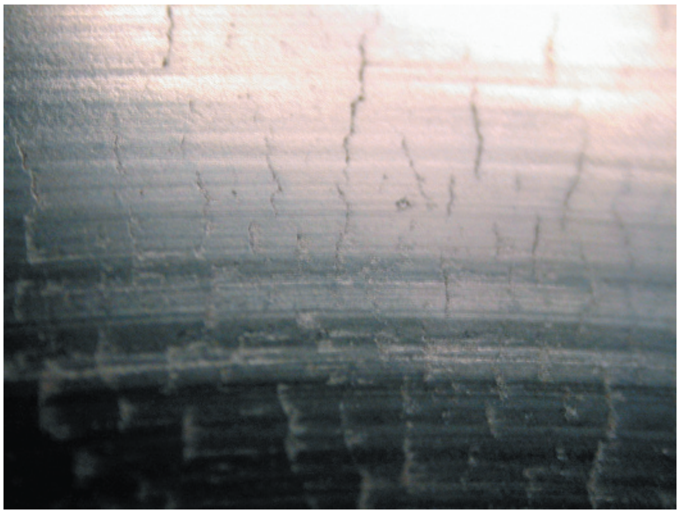

FIGURE 103–5 A heat-checked surface of a disc brake rotor.

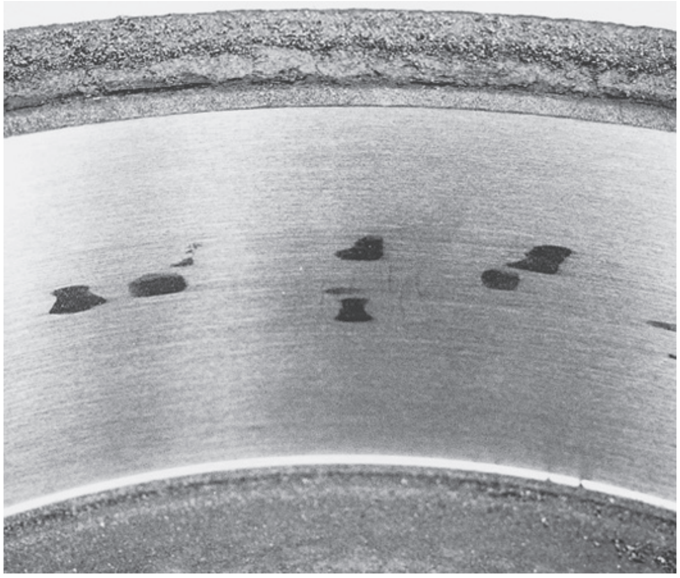

FIGURE 103–6 These dark hard spots are created by heat that actually changes the metallurgy of the cast-iron drum. Most experts recommend replacement of any brake drum that has these hard spots.

other. Heat checking can also be caused by repeated heavy braking or numerous panic stops made in rapid succession.

Light heat checking can often be machined away. In more severe cases, the drum or rotor must be replaced.

HARD OR CHILL SPOTS Earlier it was stated that cast-iron drums and rotors are durable because the friction, heat, and pressure of braking cause a tough "skin" to form on their friction surfaces. However, if brake temperatures become too great, localized impurities in the metal can be burned away, altering the structure of the metal and causing **hard spots**, also called **chill spots**, to appear. Hard spots are roughly circular, bluish gold, glassy-appearing areas on the friction surface. ● **SEE FIGURE 103–6**.

Hard spots create a number of problems including the following:

- They are harder than surrounding areas of the friction surface and do not wear at the same rate. Once the spots begin to stand out from the rest of the friction surface, they cause rapid brake lining wear.
- The friction coefficient of hard spots is less than that of surrounding areas so braking power is reduced or becomes uneven. This can cause the brakes to chatter, or result in a hard or pulsating brake pedal.
- A drum or rotor is more likely to crack in the area of hard spots than elsewhere.

Most vehicle manufacturers recommend that the drum or rotor should be replaced if hard spots are found.

TECH TIP

Storing Drums and Rotors

A common cause of distortion in new brake drums and rotors is improper storage. Drums and rotors should always be stored lying flat; they should never be stood on edge. Distortion of new drums and rotors is common, so they should be routinely checked before installation.

BRAKE DRUM DISTORTION

To ensure smooth brake application without pedal pulsation or other problems, brake drum friction surfaces must remain a fixed position in relation to the shoes. In some cases, a position variation of less than a thousandth of an inch will create braking problems. Distortion puts the drum friction surfaces out of proper alignment with the shoes.

DRUM DISTORTION The friction surface of a brake drum in perfect condition is parallel to the axis of the axle and rotates in a precise circle centered on the axle or hub. All brake drums suffer from distortion during brake operation, but they usually return to their original shape once the brakes are released. When the friction surface does not return to its proper shape, is no longer parallel to the axle, or does not rotate in a precise circle around the axle, the drum is distorted.

BELLMOUTH DRUMS When an open edge of a brake drum friction surface has a larger diameter than the closed edge, the drum is suffering from **bellmouth** distortion. ● **SEE FIGURE 103–7**. Bellmouth distortion is caused by poor drum rigidity combined with high heat and brake application force.

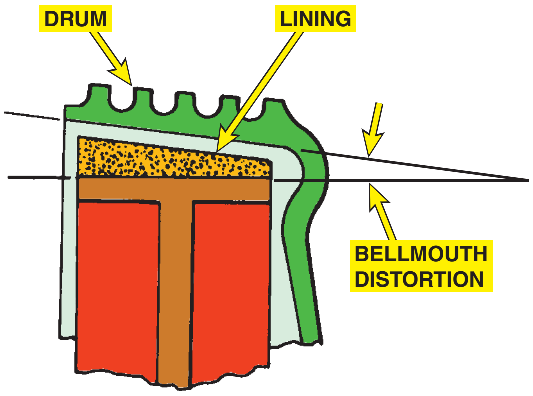

FIGURE 103–7 Bellmouth brake drum distortion.

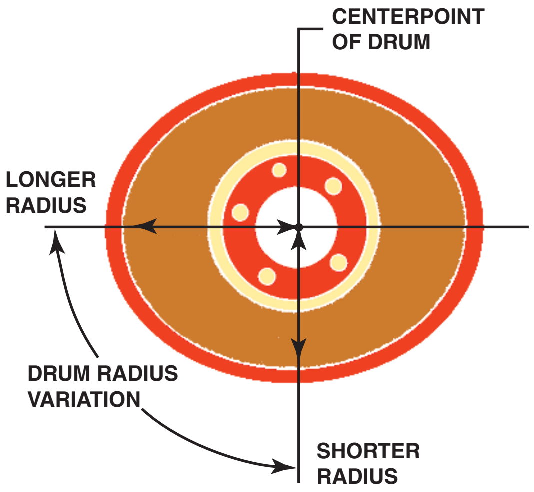

FIGURE 103–8 Out-of-round brake drum distortion.

Bellmouth distortion occurs when a drum suffers mechanical fade and its open edge, unsupported by the drum web, expands more than its closed edge. When the brakes are applied harder to compensate for the fade, the shoes distort the open edge of the drum so far outward that the **elastic limit** of its metal is exceeded. Once this happens, the drum will not return to its original shape after it cools. Repeated occurrences of this process eventually cause the drum to take on a bellmouth shape.

Bellmouth distortion is especially common on wide drums and occurs when a drum has had too much metal machined from it. If new shoes are installed in a bellmouthed drum, brake fade and unusual lining wear will result.

OUT-OF-ROUND DRUMS Uneven heat distribution can sometimes cause **out-of-round** distortion in which the drum radius varies when measured at different points around its circumference. ● **SEE FIGURE 103–8**. Out-of-round distortion can take place when a vehicle drives through a puddle after a series of hard stops and cold water splashed on the brakes causes rapid and uneven cooling of the drums. It can also result if the parking brake is firmly applied after a series of hard stops before the drums have had a chance to cool. In this case, the shoes extend out against the heat-expanded drum and prevent it from contracting to its original circular shape as it cools. Instead, the extended shoes force the drum into an out-of-round shape.

The most common symptom of an out-of-round drum is a pulsating brake pedal when the brakes are applied at all speeds. Out-of-round drums can also cause a vibration or brake chatter at speeds above approximately 40 MPH (60 km/h). In more extreme cases, an out-of-round drum can result in erratic braking action and possibly cause the brakes to grab with every revolution of the wheel.

ECCENTRIC DRUMS **Eccentric distortion** exists when the geometric center of the circle described by the brake drum friction surface is other than the center of the axle or the bolt circle of the drum web. ● **SEE FIGURE 103–9**. This type of distortion causes the drum to rotate with a camlike motion. An eccentric drum will result in a pulsating brake pedal similar to that caused by an out-of-round drum.

Eccentric distortion is often caused by overtightened or unevenly tightened lug nuts or bolts. Not only will this cause an immediate problem, but it can lead to additional problems later. If a vehicle is driven for an extended time with an eccentric drum, the linings may slowly wear the friction surface "round" again. However, as soon as tension on the lug nuts or bolts is released, the drum will relax back to its original shape creating an out-of-round condition that was not apparent before the wheel was removed.

TECH TIP

The Parking Brake Trick

Whenever attempting to diagnose a brake pedal pulsation, drive to a deserted area or parking lot and try stopping the vehicle using the parking brake. If a vibration occurs, the problem is due to a fault with the rear brakes. If a vibration does not occur except when using the service brakes, the problem is most likely due to a fault with the front brakes.

TECH TIP

Mark It to Be Sure

Most experts recommend that brake rotors, as well as drums and wheels, be marked before removing them for service. Many disc brake rotors are directional and will function correctly only if replaced in the original location. A quick-and-easy method is to use correction fluid. This alcohol-based liquid comes in small bottles with a small brush inside, making it easy to mark rotors with an "L" for left and an "R" for right. Correction fluid (also called "white-out" or "liquid paper") can also be used to make marks on wheel studs, wheels, and brake drums to help ensure reinstallation in the same location.

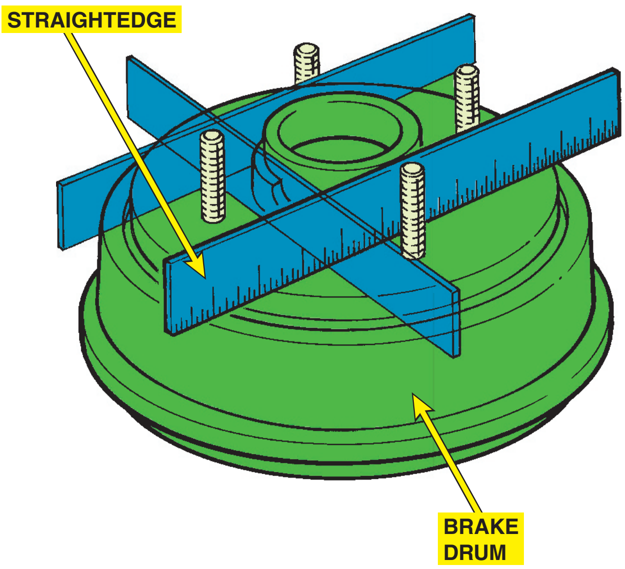

FIGURE 103–10 A straightedge can be used to check for brake drum warpage.

REMOVING DRUMS

Metal clips called **Tinnerman nuts** are installed at the factory to keep the brake drums from falling off during vehicle assembly. These clips can be removed and do not need to be reinstalled since the wheel lug nuts hold onto the brake drum.

The first inspection step after removing a brake drum is to check it for warpage using a straightedge, as shown in ● **FIGURE 103–10**.

A warped drum is often a source of vibration. A brake drum that is out-of-round can cause a brake pedal pulsation during braking.

NOTE: To help diagnose if the front brakes or rear brakes are the cause of the vibration, try slowing the vehicle using the parking brake. If vibration occurs, the problem is due to the rear brakes.

"MACHINE TO" VERSUS "DISCARD"

Brake drums can usually be machined a maximum of 0.060 inch (1.5 mm) oversize (e.g., a 9.500 in. drum could wear or be machined to a maximum inside diameter of 9.560 in.) unless otherwise stamped on the drum. Most brake experts recommend that both drums on the same axle be within 0.010 inch (0.25 mm) of each other. The maximum specified inside diameter (ID) means the maximum wear inside diameter. ● **SEE FIGURE 103–11**.

Always leave at least 0.015 inch (0.4 mm) after machining (resurfacing) for wear. Many manufacturers recommend that 0.030 inch (0.8 mm) be left for wear.

REASONS FOR EQUAL DRUM INSIDE DIAMETER There are several reasons why the service technician should check and make sure that both brake drums on the same axle are close to the same inside diameter (ID).

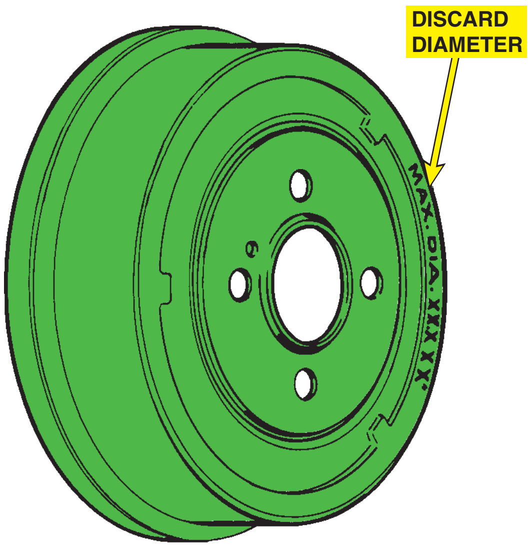

FIGURE 103–11 Discard diameter and maximum diameter are brake drum machining and wear limits.

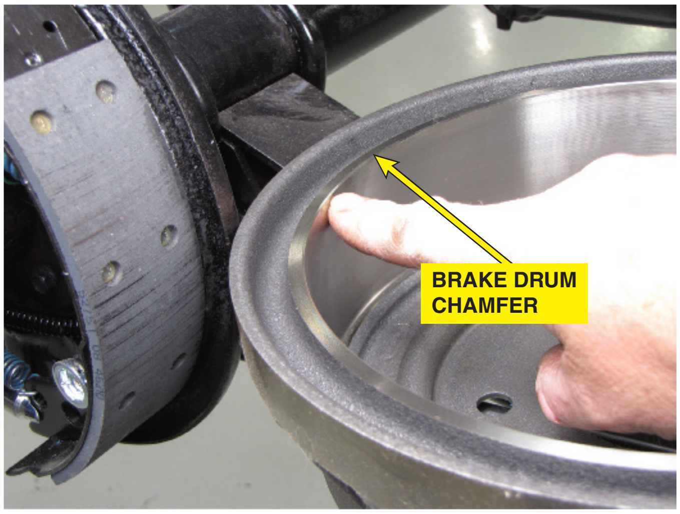

FIGURE 103–12 Most brake drums have a chamfer around the edge. If the chamfer is no longer visible, the drum is usually worn (or machined) to its maximum allowable ID.

TECH TIP

Brake Drum Chamfer

Look at the chamfer on the outer edge of most brake drums. When the chamfer is no longer visible, the brake drum is usually at or past its maximum ID. ● **SEE FIGURE 103–12**. Although this chamfer is not an accurate gauge of the ID of the brake drum, it still is a helpful indicator to the technician.

- **Reason 1.** Since heat is generated by braking, if there is less material (larger ID), the drum will tend to expand more rapidly than a drum with more material (smaller ID).
- **Reason 2.** If one drum expands more than the drum on the other side of the vehicle, unequal braking forces result.
- **Reason 3.** The drum that is larger in ID will expand away from the brake linings more than the other side.

For example:

LEFT DRUM	RIGHT DRUM
9.500 inch	9.560 inch

In this example, when the drums get hot (heavy braking), the vehicle will tend to pull to the left.

MACHINING BRAKE DRUMS

MEASURING A DRUM Before measuring a brake drum, be sure it is not cracked by tapping it with a steel hammer. The brake drum should ring like a bell. If the brake drum makes a dull thud sound, discard the drum. Brake drums are usually measured using a micrometer especially designed for brake drums. ● **SEE FIGURE 103–13**.

Compare the micrometer reading to the discard diameter. Both drums should be measured whenever they are removed for any brake service or inspection.

MACHINING A DRUM PROCEDURE Always start any machining operation by making certain that the brake drum is clean and that excess grease is removed from the hub. If the drum has a hub with bearings, check the outer bearing races (cups) for wear and replace as necessary before placing the drum on the brake lathe. Also, carefully inspect and clean the lathe spindle shaft and cones before use. Use a **self-aligning spacer (SAS)** to be assured of even force being applied to the drum by the spindle nut. Always follow the instructions for the lathe you are using.

Hubless drums use a hole in the center of the brake drum for centering. Always check that the center hole is clean and free of burrs or nicks. Typical drum brake machining steps include the following:

STEP 1 Mount the drum on the lathe and install the silencer band as shown in ● **FIGURES 103–14 AND 103–15**.

STEP 2 Turn the drum by hand before turning on the lathe to be sure everything is clean. Advance the tool bit manually until it just contacts the drum. This is called a **scratch cut**. ● **SEE FIGURE 103–16**.

STEP 3 Stop the lathe and back off the tool bit. Loosen the arbor nut, rotate the drum one-half turn (180 degrees) on the arbor, and retighten the arbor nut. ● **SEE FIGURE 103–17**. Turn the lathe on and make a second scratch cut.

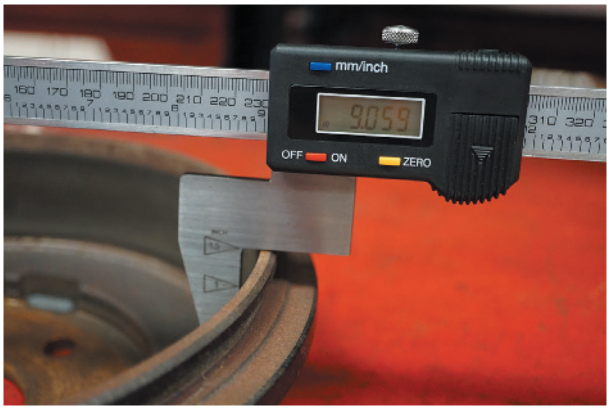

FIGURE 103–13 A digital drum micrometer makes measuring brake drums easy and accurate.

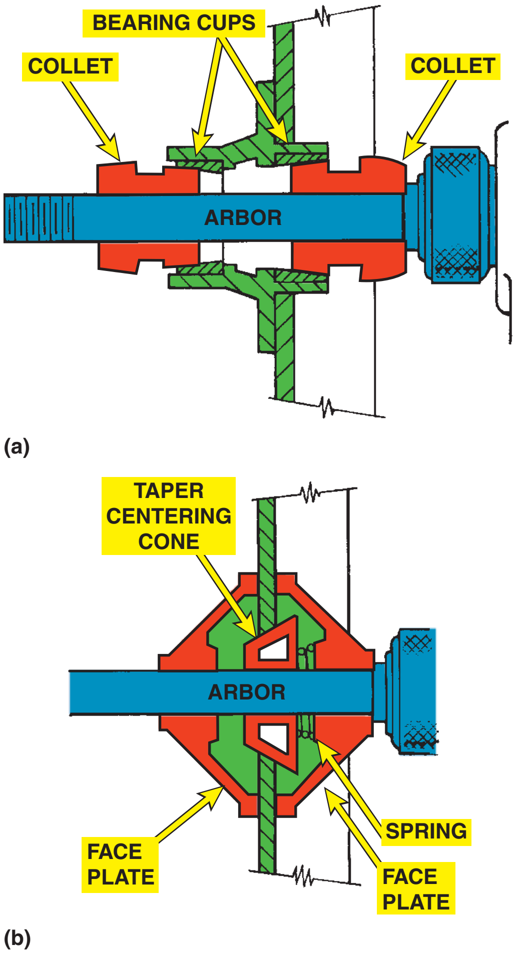

FIGURE 103–14 (a) A rotor or brake drum with a bearing hub should be installed on a brake lathe using the appropriate size collet that fits the bearing cups (races). (b) A hubless rotor or brake drum requires a spring and a tapered centering cone. A faceplate should be used on both sides of the rotor or drum to provide support.

a. If the scratch cuts are side-by-side, the lathe is okay and machining can begin.

b. If the scratch cuts are opposite, remove the drum and check for nicks, burrs, or chips on the mounting surfaces.

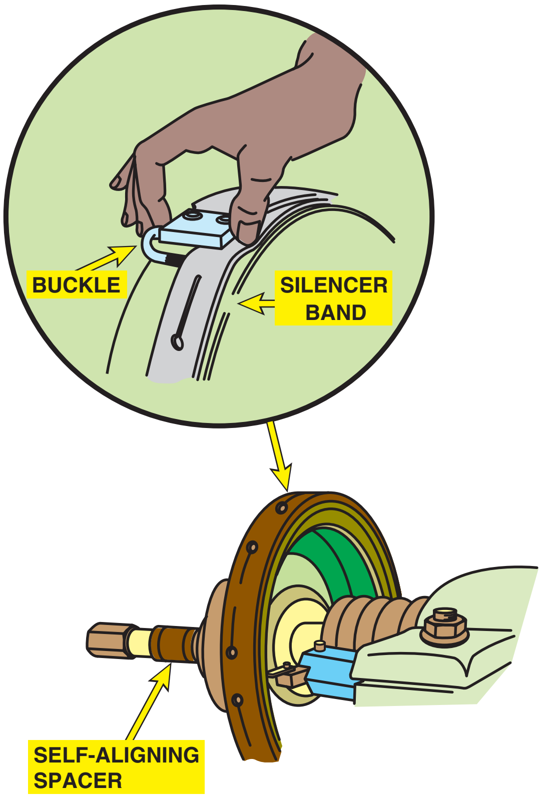
STEP 4 Start the lathe and set the depth of the cut. ● **SEE FIGURES 103–18 AND 103–19**.

The maximum rough cut depends on the lathe type. The minimum cut is usually specified as no less than 0.002 inch (0.05 mm). A shallower cut usually causes the tool bit to slide over the surface of the metal rather than cut into the metal.

● **SEE FIGURE 103–20** for an example of a drum machined without properly positioning the antichatter (vibration) strap.

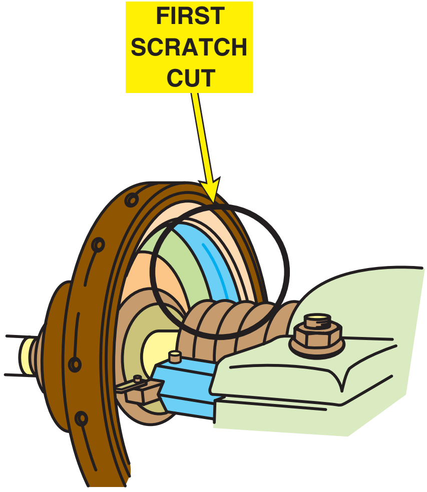
DISC BRAKE ROTORS

CONSTRUCTION Disc brake rotors use cast gray iron at the area that contacts the friction pad. Rotors, also called **discs or disks**, have mass (weight) that absorbs heat. The heavier the rotor, the more heat can be absorbed. Vehicle downsizing has resulted in the use of thinner- and lighter-weight rotors. As



BUCKLE
SILENCER BAND
SELF-ALIGNING SPACER

FIGURE 103–15 A self-aligning spacer (SAS) should always be used between the drum or rotor and the spindle retaining nut to help ensure an even clamping force and to prevent the adapters and cone from getting into a bind. A silence band should always be installed to prevent turning-tool chatter and to ensure a smooth surface finish.



FIRST SCRATCH CUT

FIGURE 103–16 After installing a brake drum on the lathe, turn the cutting tool outward until the tool just touches the drum. This is called a scratch cut.

the weight of the rotor decreases, the less heat the rotor can "store" or absorb, resulting in the rotor getting hotter. As the rotor gets hotter, the rotor expands and "grows" larger where it is the hottest. If the rotor is allowed to cool gradually, the rotor simply returns to its original shape. If, however, the rotor is exposed to water, it may cool rapidly, causing the rotor to distort.

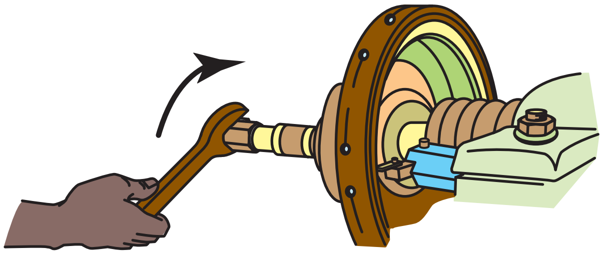


FIGURE 103–17 After making a scratch cut, loosen the retaining nut, rotate the drum on the lathe, and make another scratch cut. If both cuts are in the same location, the drum is installed correctly on the lathe and drum machining can begin.

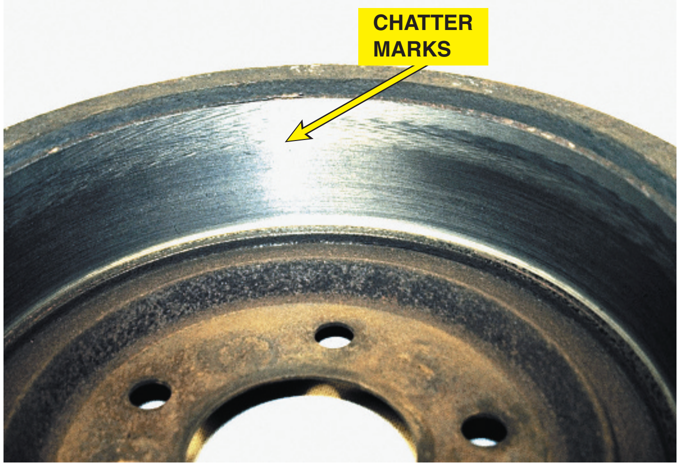

FIGURE 103–20 Notice the chatter marks at the edge of the friction-area surface of the brake drum. These marks were caused by vibration of the drum because the technician failed to wrap the dampening strap (silencer band) over the friction-surface portion of the brake drum.

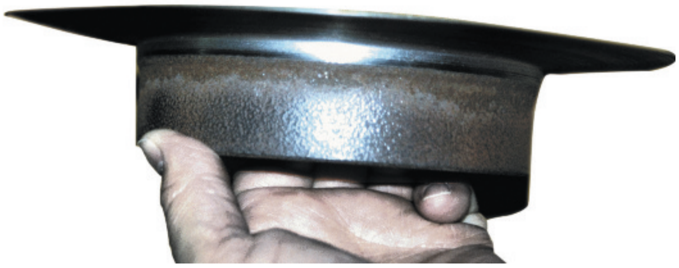

FIGURE 103–21 This excessively worn (thin) rotor was removed from the vehicle in this condition. It is amazing that the vehicle was able to stop with such a thin rotor.

STYLES OR ROTORS Rotors are made in several styles, including the following:

1. **Solid.** These are used on the rear of many vehicles equipped with rear disc brakes and on the front of some small and midsize vehicles. Solid rotors are usually used on the rear where only 20% to 40% of the braking occurs. Solid rotors are much thinner than vented rotors. ● **SEE FIGURE 103–21** for an example of an excessively worn solid rotor.
2. **Vented.** These are used on the front of most vehicles. The internal vanes allow air to circulate between the two friction surfaces of the rotor. Rotors can either be straight vane design, as shown in ● **FIGURE 103–22**, or directional vane design, as shown in ● **FIGURE 103–23**.

COMPOSITE ROTORS **Composite rotors** use a steel center section with a cast-iron wear surface. These composite rotors are lighter in weight than conventional cast-iron rotors. ● **SEE FIGURE 103–24**.

The light weight of composite rotors makes them popular with vehicle manufacturers. However, technicians should be aware that full-contact adapters that simulate the actual wheel

FREQUENTLY ASKED QUESTION

What Does the SAE J2928 Brake Rotor Test Mean?

The society of automotive engineers (SAE) has established a testing procedure that test aftermarket rotors called the SAE J2928 Brake Rotor Thermal Cracking Procedure. During this test, the rotor is subjected to 150 heat cycles from cold to high temperature. The heat cycles are used to test for possible cracking of the rotor. While this test is not mandatory, it can be used to verify that the rotor is able to meet the measurement and thermal capacity of a rotor. It is not an indication that the rotor is certified or approved.

being bolted to the rotor must be used when machining composite rotors. If composite rotors are machined incorrectly, they must usually be replaced.

ALUMINUM METAL MATRIX COMPOSITE ROTORS Some disc brake rotors are manufactured from an aluminum metal matrix composite alloy reinforced with 20% silicon carbide particulate. Aluminum composites combine the light weight and thermal conductivity of aluminum with the stiffness and wear resistance of a ceramic to create a disc brake rotor with excellent heat dissipation and service life.

These rotors can be distinguished from conventional cast-iron rotors in several ways. At first glance, the rotors are silver gray with a dark gray or black transfer layer (from the brake pad) on the rubbing surface. Unlike cast iron, these rotors will show no signs of rust and are nonmagnetic. When removed from the vehicle, the aluminum composite rotors can be further distinguished by their light weight, usually under 6 pounds (2.7 kg) versus over 12 pounds (5.4 kg) for cast-iron rotors on the typical passenger vehicle.

Servicing these rotors is slightly different from cast-iron rotors. The dark transfer layer on the rubbing surface does not harm rotor performance and should not be removed unless the rotor needs to be machined due to being warped. *Aluminum composite disc brake rotors cannot be machined with steel cutting tools!* Carbide tools can be used to machine a single set of aluminum composite rotors. If a shop receives these rotors on a regular basis, a polycrystalline diamond (PCD)-tipped tool is a good investment. Although more expensive initially, the PCD tool can last 100 times longer than a carbide tool.

DISC BRAKE ROTOR DISTORTION

CAUSES OF ROTOR DISTORTION The friction surfaces of a rotor in perfect condition are perpendicular to the axle centerline and have no side-to-side movement. Unlike brake drums, rotors do not suffer distortion as a routine part of brake operation. However, distortion can occur during braking if there is a problem with the friction assembly, such as a frozen caliper piston that creates unequal application force on the two sides of the rotor.

FREQUENTLY ASKED QUESTION

What Does "Cross-Drilled" and "Slotted" Mean?

The terms "cross-drilled" and "slotted" refer to two separate processes. The first procedure involves drilling rows of holes through the friction surfaces of the rotor. The second procedure refers to milling a series of specially machined grooves from the center of the disc toward the edge. When the friction surfaces of a rotor are smooth and flat, there is no means of escape for the gases and dust, which build up between pad and rotor. This is not a huge problem in normal driving, but is an important consideration in street performance applications.

The drill holes (which are sometimes called "gas relief openings") provide an exit route for the dust and gas. The holes are also commonly labeled "cooling holes" because of the improvements they make in this area. Better cooling means less fade during repeated heavy brake application. They also help dissipate water when driving in poor weather. ● **SEE FIGURE 103–25**.

Slotting increases the bite of the pads and is even more effective than cross-drilling in combating the problem known as "out-gassing." This is when, at very high braking temperatures, the bonding agents used in some brake pads produce a gas. Under extreme conditions, this gas can create a gas cushion between pad and rotor, giving a driver a normal pedal feel but reducing the amount of friction being generated. The slots pump away gas and restore full contact. The "micro-shaving" effect of the slots also serves to deglaze the pads and this is why the edges of the slots are not chamfered or "radiused." It also tends to even out the wear across the brake pad faces, increasing the effective contact area.

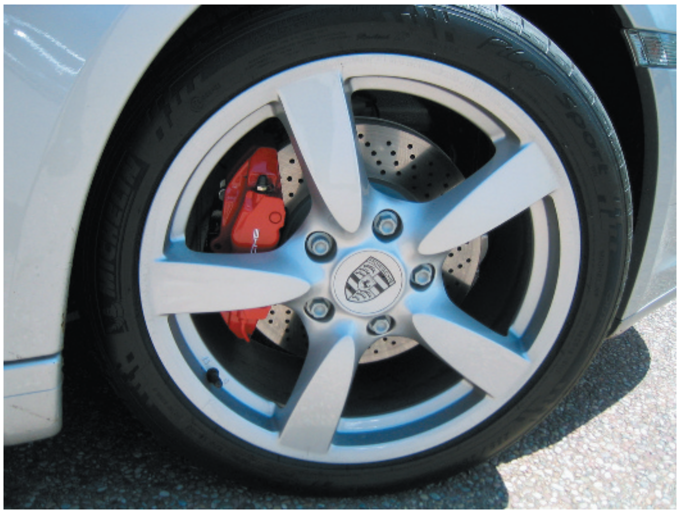

FIGURE 103–25 This Porsche is equipped with high-performance brakes including cross-drilled brake rotors.

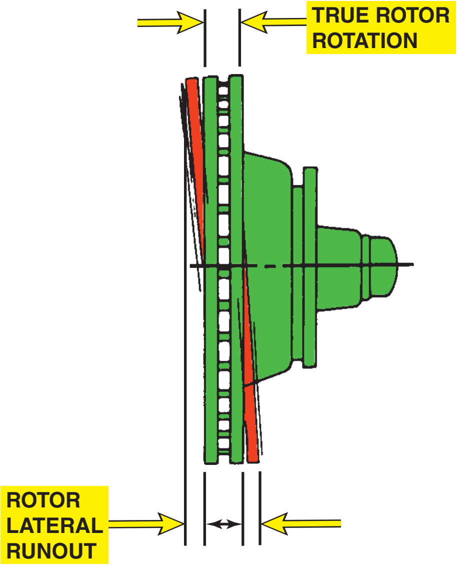

FIGURE 103–26 Brake rotor lateral-runout distortion.

Friction surface distortion is much more significant in a disc brake rotor than in a brake drum because the design of the friction assembly magnifies the effect of any wear. The hydraulic principles dictate that small movements of the large pistons in the brake calipers are converted into large movements of the small pistons in the master cylinder. Even very small amounts of distortion in a disc brake rotor can cause large amounts of pedal pulsation.

ROTOR LATERAL RUNOUT

Lateral runout, often abbreviated **LRO**, is side-to-side wobble of the rotor as it rotates on the spindle. ● **SEE FIGURE 103–26**.

A small amount of runout provides caliper piston knockback that reduces drag when the brakes are not applied. However, if the amount of runout is too great, excessive brake pedal travel and front-end vibration, felt in the steering wheel, will result. In cases of severe runout, a pulsating brake pedal may also be present.

Lateral runout can be caused by several factors. Overtightened or unevenly tightened lug nuts or bolts are a common source of runout on newer vehicles with downsized brake rotors. Extreme heat or rapid temperature variations also cause runout. Inaccurate machining at the factory or in the field is also a common cause of this distortion. Most maximum values range between 0.003 and 0.008 inch (0.05 and 0.20 mm). ● **SEE FIGURES 103–27 AND 103–28**.

ROTOR LACK OF PARALLELISM

Lack of **parallelism**, also called **thickness variation (TV)**, is a variation in the thickness of the rotor when it is measured at several places around its circumference. ● **SEE FIGURE 103–29**.

A rotor with friction surfaces that are not parallel is the most common disc brake cause of a pulsating brake pedal. A lack of rotor parallelism will cause a pedal pulsation when the brakes are applied at all speeds and can also cause front-end vibration during braking. ● **SEE FIGURE 103–30**.

Lack of parallelism can be caused by a soft spot in the rotor casting that wears more rapidly than surrounding areas, but the most common cause is rust buildup on the rotor when the vehicle is not driven for an extended period. The part of the friction surface protected by the brake pads does not rust as much as the

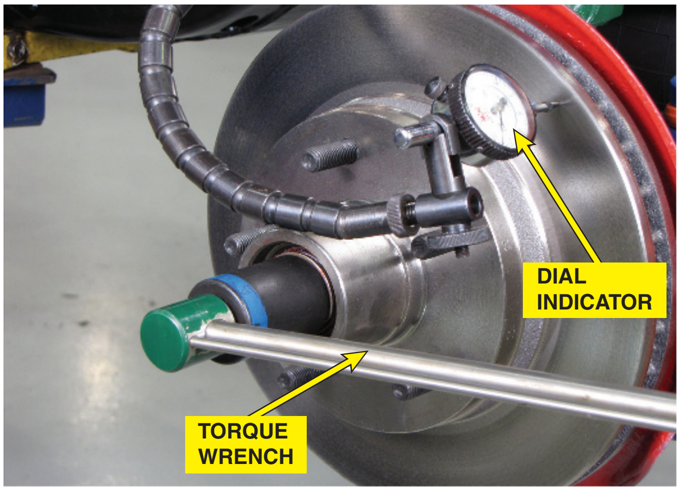

FIGURE 103–27 Before measuring lateral runout with a dial indicator (gauge), remove any wheel bearing end play by tightening the spindle nut to 10 to 20 ft-lb with a torque wrench. This step helps prevent an inaccurate reading. If the vehicle is to be returned to service, be sure to loosen the spindle nut and retighten to specifications (usually, finger tight) to restore proper bearing clearance.

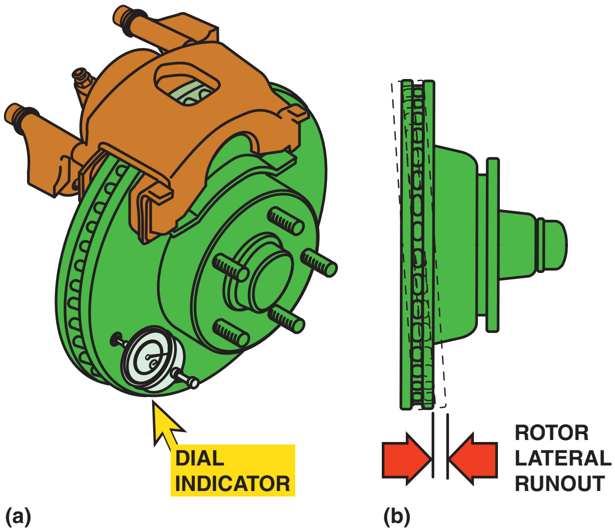

FIGURE 103–28 (a) Rotate the disc brake rotor one complete revolution while observing the dial indicator (gauge). (b) Most vehicle manufacturers specify a maximum runout of about 0.003 inch (0.08 mm).

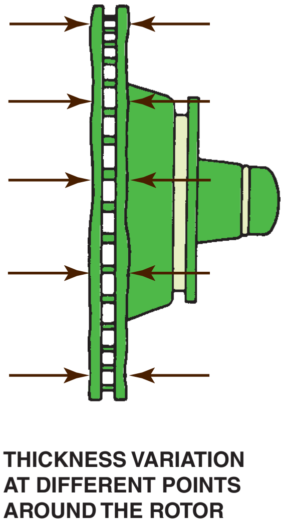

FIGURE 103–29 Brake rotor lack-of-parallelism distortion. A variation in the thickness of the rotor, commonly called **disc thickness variation (DTV)** can cause brake pedal pulsation during braking.

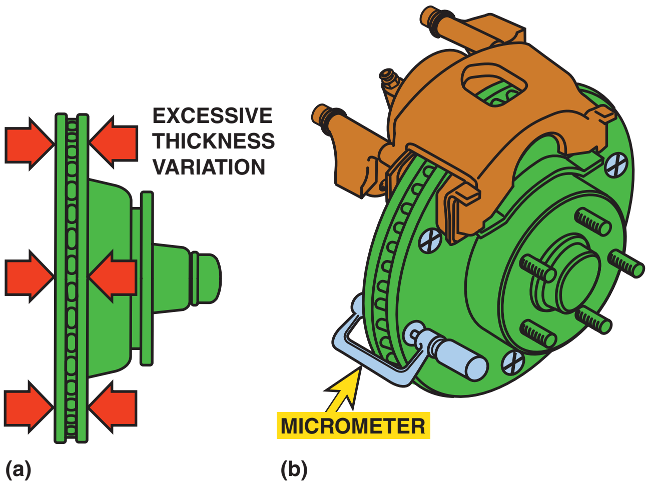

FIGURE 103–30 (a) Disc brake rotor thickness variation (parallelism). (b) The rotor should be measured with a micrometer at four or more equally spaced locations around the rotor.

TECH TIP

Braking Vibration Could Be Due to the Tires

A vibrating condition (roughness) during braking is usually caused by disc brake rotor thickness variation or an out-of-round brake drum. Both conditions should be investigated. However, the tires and/or road conditions can also cause the same vibrations.

Tests performed by vehicle and tire-manufacturing engineers have shown that tires, and tires alone, could be the cause. If no other problem can be isolated, install a different brand of tire on the vehicle and retest. The cause of the tire vibration seems to be due to distortion or movement of the tire tread. A different brand of tires would have a different tread rubber compound, carcass body ply angles, or other factor that can contribute to a vibration during braking.

TECH TIP

Think of a Human Hair

Measurements and specifications do not seem to mean much unless you can visualize the size compared to something with which you are familiar. The diameter of a human hair is from 0.002 to 0.004 inch (2 to 4 thousandths of an inch).

The maximum lateral runout of a rotor is usually within this same dimension. The reason a dial indicator has to be used to measure runout, and a micrometer to measure parallelism, is that the dimensions involved are less than the diameter of a human hair.

rest of the rotor, and because the rusted areas wear faster, this results in a thickness variation when the vehicle is driven again.

Because parallelism variation is much more likely to cause a problem than lateral runout, the maximum amount allowed is much smaller than for runout. Most manufacturers specify that the two friction surfaces of a rotor must be parallel within half a thousandth of an inch, 0.0005 inch (0.013 mm), or less.

CARBON-CERAMIC ROTORS

DESCRIPTION Carbon-ceramic brake (CCB) rotors are used on some high-performance vehicles and are very expensive. Carbon-ceramic rotors are used as standard or optional equipment on vehicles such as Aston Martin, Audi, Bentley, Bugatti, Ferrari, Lamborghini, Mercedes-Benz, and Porsche as well as on the 2009+ Corvette ZR1.

CONSTRUCTION Carbon-ceramic brake rotors are made of a carbon-fiber-reinforced ceramic silicon carbide material. The main ingredient is silicon carbide, which provides the hardness, and the other major ingredient, carbon fiber, provides the strength to the rotors. When the rotors are made, carbon fibers are blended with a resin that has carbon and silicon. The mixture is pressed into a mold to form the rotor and then heated to about 3,000°F (1,650°C) which converts the resin to silicon carbide, which is the "ceramic" in the carbon-ceramic rotor.

ADVANTAGES The advantages of carbon-ceramic brake rotors include the following:

- **Low weight**—This improves vehicle performance and handling.
- **Corrosion and wear resistant**—This means that the rotors should not need to be replaced during the life of the vehicle.

SERVICE PROCEDURES Carbon-ceramic brake rotors cannot be machined or serviced. The brake pads used with carbon-ceramic rotors are special and any other pads other than the specified brake pad should be used.

During service, if needed, the rotor is weighed and if under the minimum specified weight, must be replaced. ● **SEE FIGURE 103–31**.

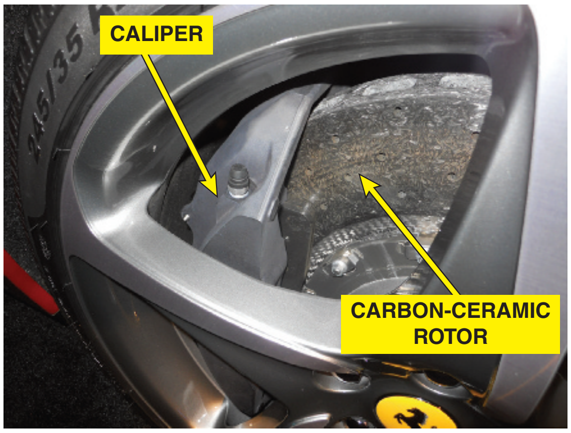

FIGURE 103–31 A carbon-ceramic brake (CCB) rotor on a Ferrari.

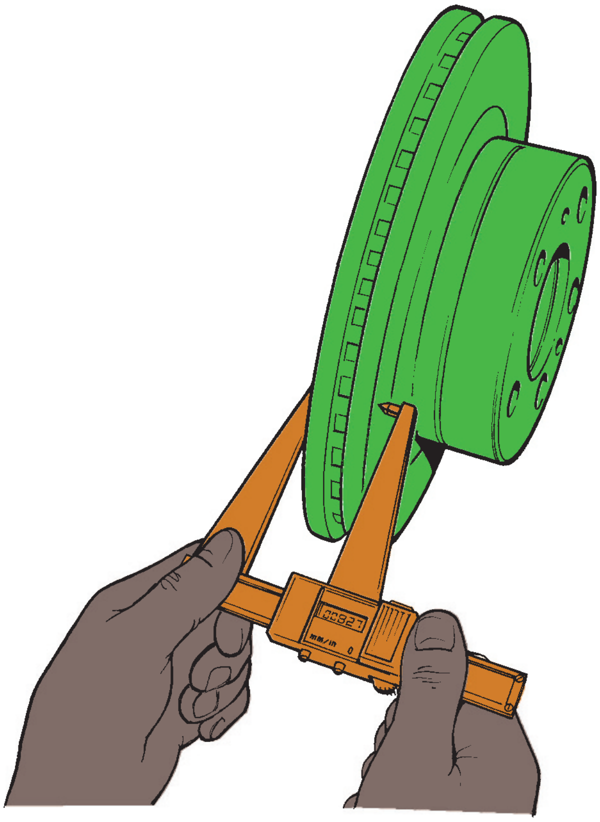

FIGURE 103–32 A digital readout rotor micrometer is an accurate tool to use when measuring a rotor. Both fractional inches and metric millimeters are generally available.

Check service information for the specified procedure to follow for removing the disc brake rotor. Inspect and clean the rotor mounting surface (hub) to make sure that it is clean and flat.

DISC BRAKE ROTOR THICKNESS

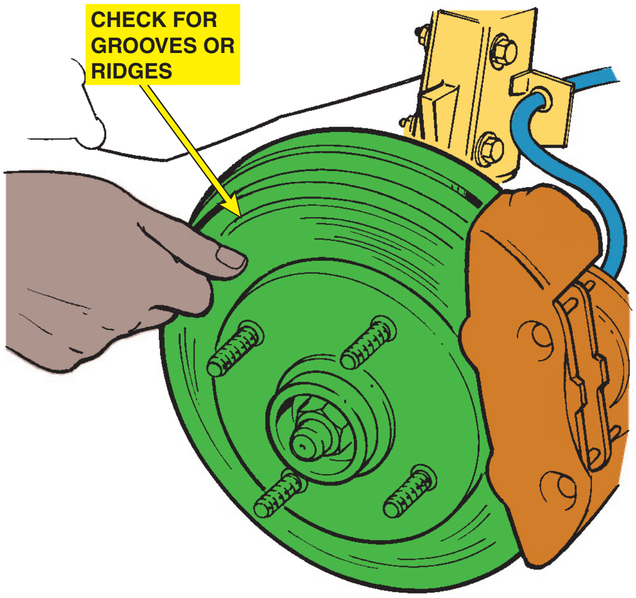
Most rotors have a minimum thickness cast or stamped into the rotor. This thickness is minimum wear thickness. At least 0.015 inch (0.4 mm) must remain after machining to allow for wear. Some vehicle manufacturers, such as General Motors, specify that 0.030 inch (0.8 mm) be left for wear. ● **SEE FIGURE 103–32**.

Whenever machining (resurfacing) a rotor, an equal amount of material must be removed from each side.

WHEN THE ROTORS SHOULD BE MACHINED

According to brake design engineers, a worn rotor has a very smooth friction surface that is ideal for replacement (new) disc brake pads. Often when the rotors are machined, the surface finish is not as smooth as specified. Therefore, a rotor should be machined only if one of the following conditions exists:

1. Grooves deeper than 0.060 inch (1.5 mm). This is the approximate thickness of a nickel. ● **SEE FIGURE 103–33**.



CHECK FOR GROOVES OR RIDGES

FIGURE 103–33 If a fingernail catches on a groove in the rotor, the rotor should be machined.

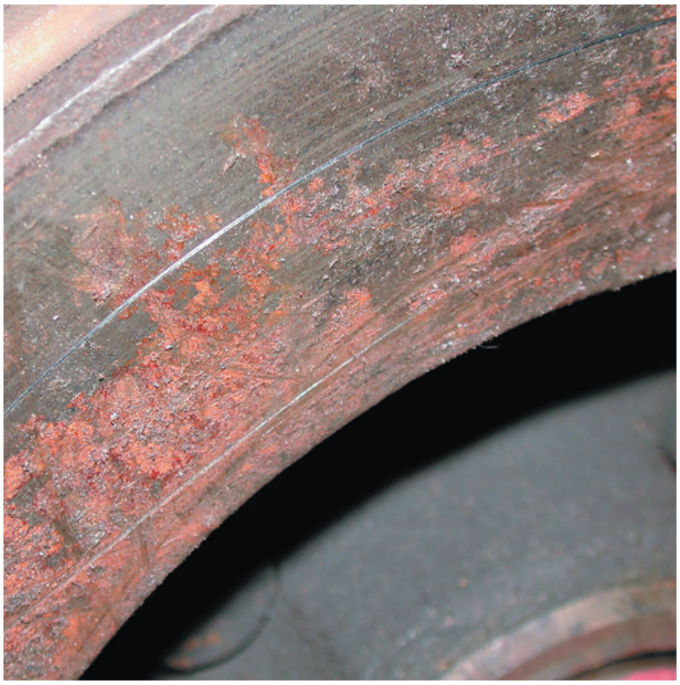


FIGURE 103–34 This rusted rotor should be machined.

2. Thickness variation exceeding specifications and a brake pedal pulsation complaint.
3. Heavy rust that has corroded the friction surface of the rotor. ● **SEE FIGURES 103–34 AND 103–35**.

Therefore, if there is no complaint of a pulsating brake pedal during braking and the rotor is not deeply grooved or rusted, it should not be machined. New disc brake pads perform best against a smooth surface, and a used disc brake rotor is often smoother than a new rotor.

ROTOR FINISH

The smoothness of the rotor is called rotor finish or surface finish. Surface finish is measured in units called **microinches**, abbreviated **μin.**, where the symbol in front of "in."

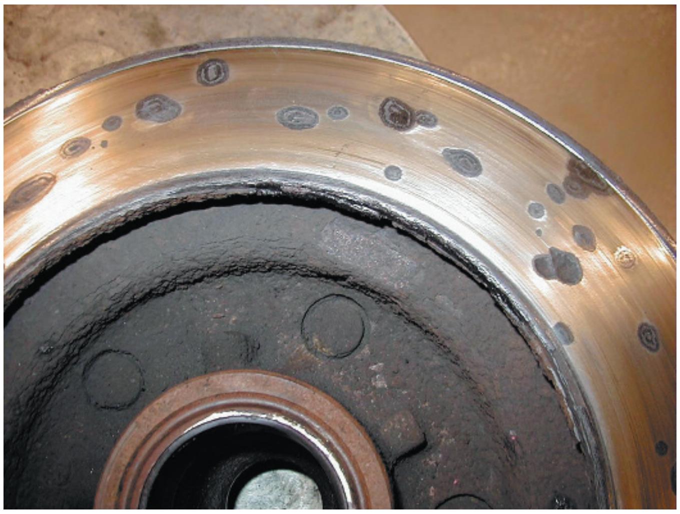

FIGURE 103–35 Rotors that have deep rust pockets usually cannot be machined.

is the Greek lowercase letter μ (mu). One microinch equals 0.000001 inch (0.025 micrometer [μm]). The finish classification of microinch means the distance between the highest peaks and the deepest valley. The usual method of expressing surface finish is the arithmetic average roughness height (AARH), **Ra**, which is the average of all peaks and valleys from the mean (average) line. This surface finish is measured using a machine with a diamond stylus, as shown in ● **FIGURE 103–36**.

Another classification of surface finish that is becoming obsolete is the *root mean square* (RMS). The RMS method gives a slightly higher number and can be obtained by multiplying Ra × 1.11 = RMS.

Often, a machined rotor will not be as smooth as a new rotor, resulting in a hard-stopping complaint after new brakes have been installed. A rough rotor has less surface area touching the new brake pads, resulting in a hard brake pedal and reduced braking effectiveness. Most new rotors have a surface finish of 45 to 60 μin. Ra.

- The higher the Ra of a rotor, the rougher the surface finish.
- The lower the Ra number, the smoother the surface finish.

TECH TIP

The Ballpoint Pen Test

A smooth friction surface on a drum or rotor is necessary for proper brake operation. To quickly determine if the friction surface of a brake drum or rotor is not smooth enough, draw a ballpoint pen across the surface. If the surface is smooth enough, a solid ink line will be observed. If the line drawn by the pen is not solid, then the surface is not smooth enough.

QUALIFYING A BRAKE LATHE

PURPOSE OF QUALIFYING A BRAKE LATHE All brake lathes should be checked regularly to make sure that they are in good condition and are capable of machining brake drums and rotors accurately.

QUALIFYING PROCEDURE To qualify a brake lathe, use the following generic checklist.

STEP 1 Check for proper operation of all motors, switches, and feed controls. Check that the engage and disengage levers function properly.

STEP 2 Make sure radius cones, bell clamps, and taper cones are free of all nicks, burrs, rust, and foreign debris. To restore flatness, use an 80-grit silicon carbide hone and WD-40 lubricant. Apply light pressure using short figure-eight movements to prevent rounding of the edges.

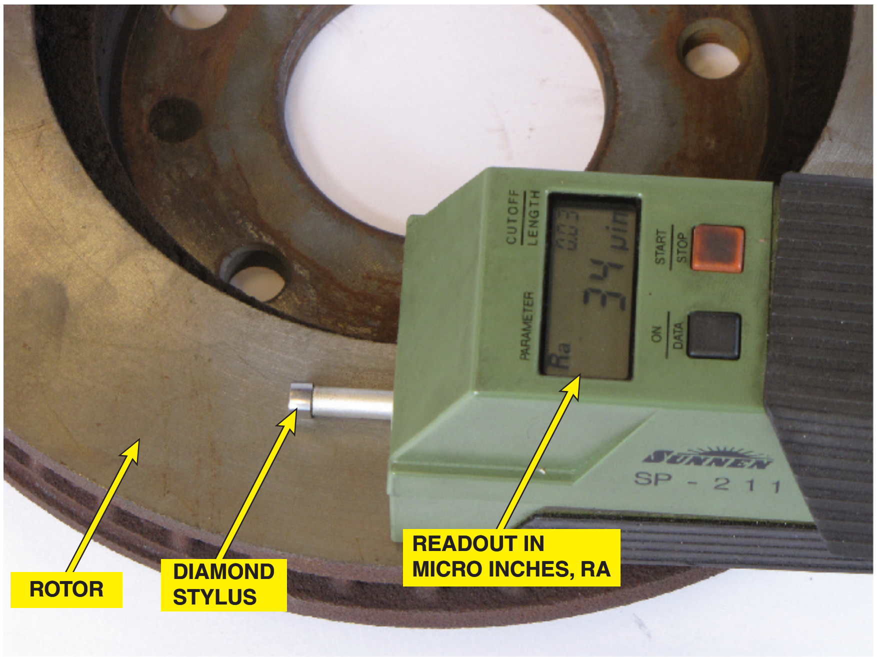

FIGURE 103–36 Electronic surface finish machine. The reading shows about 34 μin. This is a very smooth rotor and is suitable for use with any brake pad.

STEP 3 Check the tapered surfaces on the arbor and spindle to ensure these surfaces are totally free of any contamination. The arbor run out should not be over two thousandths of an inch (0.002") total indicator runout (TIR). ● **SEE FIGURE 103–37**.

STEP 4 The shoulder of the arbor must also be free of nicks or debris. Spray the shoulder of the arbor with WD-40 and use the arbor shaft for a guide to hold the hone perpendicular to the shoulder. Turn the lathe on and hone the shoulder. Apply pressure on the hone with a finger on the arbor.

STEP 5 Check fit of the rotor truer and the top of the dovetail way. A one thousandths feeler gauge should not be able to fit between the top dovetail surface and the bottom of the rotor. Remove the rotor truer and hone the top dovetail surface and the bottom of the rotor truer until the feeler gauge stock cannot be inserted.

STEP 6 The tool bit holder slots on the rotor truer should be clean. Make sure the bottom of the tool bit holder is also clean. The tool bit holder bottom can be cleaned by rubbing it on a hone or a single cut file. The carbide bit seat on the tool bit holder should be clean and flat. If the surface is not flat, replace the tool bit holder.

STEP 7 All end bell clamps can be remachined to reduce runout. Mount the bell clamp with the machined hub mating with the shoulder of the arbor. Use the two small radius adapters next on the arbor and space out to the threads with available radius adapters or one inch spacer.

Tighten the arbor nut. Put a reference mark on the bell clamp that lines up with the two marks on the spindle and arbor. Machine the face of the bell clamp with the rotor truer. True all four bell clamps.

STEP 8 Always align the inside bell clamp with the reference mark put on the hub after machining the bell clamp. Keep all mounting surfaces clean and occasionally check accuracy of setup by holding the inside bell clamp and rotating the rotor 180 degrees. Reclamp and check with the dial indicator. If runout is excessive, hone the adapter. If runout persists, remachine the adapter.

STEP 9 The inside of the hat section of the rotor must be cleaned of all rust, burrs, and any foreign matter. If any debris is present on this surface, the rotor will not reference properly while machining.

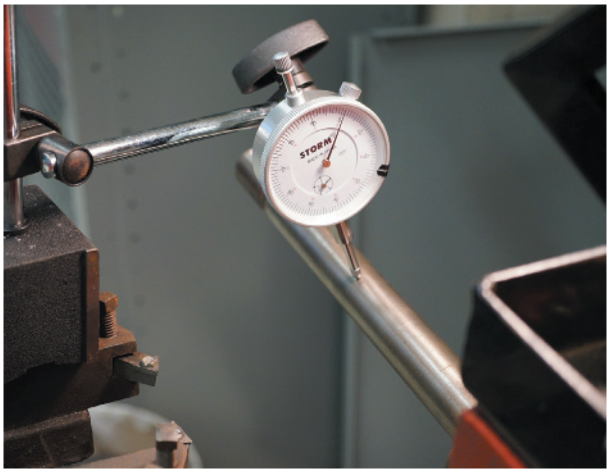

FIGURE 103–37 A dial indicator being used to check the arbor for total indicator runout (TIR) in a brake lathe.

STEP 10 All surfaces of the lathe, arbor, and all of the adapter surfaces must be free of nicks, burrs, and foreign debris.

NOTE: Always follow the lathe manufacturer's specific operating and maintenance instructions.

MACHINING A DISC BRAKE ROTOR

Before machining a rotor, be sure that it can be machined by comparing the minimum thickness specification and the measured thickness of the rotor. Many lathes are capable of removing a large amount of material in one pass, thereby reducing the time necessary to refinish a rotor. These lathes usually use a positive rake tool bit angle. ● **SEE FIGURE 103–38**.

Other lathes that use six-sided reversible tool bits usually use a negative rake tool bit angle. Ammco is an example of a negative rake lathe, whereas Perfect-Hofmann and Accu-turn are examples of positive rake lathes.

CAUTION: Some original equipment and replacement disc brake rotors are close to the minimum allowable thickness when new. Often, these rotors cannot be safely machined at all.

Following is an example of the steps necessary to machine a disc brake rotor. Always follow the instructions for the equipment you are using.

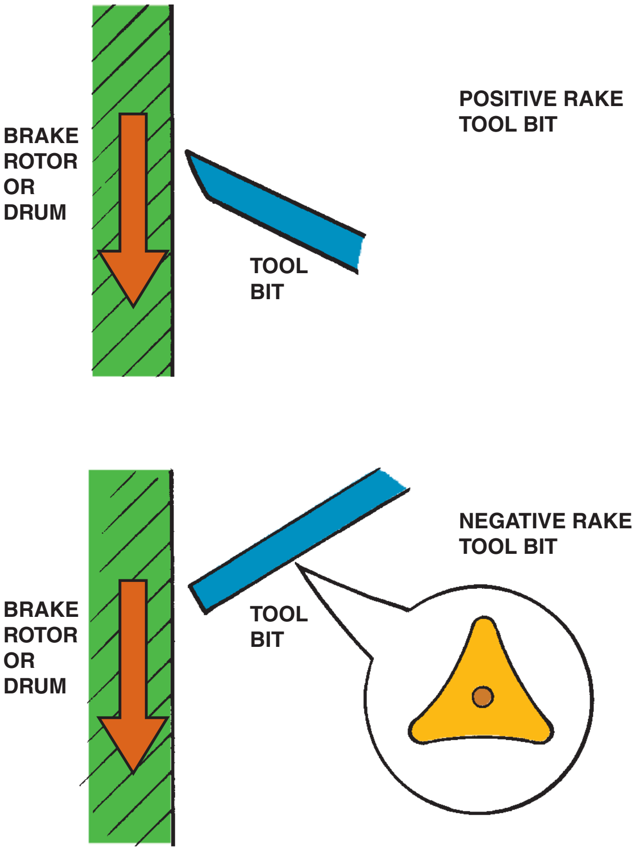

FIGURE 103–38 Most positive rake brake lathes can cut any depth in one pass, thereby saving time. A typical negative rake lathe uses a three-sided turning tool that can be flipped over, thereby giving six cutting edges.

1. Mount the disc brake rotor to the spindle of the lathe using the cones and adapters recommended. ● **SEE FIGURES 103–39 AND 103–40**.
2. Install a rotor damper and position the cutting tools close to the rotor surface, as shown in ● **FIGURE 103–41**.

NOTE: Failure to install the damper causes vibrations to occur during machining that creates a rough surface finish.

3. Make a scratch cut on the rotor face, as shown in ● **FIGURE 103–42**.
4. To check that the rotor is mounted correctly, loosen the retaining nut, turn the rotor one-half turn (180 degrees), and retighten the nut. Make another scratch cut.
   a. The second scratch cut should be side-by-side with the first scratch cut if the rotor is properly installed, as shown in ● **FIGURE 103–43**.

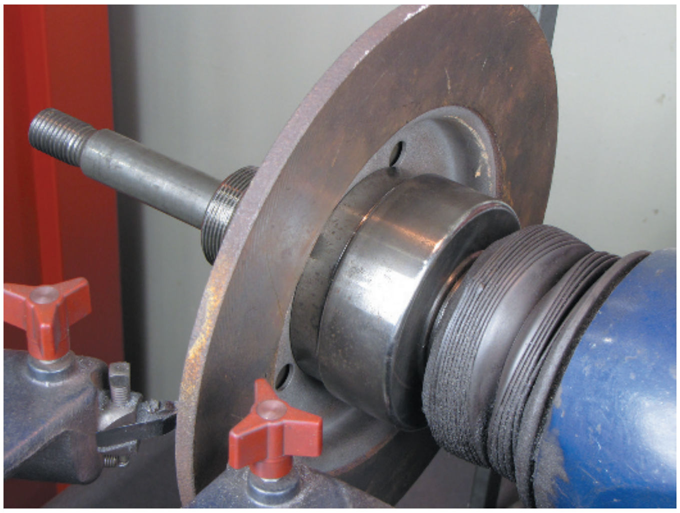

FIGURE 103–40 A composite rotor properly mounted on a brake lathe.

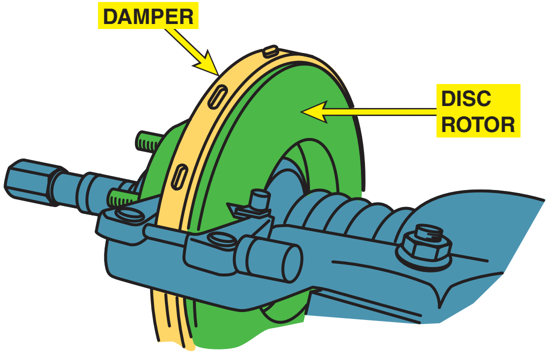

FIGURE 103–41 A damper is necessary to reduce cutting-tool vibrations that can cause a rough surface finish.

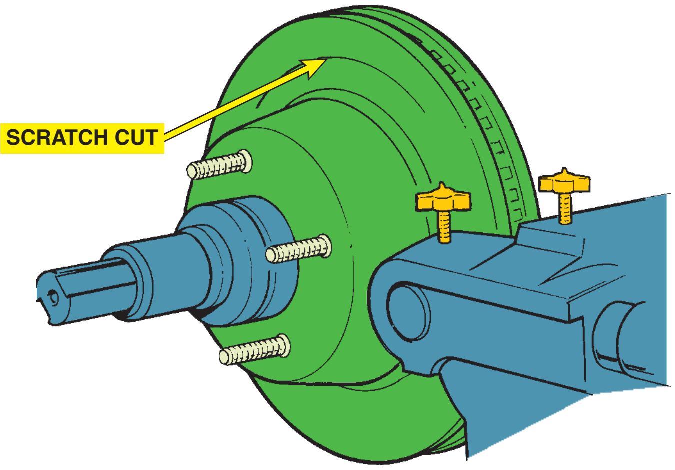

FIGURE 103–42 After installing the rotor on the brake lathe, turn the cutting tool in just enough to make a scratch cut.

b. If the second scratch cut is on the opposite side (180 degrees) from the first scratch cut, the rotor may not be installed on the lathe correctly.

NOTE: The runout as measured with a dial indicator on the brake lathe should be the same as the runout measured on the vehicle. If the runout is not the same, the rotor is not installed on the brake lathe correctly.

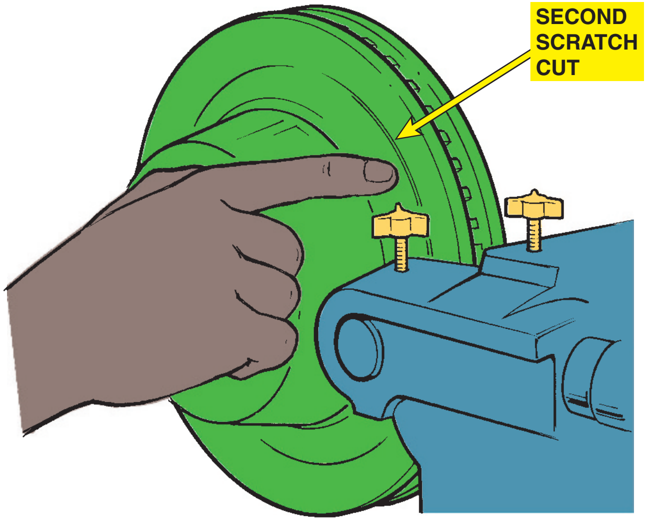

FIGURE 103–43 After making a scratch cut, loosen the retaining nut and rotate the rotor on the spindle of the lathe one-half turn. Tighten the nut and make a second scratch cut. The second scratch cut should be side-by-side with the first scratch if the rotor is installed correctly on the brake lathe.

After proper installation of the disc brake rotor on the brake lathe, proceed with machining the rotors. For best results, do not machine any more material from the rotor than is absolutely necessary. Always follow the recommendations and guidelines as specified by the vehicle manufacturer.

ROUGH CUT A rough cut on a lathe involves cutting 0.005 inch per side with a feed of 0.008 inch per revolution and 150 RPM spindle speed. This usually results in a very coarse surface finish of about 150 μin. Ra.

FINISH CUT A finish cut means removing 0.002 inch per side with a feed of 0.002 inch per revolution and 150 RPM spindle speed. Although this cut usually looks smooth, the surface finish is about 90 to 100 μin. Ra. Even a typical finish cut is still not nearly as smooth as a new rotor.

NOTE: Measure the thickness of the rotor after the finish cut and compare with manufacturer's specifications. Be sure to allow for wear. ● SEE CHART 103–1 for a metric/fractional measurement chart.

NONDIRECTIONAL FINISH Most vehicle and brake component manufacturers recommend a nondirectional finish to help prevent the grooves machined into the rotor from acting like record grooves that can force the pads to move outward while the rotor rotates.

CAUTION: Some nondirectional finish tools such as those that use Scotch Brite (a registered trademark) plastic pads often do not make the rotor as smooth as new, even though the finish has been swirled. ● SEE FIGURE 103–44.

SURFACE FINISHING THE ROTOR The goal of any brake repair or service should be to restore the braking effectiveness to match new vehicle brakes. This means that the rotor finish should be as smooth or smoother than a new rotor for

maximum brake pad contact. Research conducted at Delphi has shown that like-new rotor finish can easily be accomplished by using a block and sandpaper. After completing the finish cut, place 150-grit aluminum-oxide sandpaper on a block and apply steady pressure against the rotor surface for 60 seconds on each side of the rotor. ● **SEE FIGURE 103–45**.

The aluminum oxide is hard enough to remove the highest ridges left by the lathe cutting tool. This results in a surface finish ranging from 20 to 80 μin. and usually less than 40 μin., which is smoother than a new rotor. ● **SEE FIGURE 103–46**.

NOTE: Many commercial rotor-finish products may also give as smooth a surface finish. ● SEE FIGURES 103–47 AND 103–48.

Always compare rotor finish to the rotor finish of a new rotor. Microinch finish is often hard to distinguish unless you have a new rotor with which to compare.

ON-THE-VEHICLE ROTOR MACHINING

Many vehicle manufacturers recommend on-the-vehicle machining for rotors if the disc brake rotor must be machined due to deep scoring or pulsating brake pedal complaint. This is especially true of composite rotors or for vehicles, such as many Honda vehicles, that require major disassembly to remove the rotors.

Caliper-mount, on-the-vehicle lathes require that the disc brake caliper be removed. The cutter attaches to the steering knuckle or caliper support in the same location as the caliper. ● **SEE FIGURE 103–49**. Hub-mount, on-the-vehicle lathes attach to the hub using the lug nuts of the vehicle. To achieve a proper cut, the hub mount must be calibrated for any runout caused by the hub bearings and the outside surface face of the rotor.

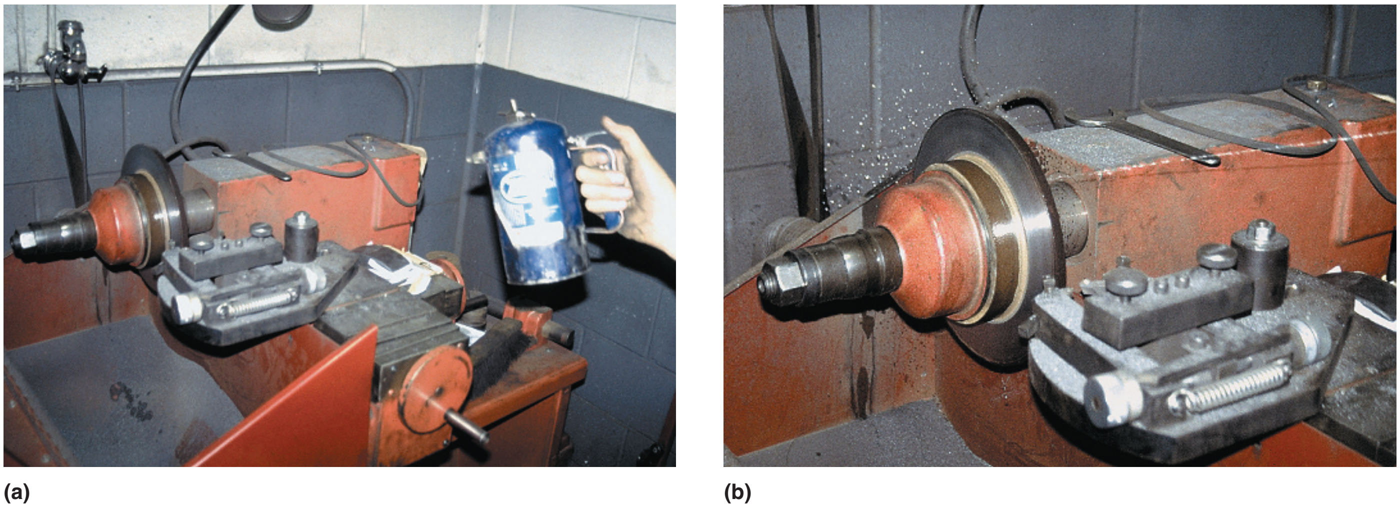
FIGURE 103–44 (a) This technician uses two sanding blocks each equipped with 150-grit aluminum-oxide sandpaper. (b) With the lathe turned on, the technician presses the two sanding blocks against the surface of the rotor after the rotor has been machined to achieve a smooth microinch surface finish. Most experts recommend washing the rotor with soap and water to remove the grit from the sanding operation from the fine grooves in the rotor before they are installed on the vehicle.



(a)

(b)

FIGURE 103–45 (a) After machining and sanding the rotor, it should be cleaned. In this case, brake cleaner from an air pressurized spray can is used. (b) With the lathe turning, the technician stands back away from the rotor and sprays both sides of the rotor to clean it of any remaining grit from the sanding process. This last step ensures a clean, smooth surface for the disc brake pads and a quality brake repair. Sanding each side of the rotor surface for one minute using a sanding block and 150-grit aluminum-oxide sandpaper after a finish cut gives the rotor the proper smoothness and finish.

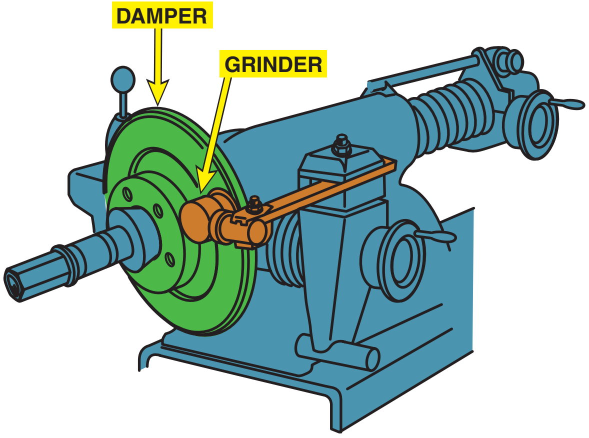


FIGURE 103–46 A grinder with sandpaper can be used to give a smooth nondirectional surface finish to the disc brake rotor.

Turn or Machine?

When asked about what was done to their vehicle, a common response of customers is "They rotated my rotors." Many customers do not understand the terms that are commonly used in the vehicle service industry. Try to use terms that are technically correct and avoid slang when talking to customers. For example, the expression *machined the rotors* indicates an operation, whereas the expression *turned the rotors* may be misinterpreted by some customers as simply meaning using your hand and moving (rotating) the rotor. *Resurfacing*, *refinishing*, and *reconditioning* are other terms that could be used to describe a drum or rotor machining operation.

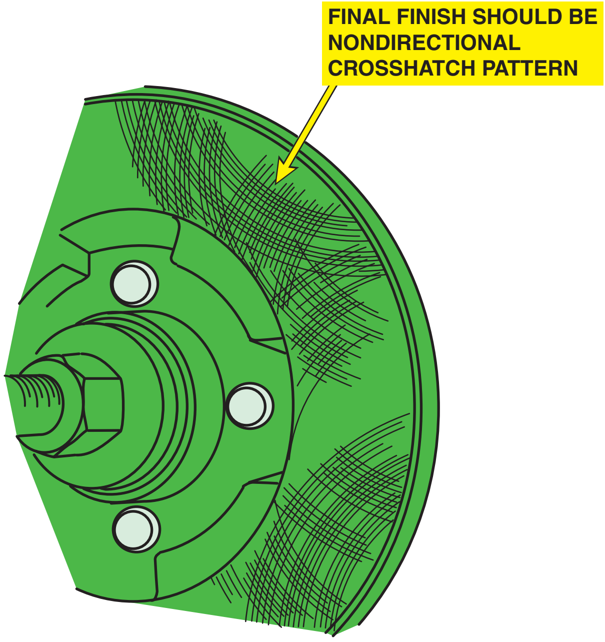

FIGURE 103–47 The correct final surface finish should be smooth and nondirectional.

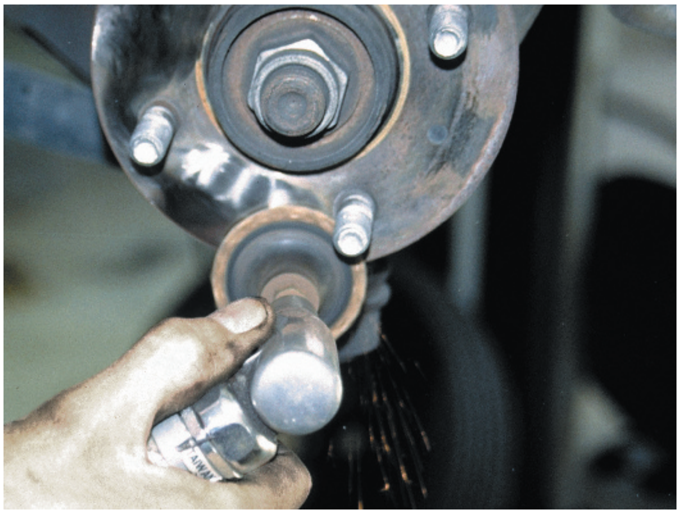

FIGURE 103–48 Rust should always be cleaned from both the rotor and the hub whenever the rotors are machined or replaced. An air-powered die grinder with a sanding disc makes quick work of cleaning this hub.

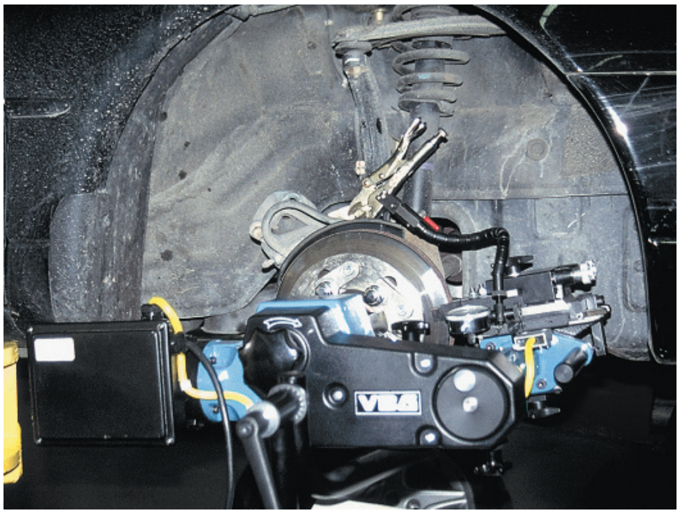

FIGURE 103–49 A typical hub-mount on-the-vehicle lathe. This particular lathe oscillates while machining the rotor, thereby providing a smooth and nondirectional finish at the same time.

NOTE: All on-the-vehicle lathes require that the wheel be removed. For best results, always use a torque wrench when tightening lug nuts or lathe adapters. Unequal torque on the bolts causes stress and distortion that can cause warped rotors and a pulsating brake pedal.

TECH TIP

Always Check the Wheel Studs

Before installing the wheel after brake service, check the condition of the wheel studs and lug nuts. Check for stripped threads, rust, or cracks. If necessary, replace the stud. Most studs are replaced by driving them out using a large hammer and then using washers and a lug nut to draw the serrated shoulder of the lug stud into the rotor stud hole. ● **SEE FIGURE 103–50**. Always use a torque wrench when installing lug nuts to ensure proper and even torque on all lug nuts. This helps to prevent rotor distortion, which can lead to vibration in the steering and/or pedal pulsation during braking.

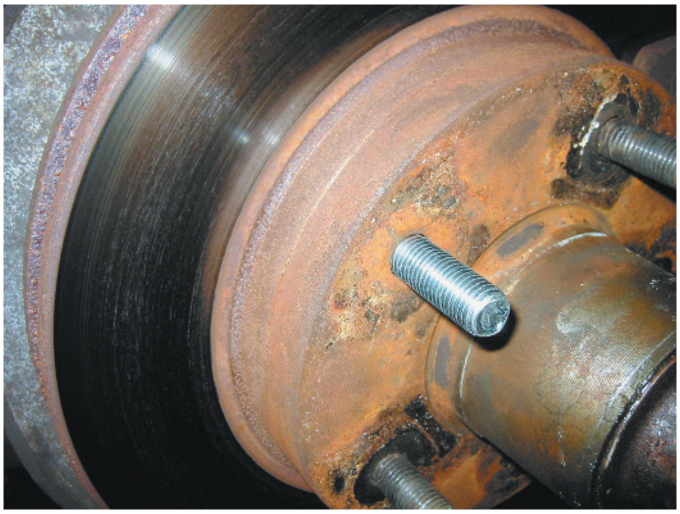

FIGURE 103–50 A wheel stud was replaced on the rotor hub assembly when it was discovered to be stripped.

DRUM MACHINING

STEP BY STEP

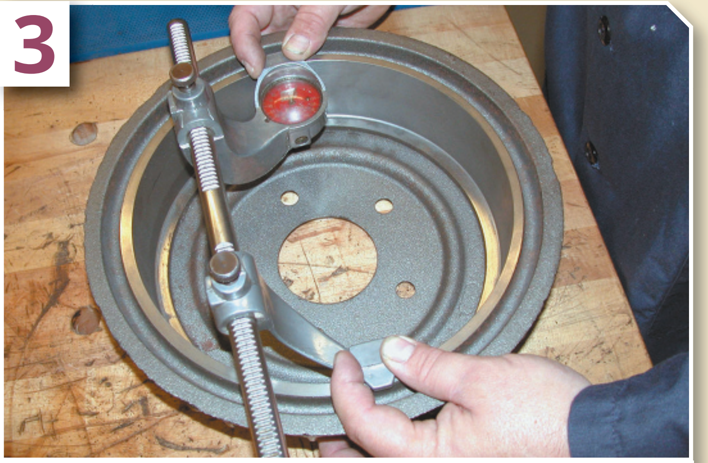
1

Before starting to machine a brake drum, check the drum for any obvious damage such as heat cracks or hard spots.

2

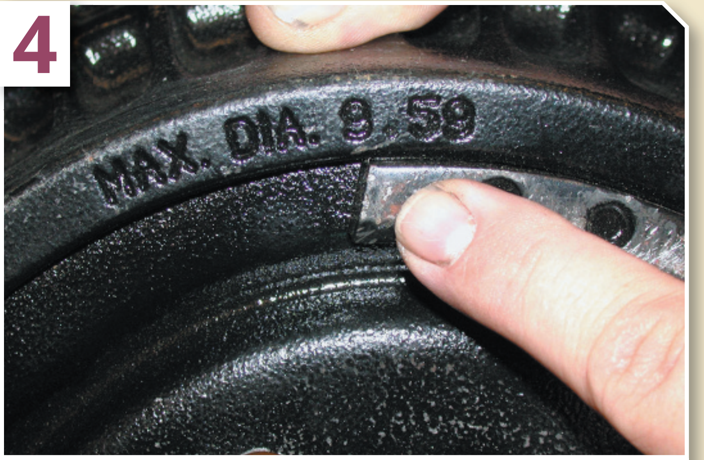
Lightly tap the drum. It should ring like a bell. If a dull thud is heard, the drum may be cracked and should be discarded.

3



Use a drum micrometer to measure the inside diameter of the drum and compare this measurement to specifications to be sure that the drum can be safely machined.

4



Most brake drums have the maximum inside diameter cast into the drum as shown.

5

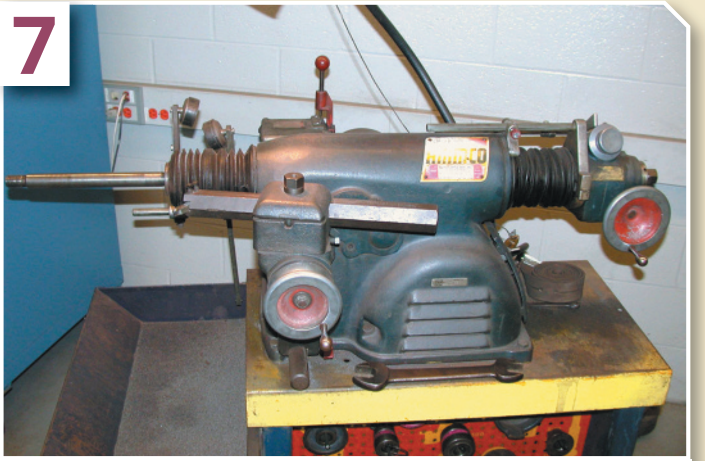
Thoroughly clean the outside and inside of the drum.

6

Be sure the center hole in the drum is clean and free from any burrs that could prevent the drum from being properly centered on the shaft of the brake lathe.

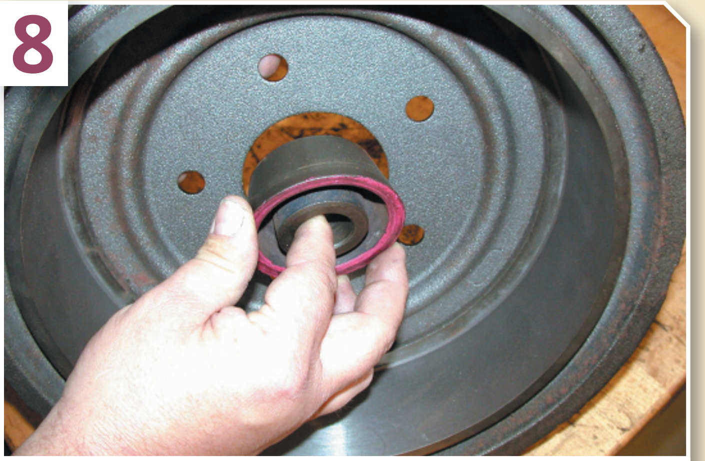
DRUM MACHINING

7



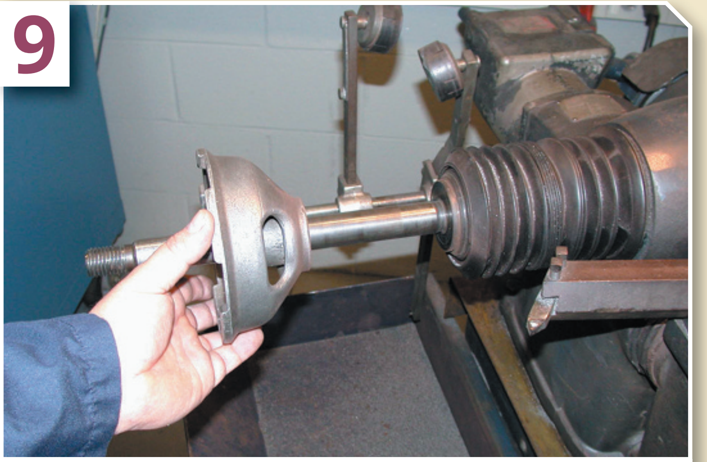
A typical brake lathe used to machine drums.

8



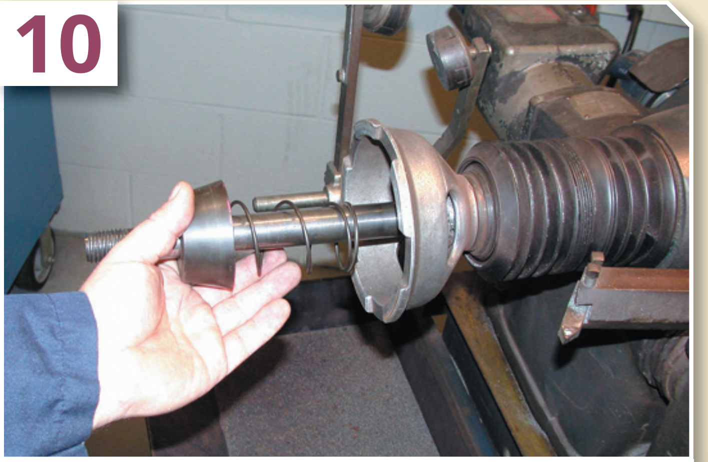
Locate a tapered, centering cone that best fits inside the hole of the brake drum.

9



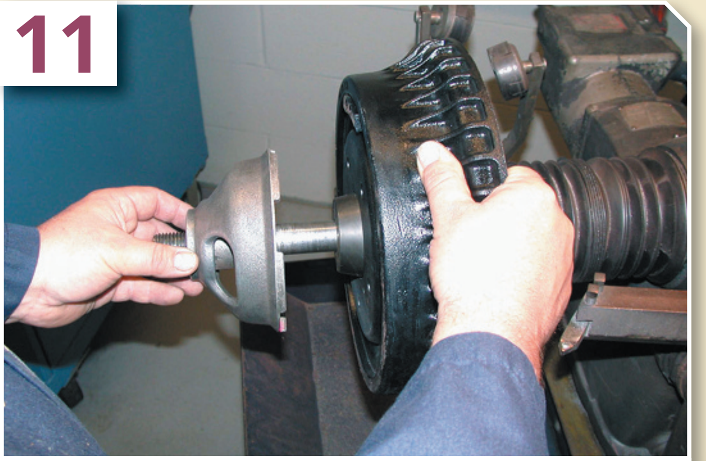
Slide the large face plate over the shaft of the brake lathe.

10



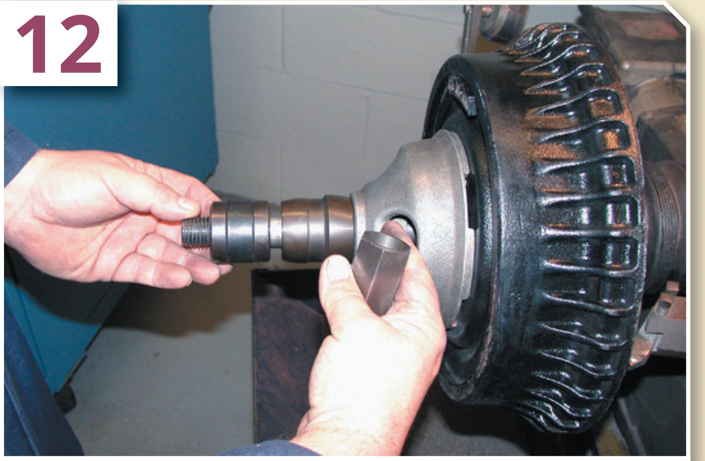
Slide the tapered centering cone onto the shaft with the spring between the face plate and the centering cone.

11



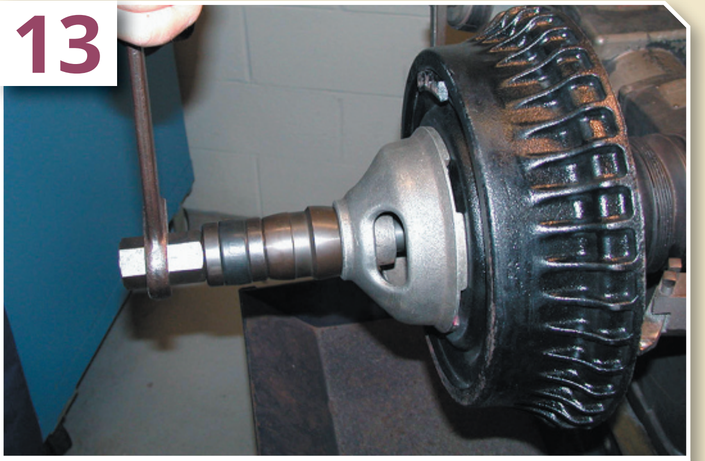
Slide the other face plate onto the shaft.

12



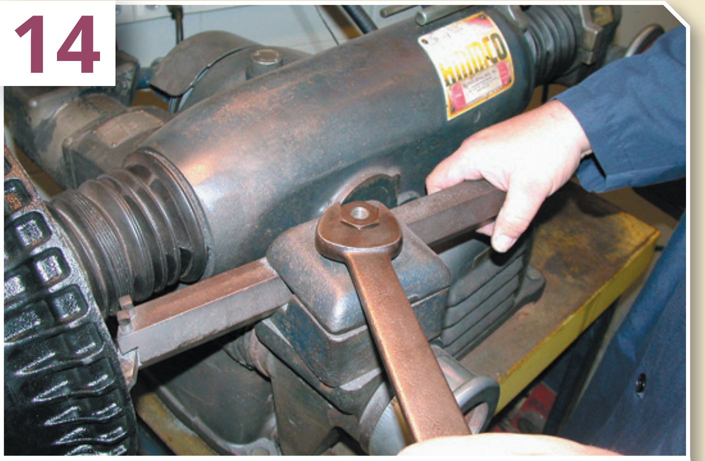
Install the self-aligning spacer (SAS) and left-hand-thread spindle nut.

13



Tighten the spindle nut.

14

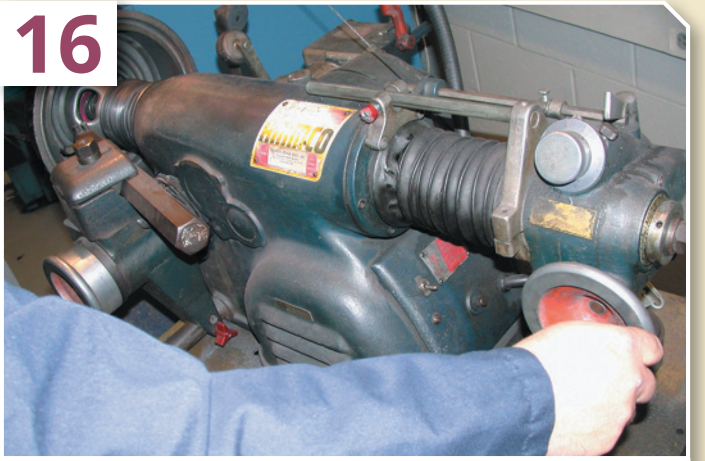


Loosen the turning bar retainer.

15

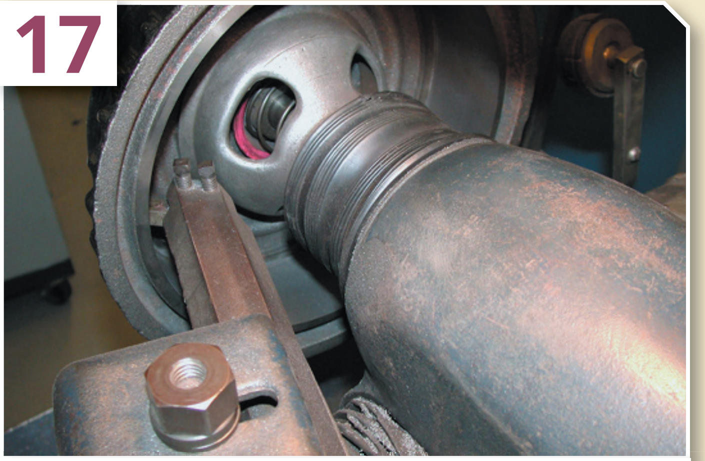
Carefully check the cutting bits and either rotate the bit to a new cutting point or replace it with a new part as necessary.

16



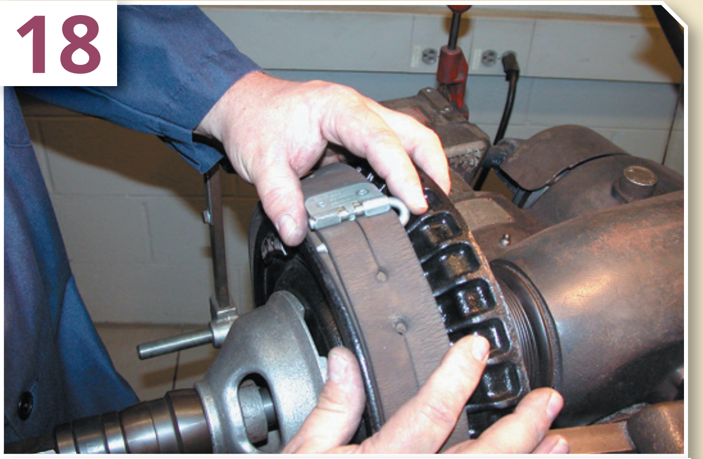
Turn the spindle control knob until the spindle is as short as possible (i.e., the drum as close to the machine as possible) to help reduce vibration as much as possible.

17



Position the cutting bar so that the cutting bit is located at the back surface of the drum.

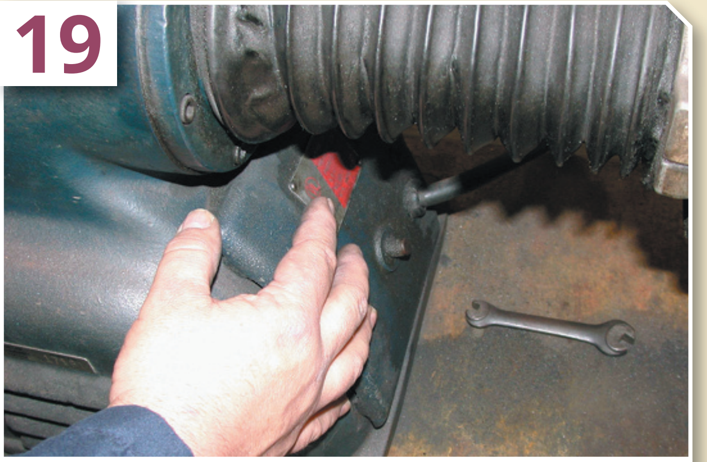
18



Install the silencer band (vibration dampener strap).

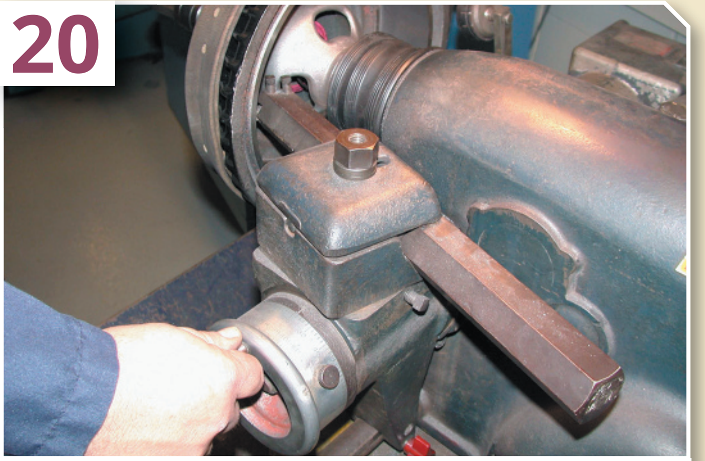
DRUM MACHINING

19



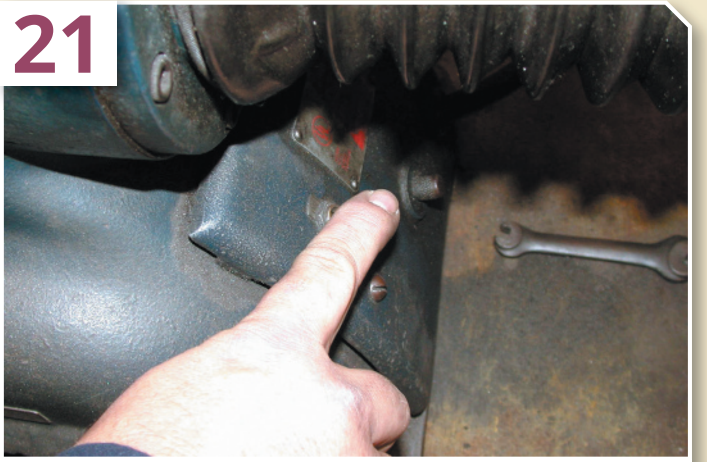
Be sure the tool bit and clothing are away from the drum and turn the brake lathe on.

20



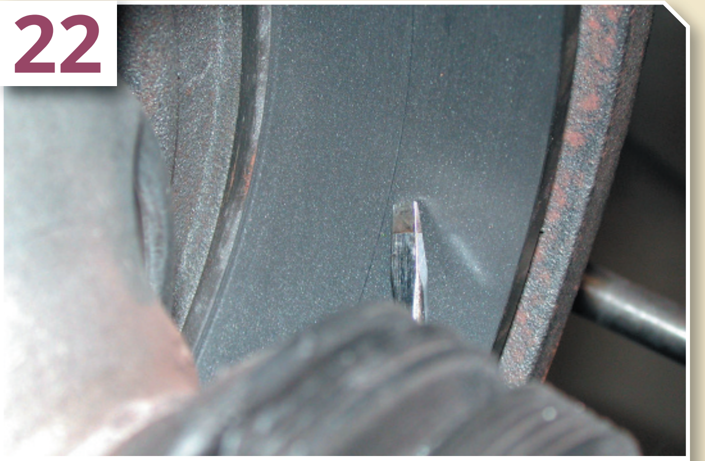
Center the bit in the center of the brake surface of the drum and rotate the control knob that moves the bit into contact with the drum friction surface. This should produce a light scratch cut.

21



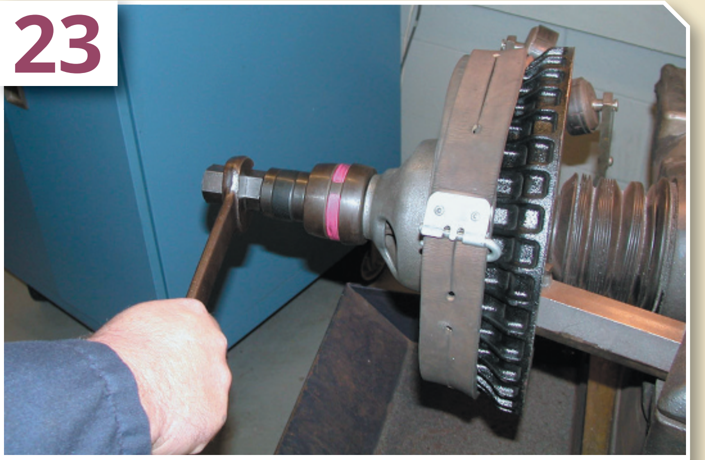
Turn the lathe off.

22



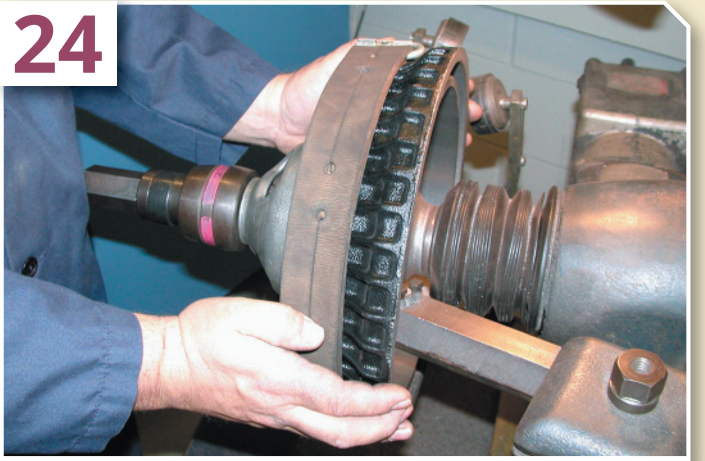
Observe the scratch cut.

23



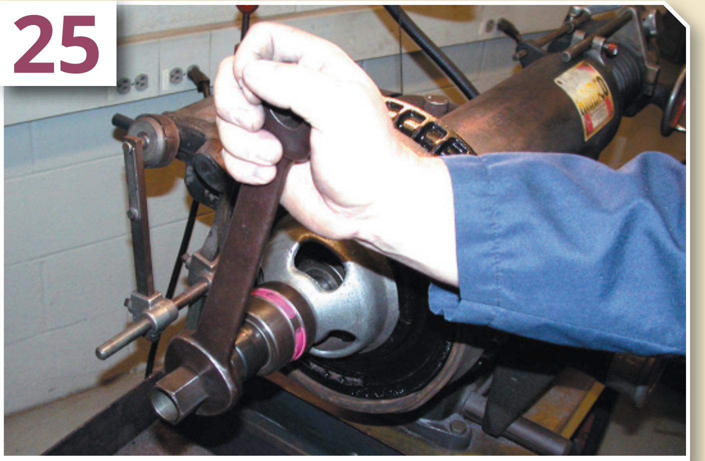
Loosen the spindle nut.

24



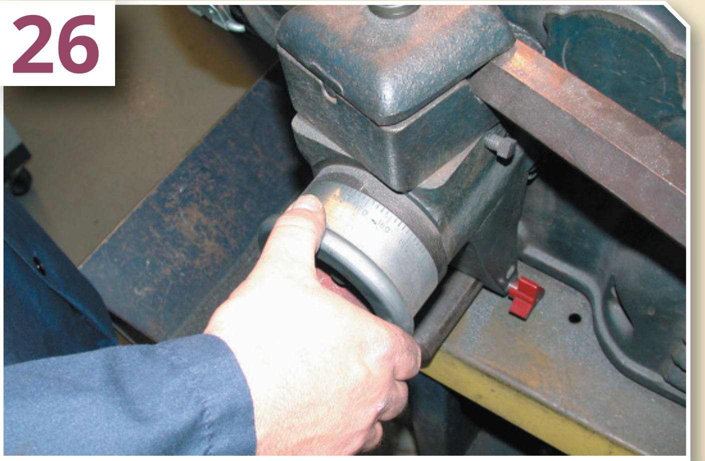
Rotate the drum 180 degrees (one-half turn) on the spindle.

25



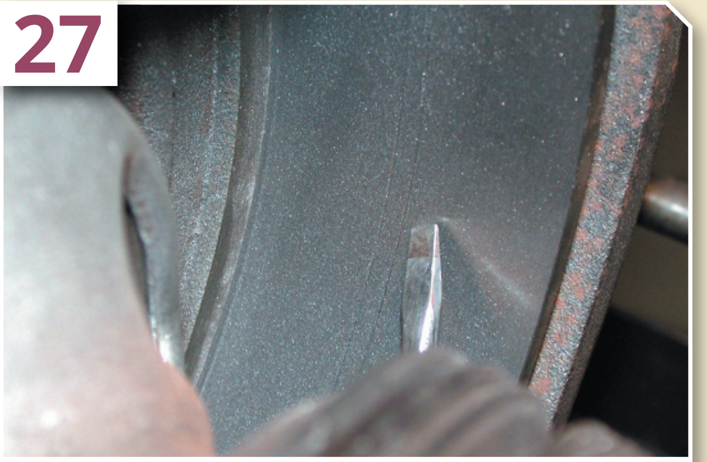
Tighten the spindle nut.

26



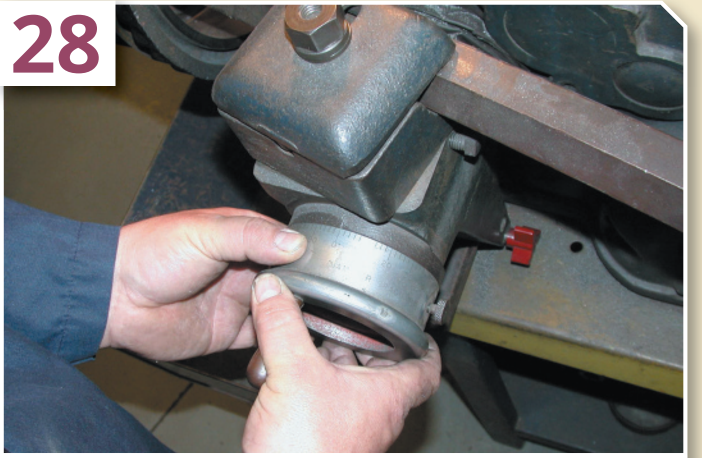
Turn the lathe on, rotate the control knob, and run the cutter into the drum for another scratch cut.

27



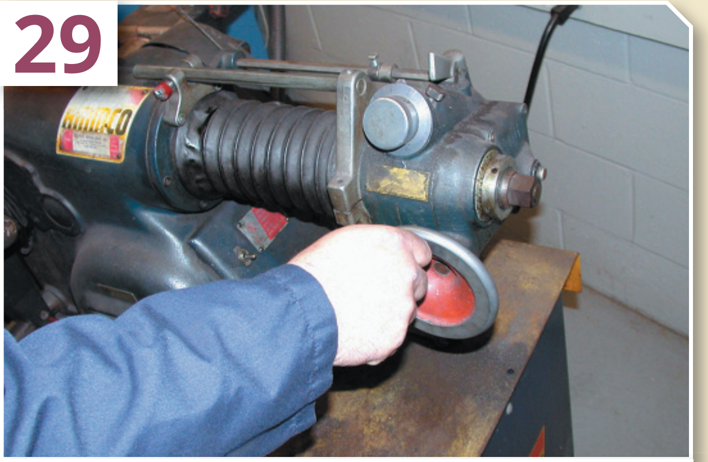
Observe the scratch cut. If the second scratch cut is in the same place as the first scratch cut or extends all the way around the drum, the drum is correctly mounted on the lathe.

28



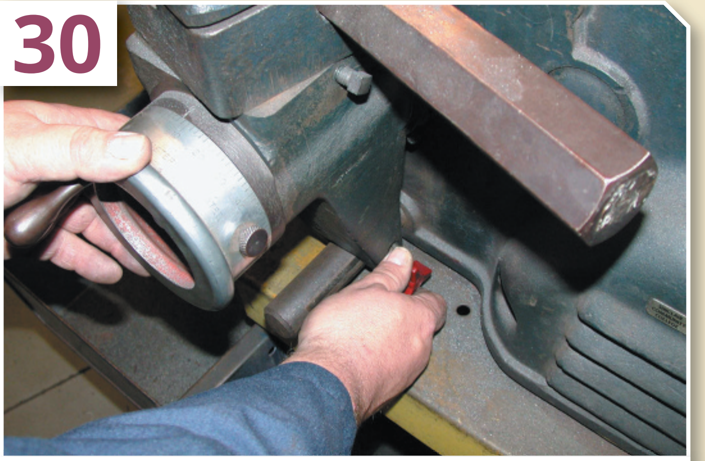
Adjust the depth gauge to zero when the cutter just touches the drum.

29



Run the cutter all the way to the back surface of the drum.

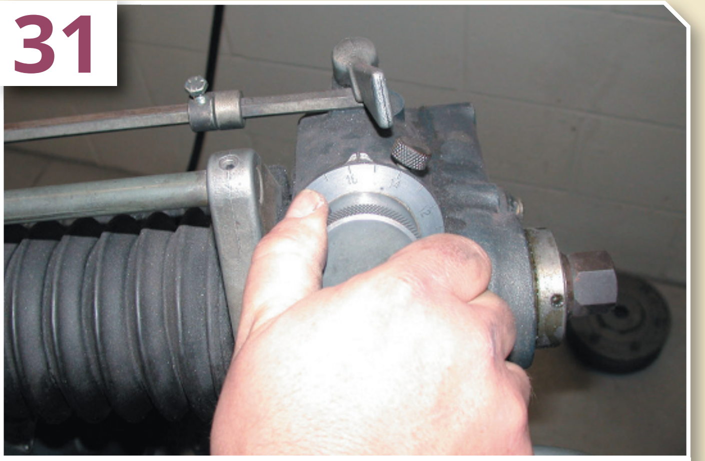
30



Adjust the depth of the cut and lock it in position by turning the lock knob. Most vehicle manufacturers recommend a rough cut depth should be 0.005–0.010 inch and a finish cut of 0.002 inch.

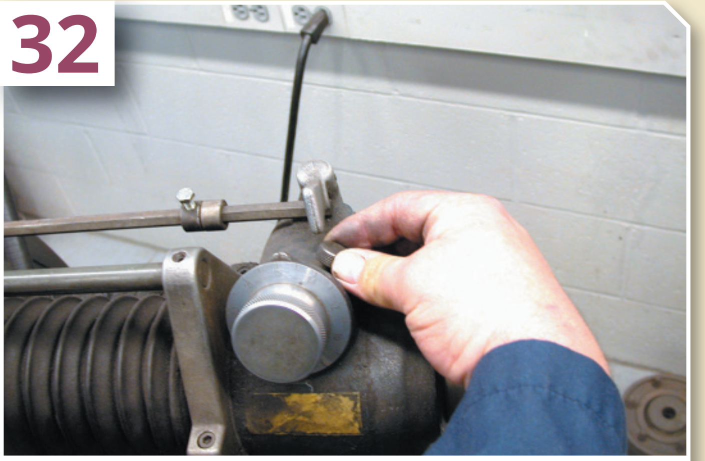
DRUM MACHINING

31



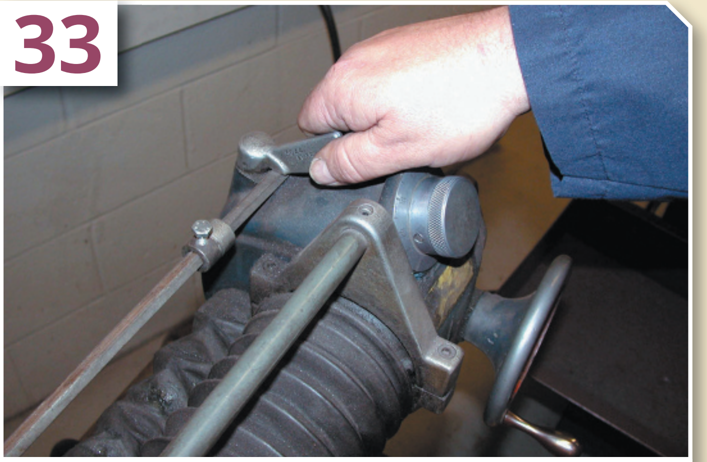
Select a fast-feed rate if performing a rough cut (0.006–0.016 in. per revolution) or 0.002 inch per revolution for a finish cut.

32



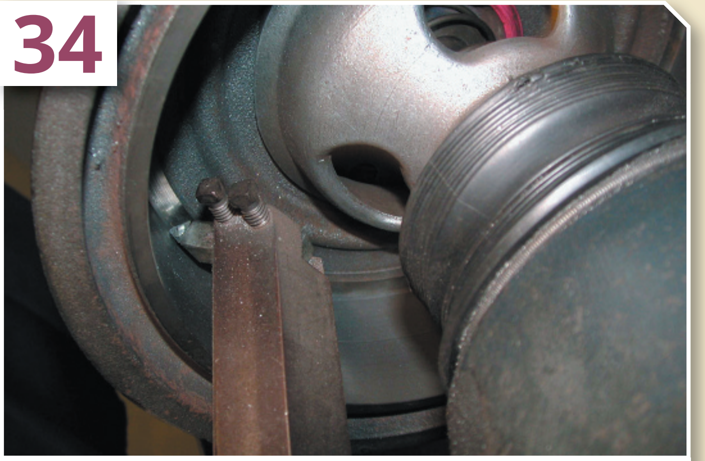
Turn the lock knob to keep the feed adjustment from changing.

33



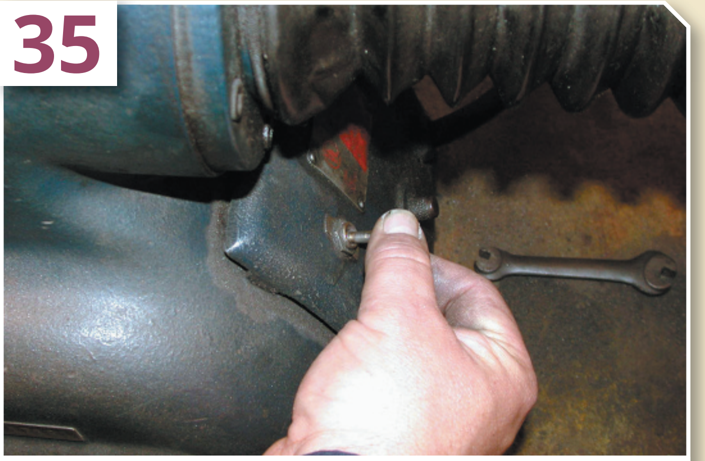
Engage the automatic feed.

34



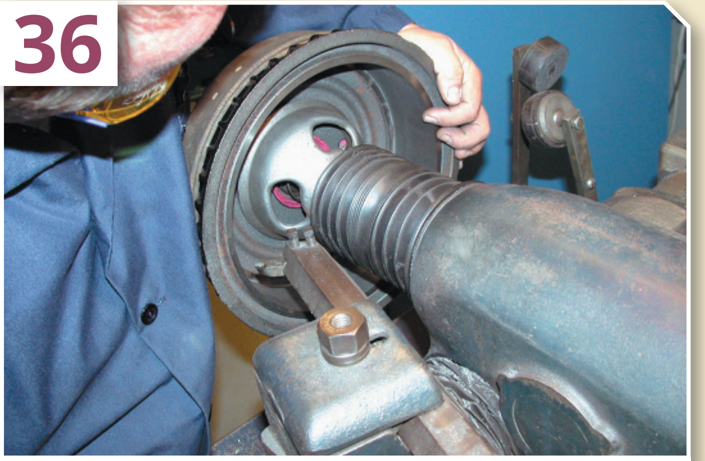
The drum will automatically move as the tool remains stationary to make the cut.

35



Turn the lathe off.

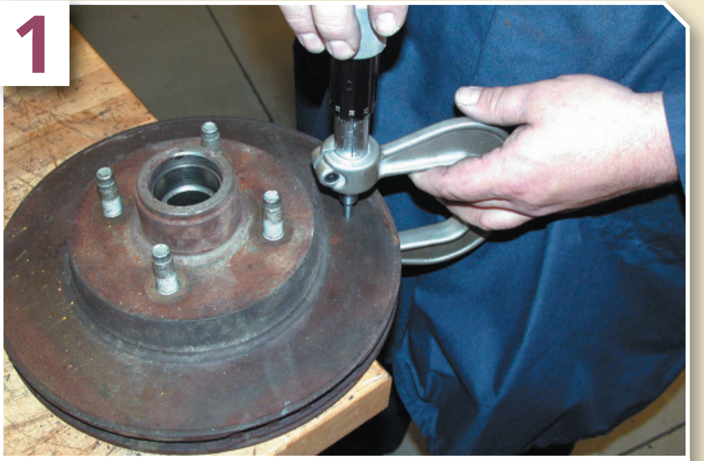
36



If additional material must be removed, proceed with the finish cut. Clean thoroughly before installing on a vehicle.

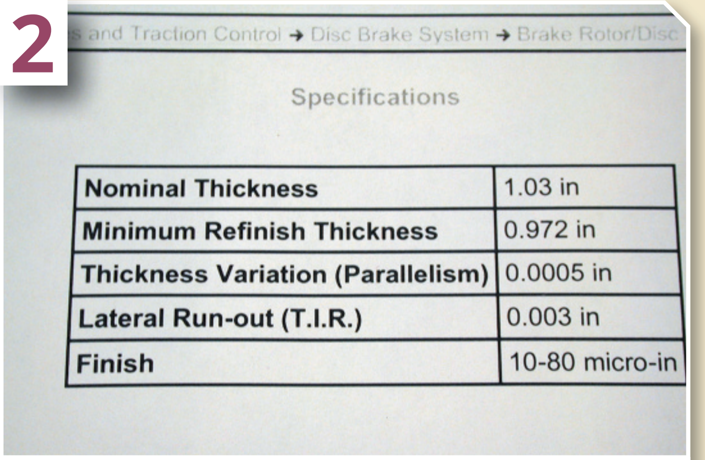
ROTOR MACHINING STEP BY STEP

1



Before machining any rotor, use a micrometer and measure the thickness of the rotor.

2



s and Traction Control → Disc Brake System → Brake Rotor/Disc

Specifications

Nominal Thickness	1.03 in
Minimum Refinish Thickness	0.972 in
Thickness Variation (Parallelism)	0.0005 in
Lateral Run-out (T.I.R.)	0.003 in
Finish	10-80 micro-in

Check the specifications for the minimum allowable thickness.

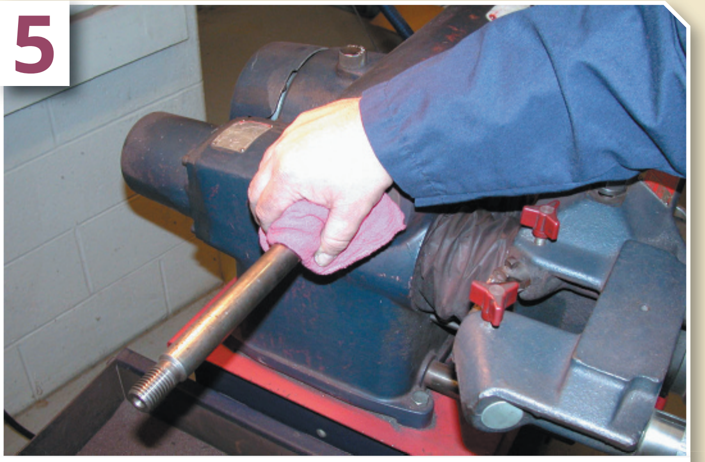
3

Visually check the rotor for evidence of heat cracks or hard spots that would require replacement (rather than machining) of the rotor.

4

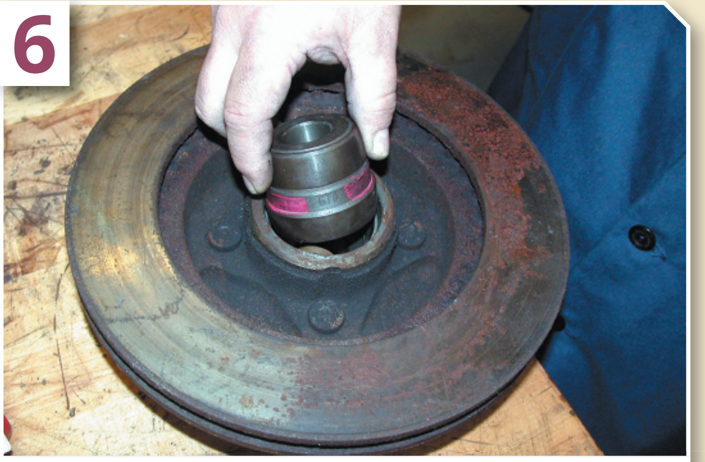
After removing the grease seal and bearings, remove the grease from the bearing races.

5



Clean and inspect the brake lathe spindle for damage or burrs that could affect its accuracy.

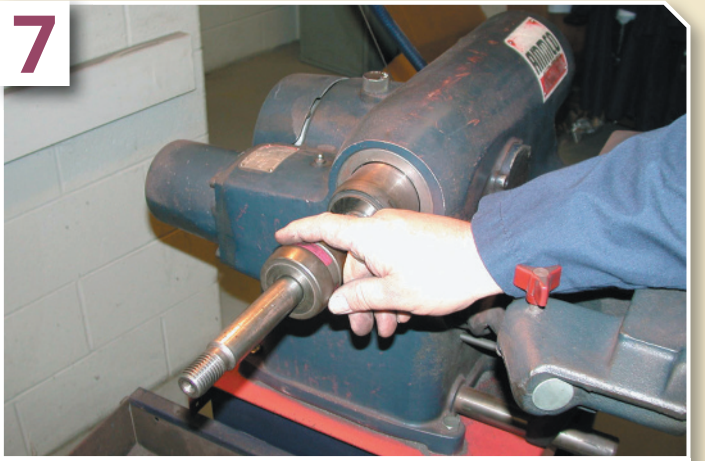
6



Select a tapered cone adapter that fits the inner bearing race.

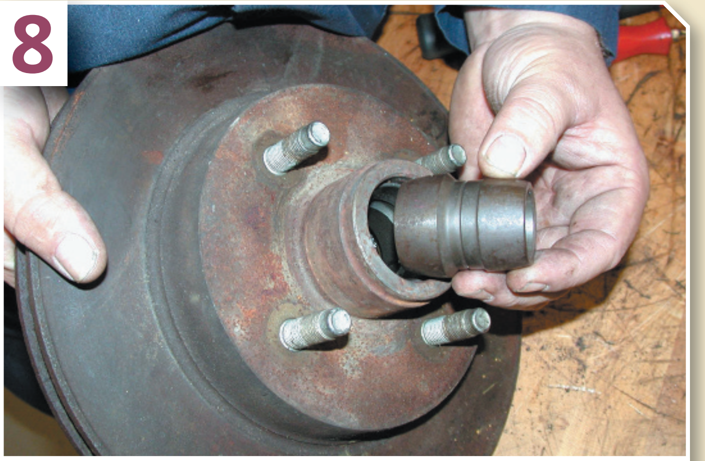
ROTOR MACHINING

7



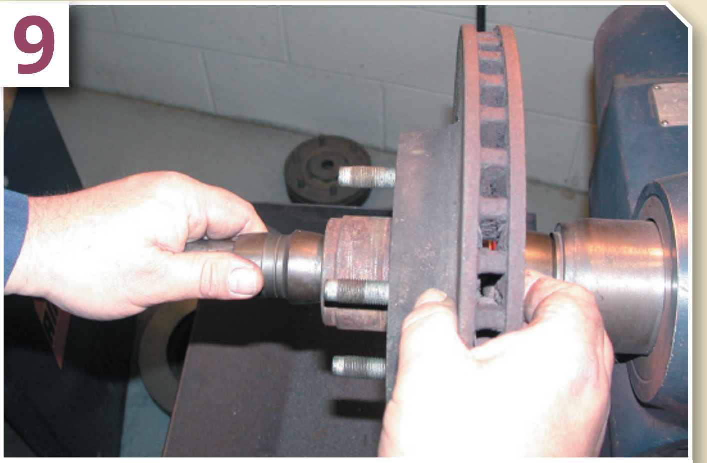
Slide the cone adapter onto the brake lathe spindle.

8



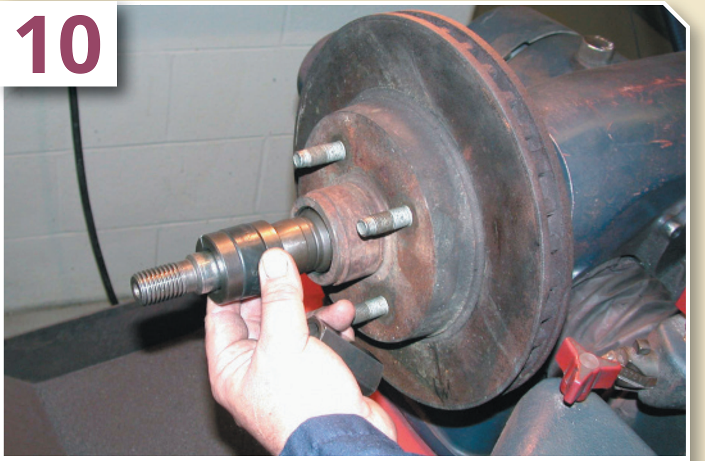
Select the proper size cone adapter for the smaller outer wheel bearing race.

9



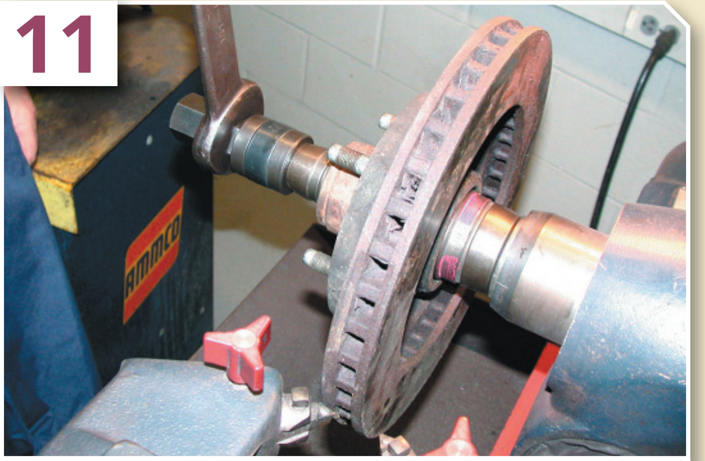
Place the rotor onto the large cone adapter and then slide the small cone adapter into the outer wheel bearing race.

10



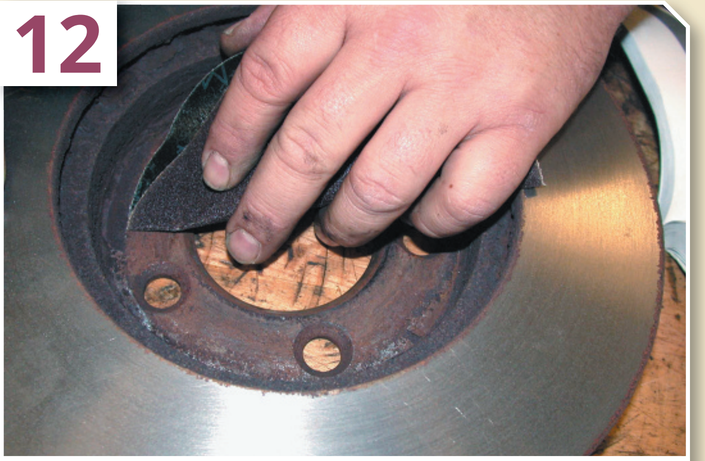
Install the self-aligning spacer (SAS) and spindle nut.

11



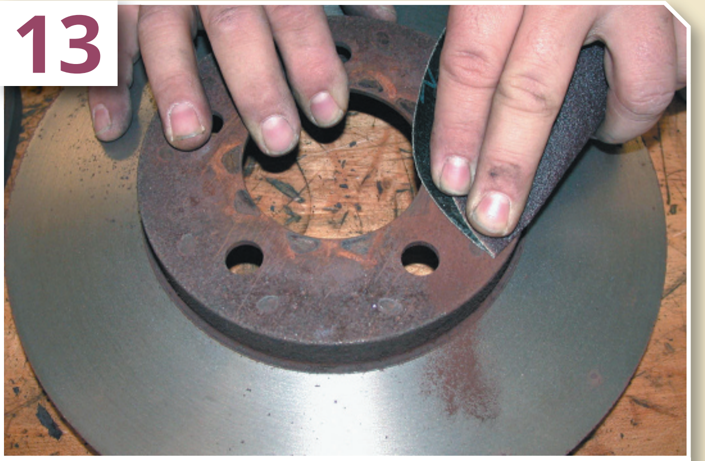
Tighten the spindle nut (usually left-hand threads).

12



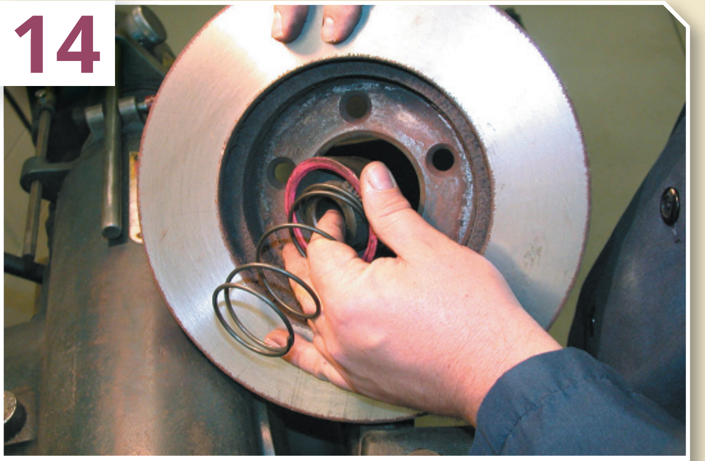
If a hubless rotor is being machined, be sure to thoroughly clean the inside surface.

13



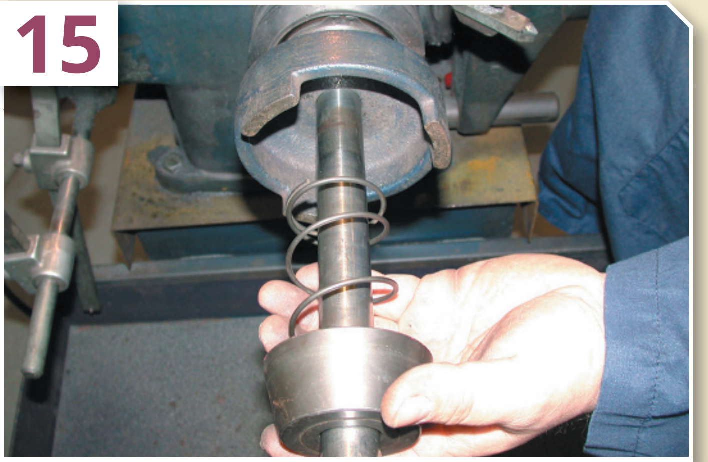
Also remove all rust from the other side of the hubless rotor.

14



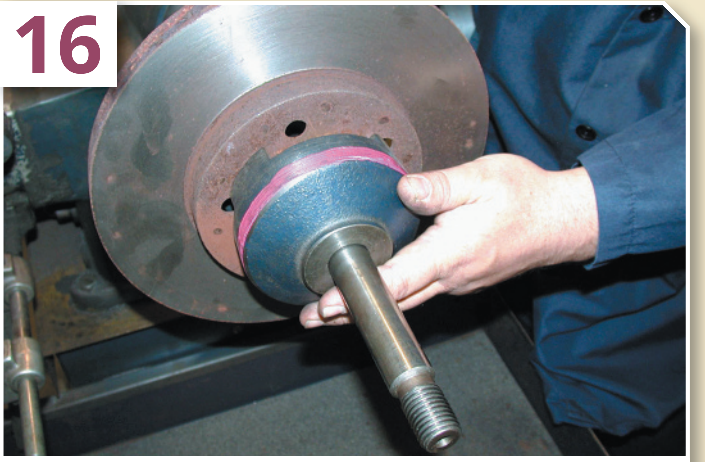
Select the proper centering cone for the hole in the center of the hub.

15



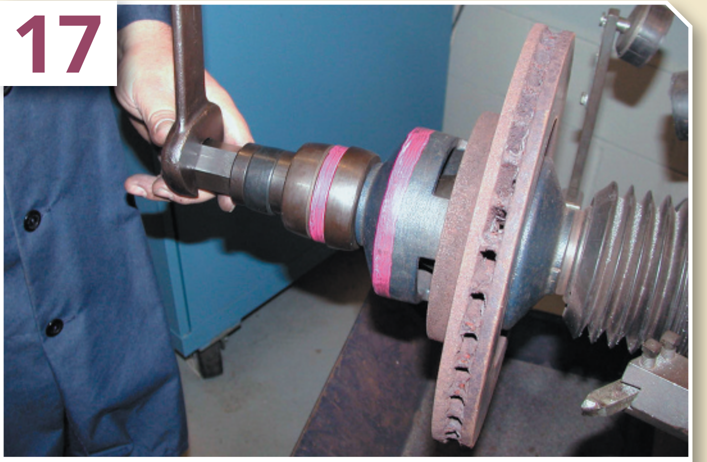
Select the proper size cone-shaped hubless adapter and the tapered centering cone with a spring in between.

16



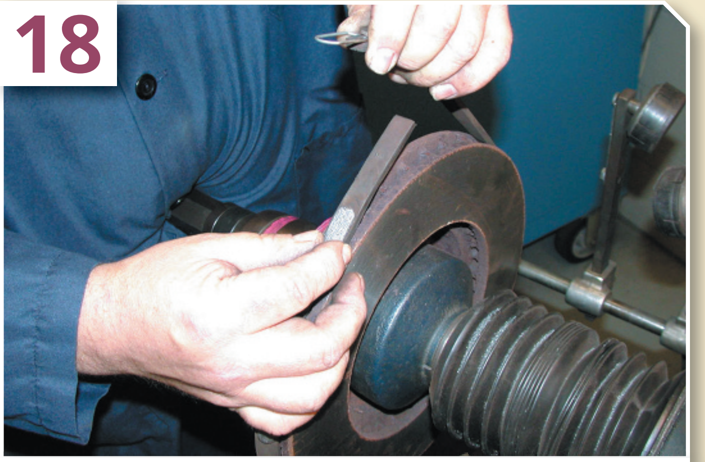
After sliding the rotor over the centering cone, install the matching hubless adapter.

17



Install the self-aligning spacer (SAS) and spindle nut.

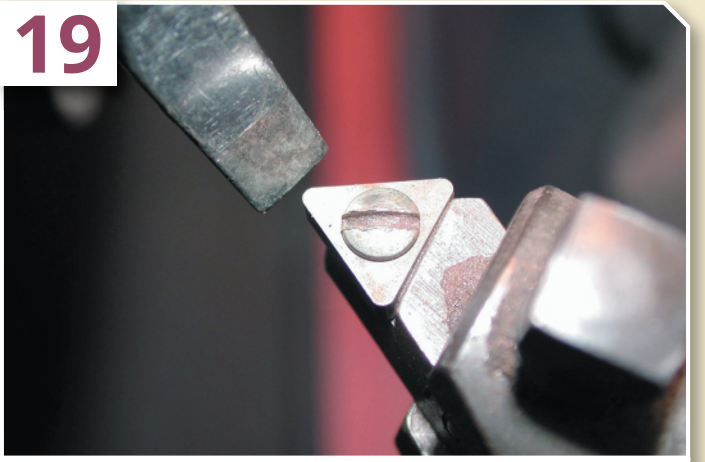
18



After the rotor has been secured to the brake lathe spindle, install the noise silencer band (dampener).

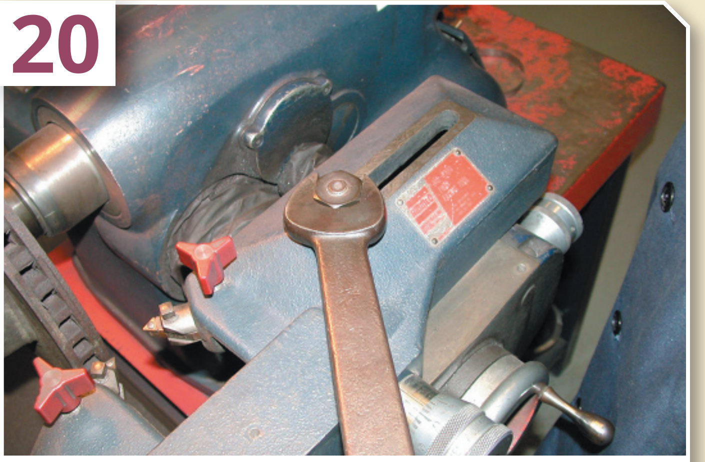
ROTOR MACHINING

19



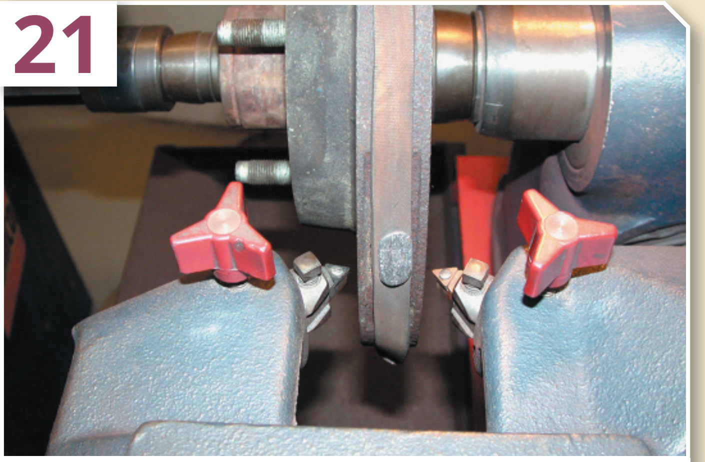
Carefully inspect the cutting bits and replace, if necessary.

20



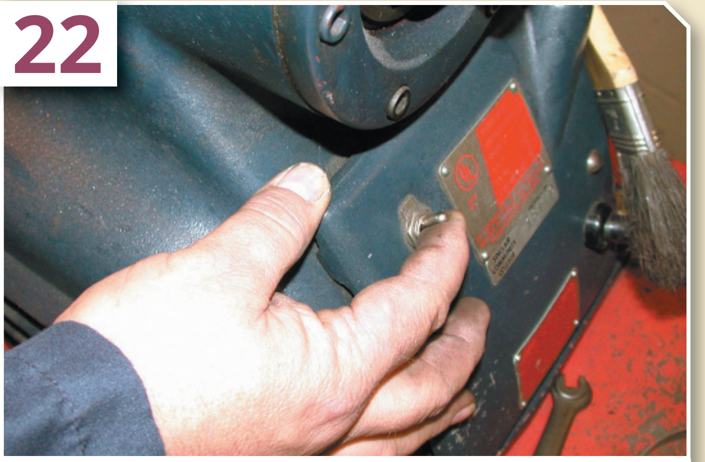
Loosen the tool holder arm.

21



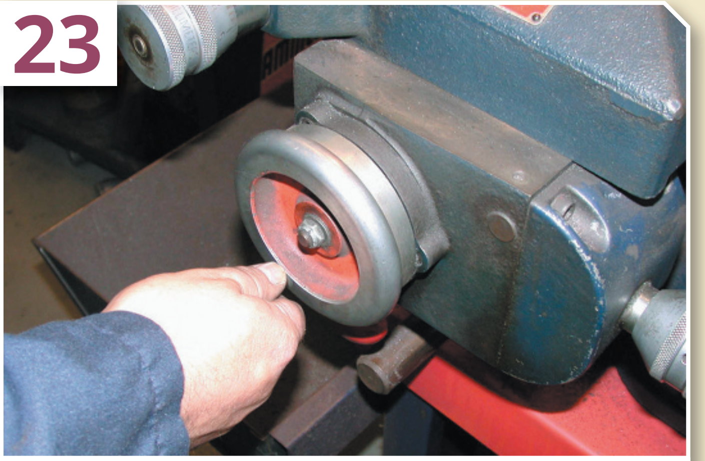
Adjust the twin cutter arm until the rotor is centered between the two cutting bits.

22



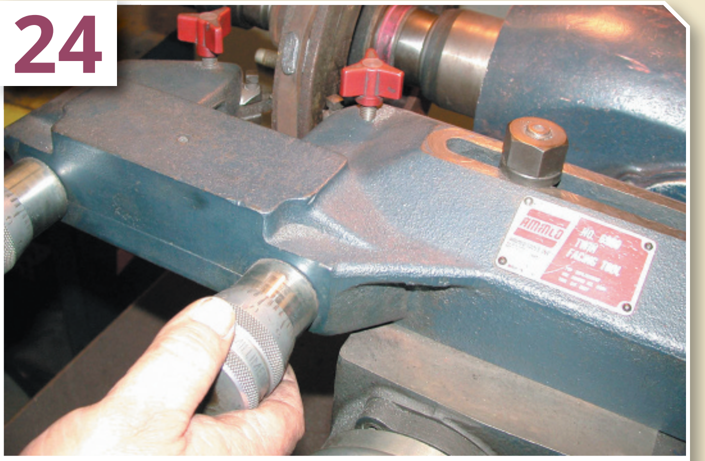
Turn the lathe on.

23



Move the cutter arm toward the center of the rotor, placing the cutting bits in about the center of the friction surface.

24

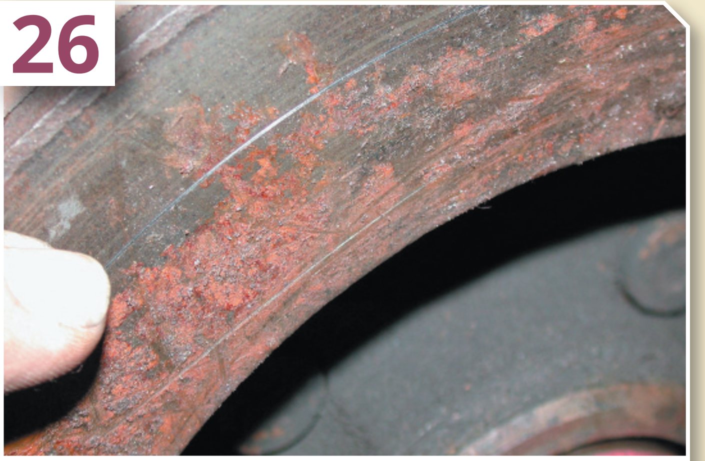


Turn one cutting bit into the surface of the rotor to make a scratch cut. This step checks the lathe setup for accuracy.

25

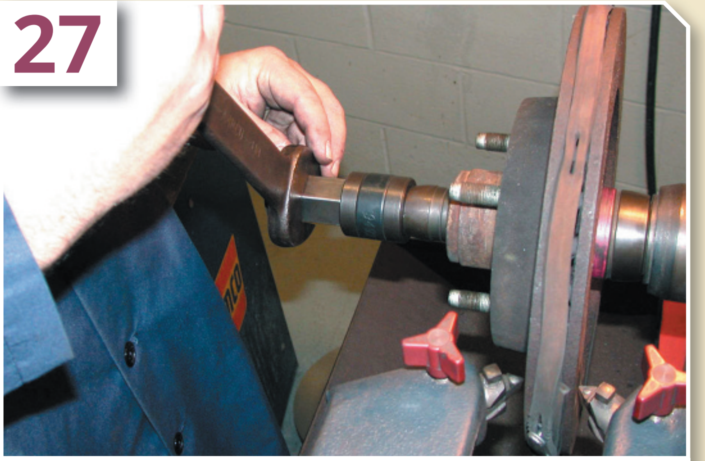
Turn the lathe off.

26



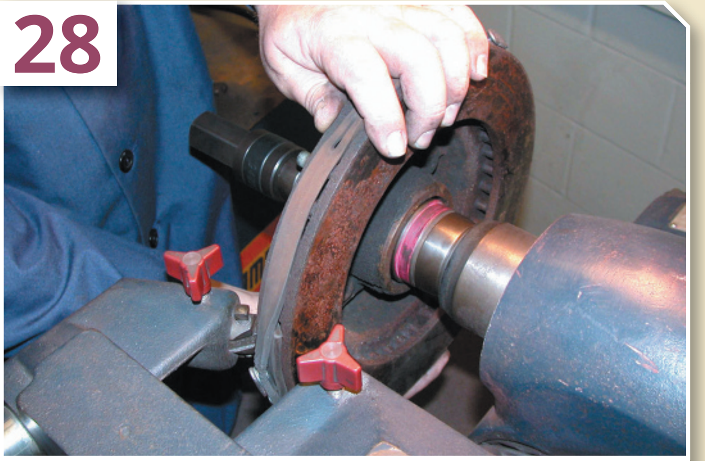
Observe the first scratch cut.

27



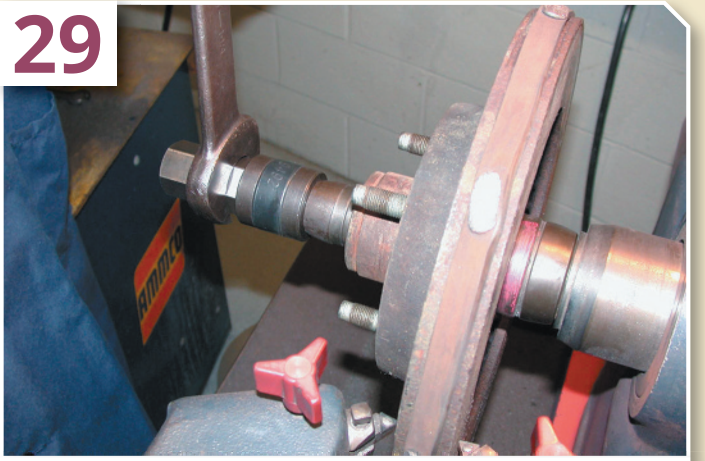
Loosen the spindle retaining nut.

28



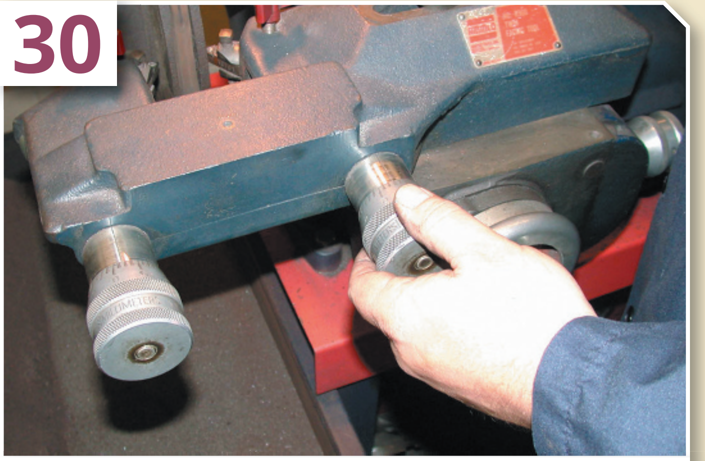
Rotate the rotor 180 degrees (one-half turn) on the spindle of the brake lathe.

29



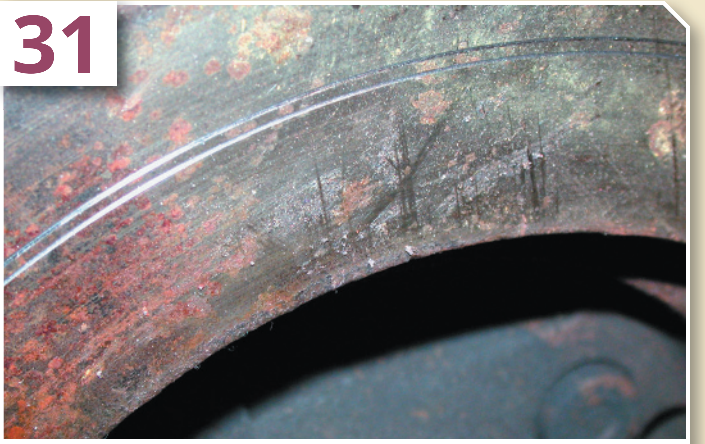
Tighten the spindle nut.

30



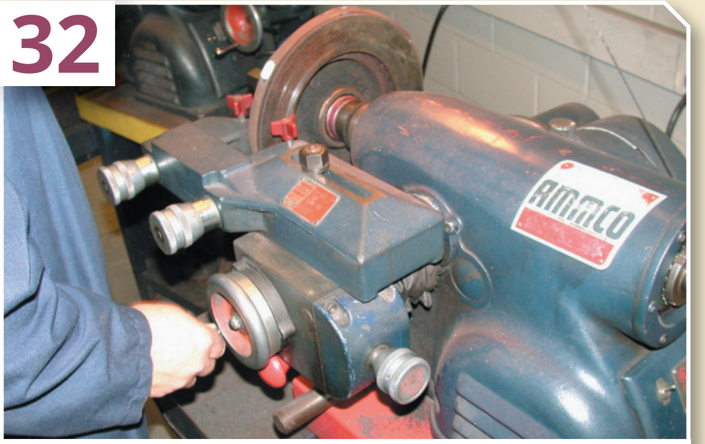
Turn the lathe back on and turn the cutting bit slightly into the rotor until a second scratch cut is made.

ROTOR MACHINING



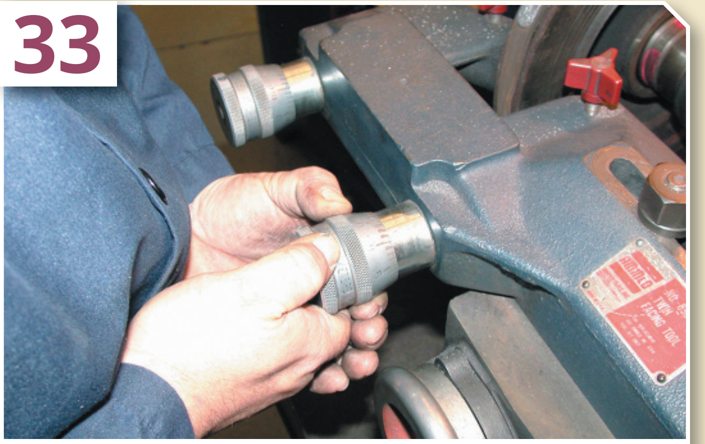
31

If the second scratch cut is in the same location as the first scratch cut or extends all around the surface of the rotor, then the rotor is properly installed on the lathe.



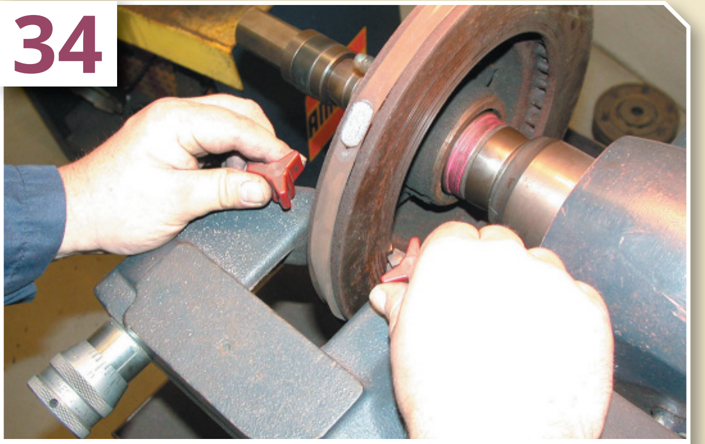
32

Start the machining process by moving the twin cutters to about the center of the rotor friction surface.



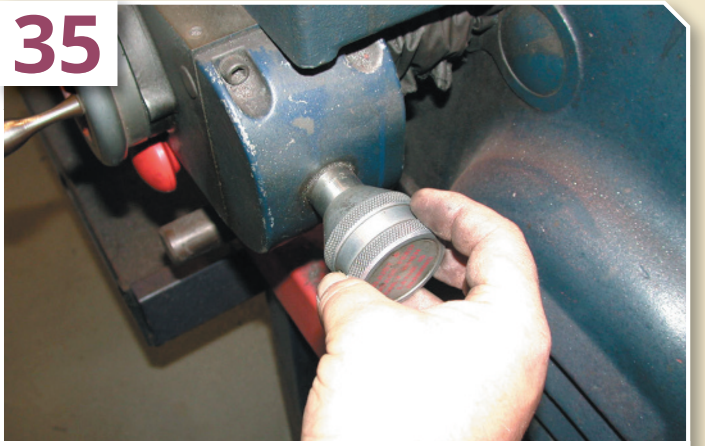
33

Turn the cutting bits inward until they touch the rotor and zero the depth adjustment.



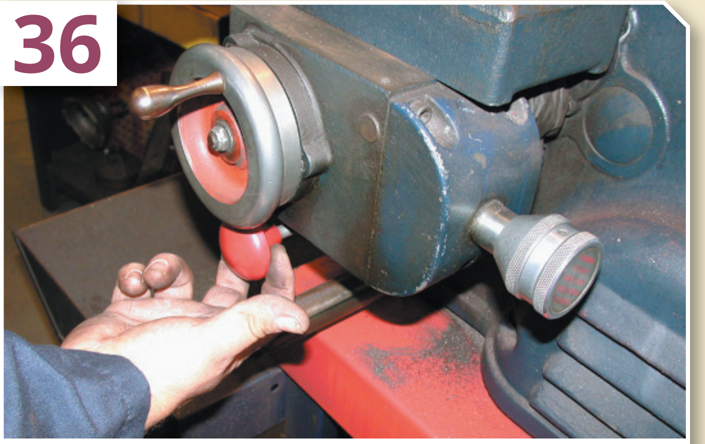
34

Adjust the twin cutters, then dial in the amount of depth (0.005–0.010 in. per side for a rough cut or 0.002 in. for a finish cut) and lock the adjustment so that vibration will not change the setting.



35

Turn the feed control knob until the desired feed rate is achieved for the first or rough cut (0.006–0.010 in. per revolution) or finish cut (0.002 in. per revolution).

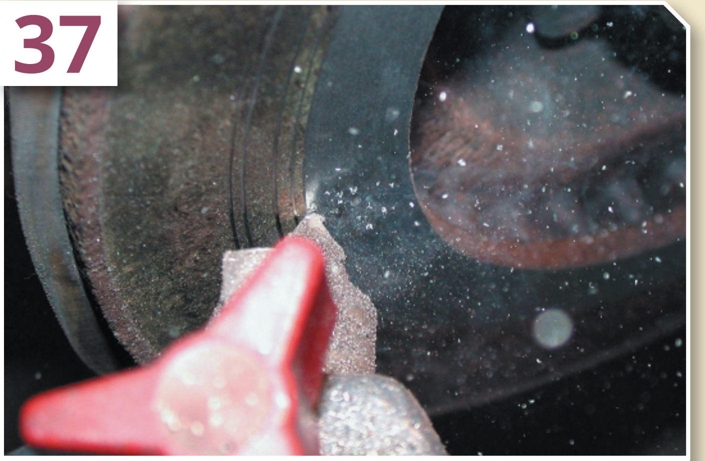


36

Engage the automatic feed.

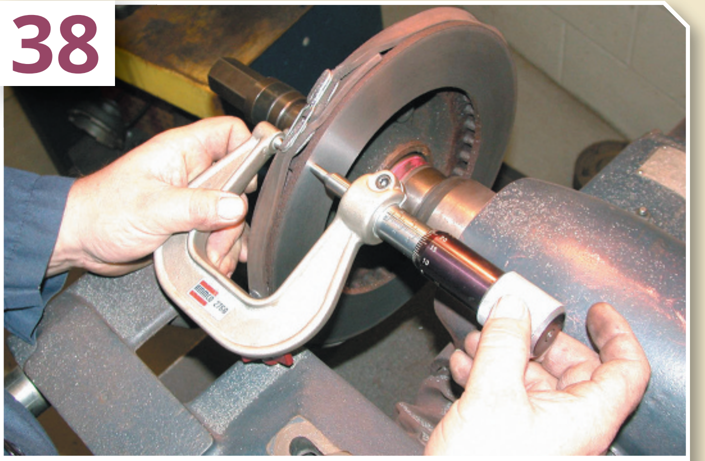
STEP BY STEP

37



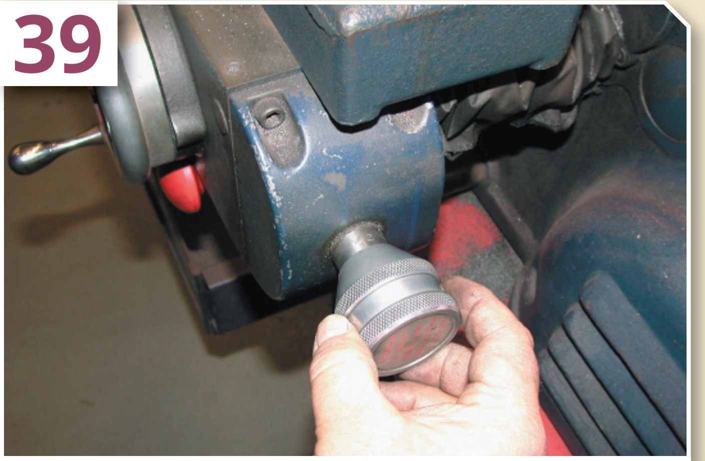
Observe the machining operation.

38



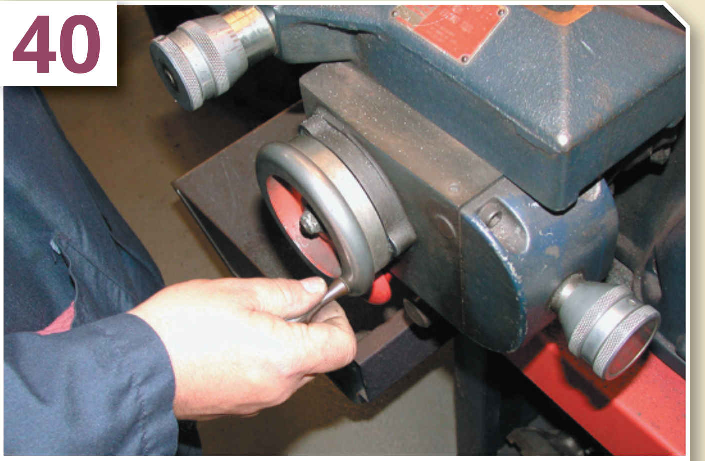
After the cutting bits have cleared the edge of the rotor, turn the lathe off and measure the thickness of the rotor.

39



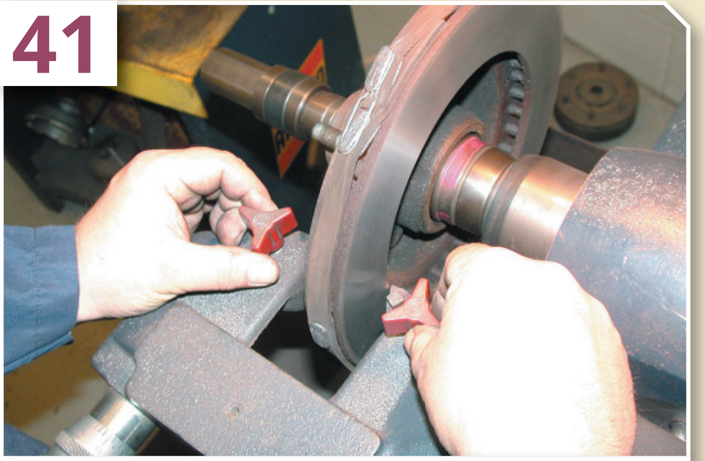
Readjust the feed control to a slow rate (0.002 in. per revolution or less) for the finish cut.

40



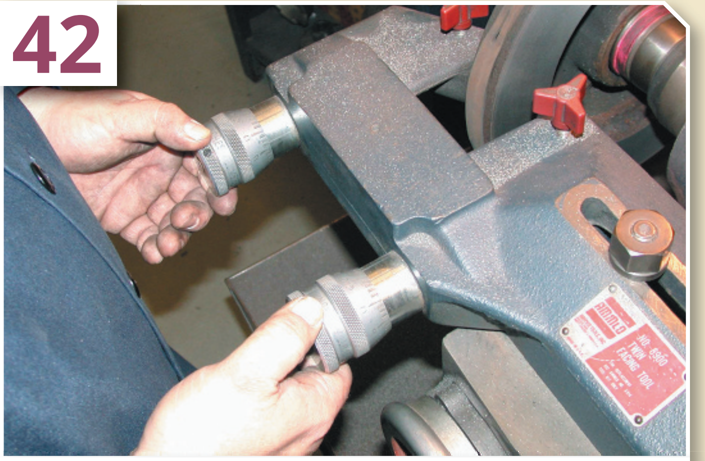
Reposition the cutting bits for the finish cut.

41



Loosen the adjustment locks.

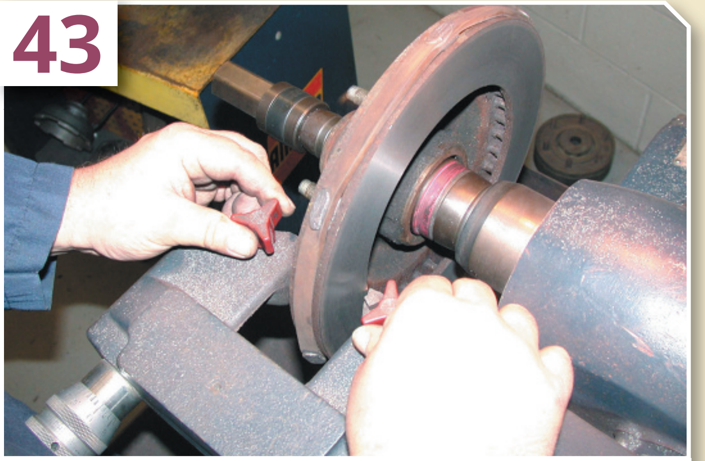
42



Turn the depth of the cut for the finish cut (0.002 in. maximum).

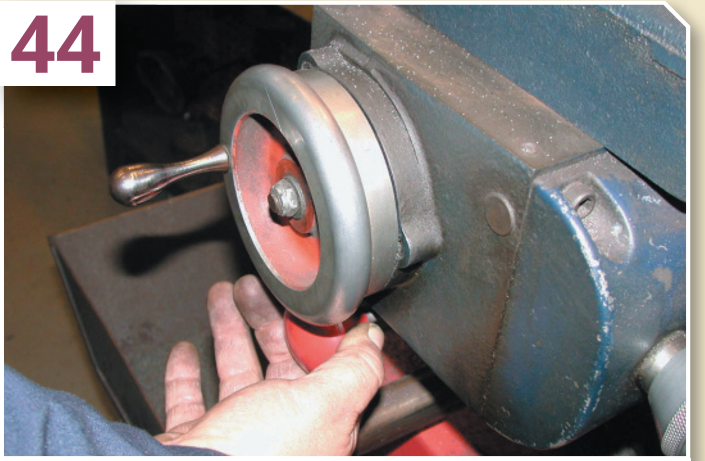
ROTOR MACHINING

43



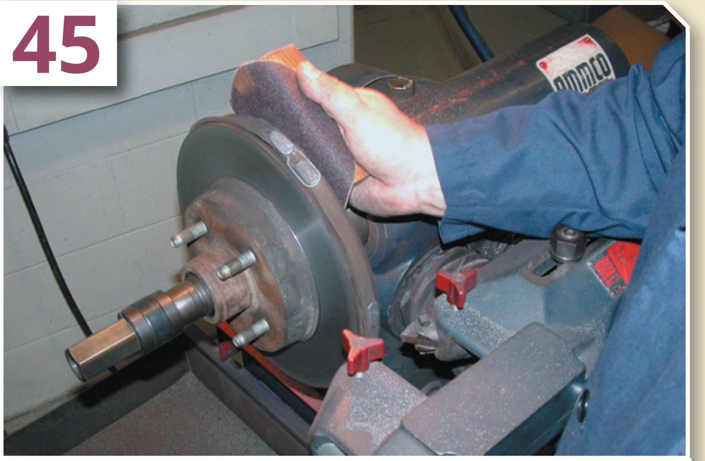
Lock the adjustment.

44



Engage the automatic feed.

45



Use 150-grit aluminum-oxide sandpaper on a block of wood for 60 seconds per side on a grinder to give a nondirectional and smooth surface to both sides of the rotor.

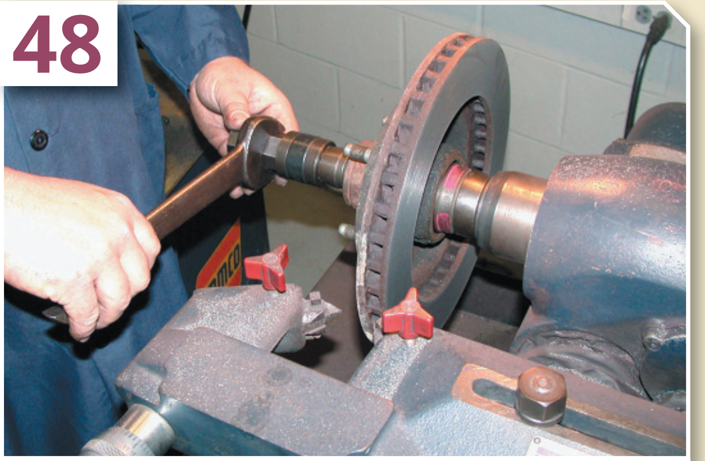
46

After the sanding or grinding operation, thoroughly clean the machined surface of the rotor to remove any and all particles of grit that could affect the operation and life of the disc brake pads.

47

Remove the silencer band.

48



Loosen the spindle retaining nut and remove the rotor.

ON-THE-VEHICLE LATHE

STEP BY STEP

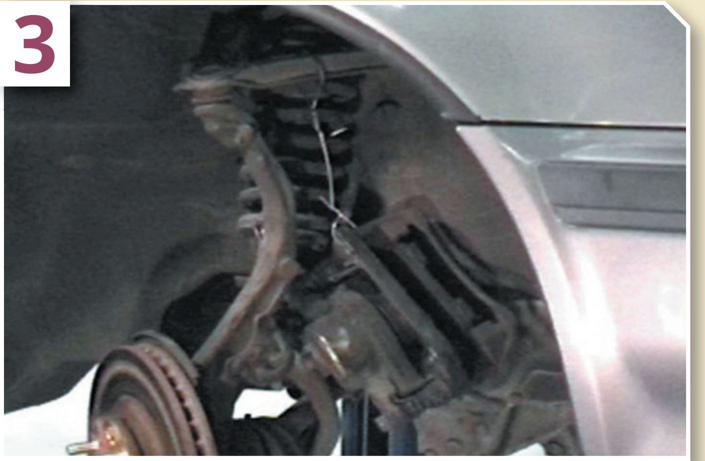
1

Prepare to machine a disc brake rotor using an on-the-vehicle lathe by properly positioning the vehicle in the stall and hoisting the vehicle to a good working height.

2

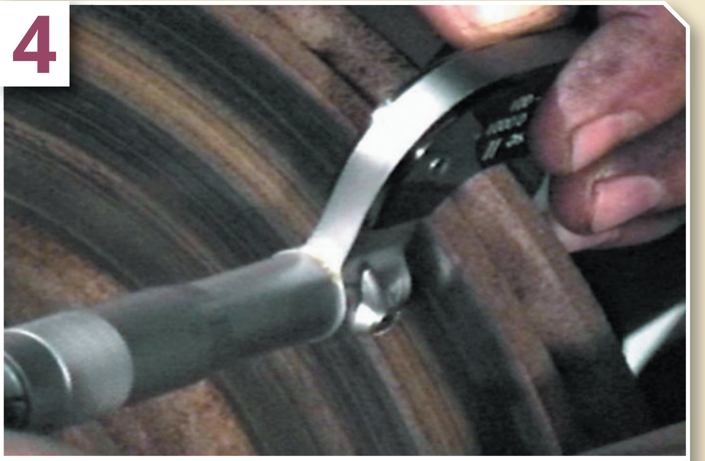
Remove the wheels and place them out of the way.

3



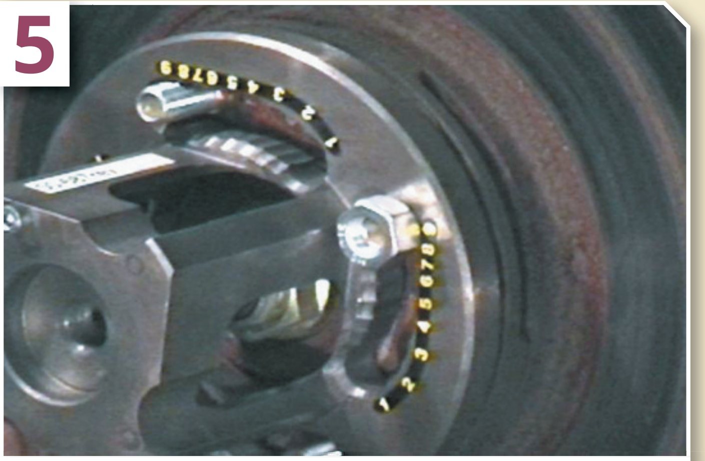
Remove the disc brake caliper and use a wire to support the caliper out of the way of the rotor.

4



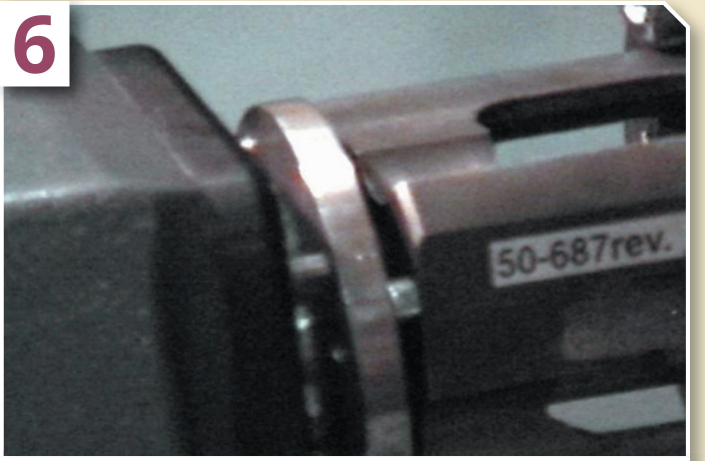
Measure the rotor thickness and compare it with factory specifications before machining. If a discard thickness is specified, be sure to allow an additional 0.015 inch for wear.

5



Install the hub adapter onto the hub and secure it using the wheel lug nuts.

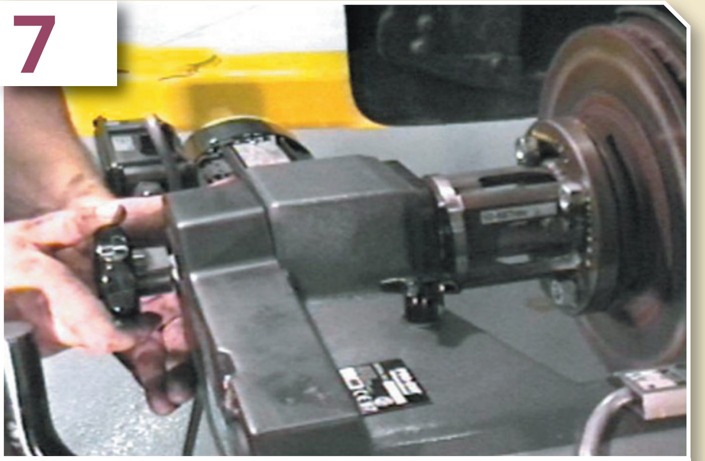
6



Engage the drive unit by aligning the hole in the drive plate with the raised button on the adapter.

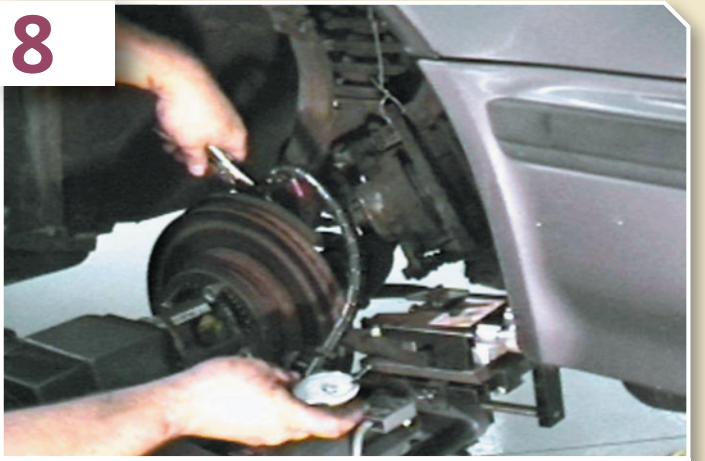
ON-THE-VEHICLE LATHE

7



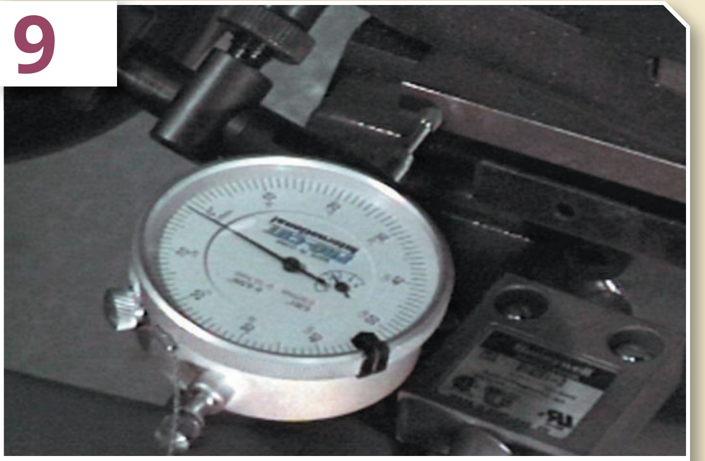
Use the thumb wheel to tighten the drive unit to the adapter.

8



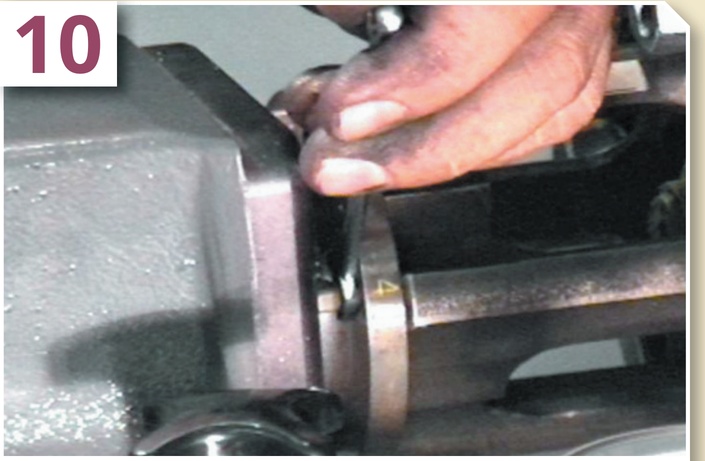
Attach a dial indicator to a secure part on the vehicle and position the dial indicator on a flat portion of the lathe to measure the lathe runout.

9



Rotate the wheel or turn the lathe motor on and measure the amount of runout.

10

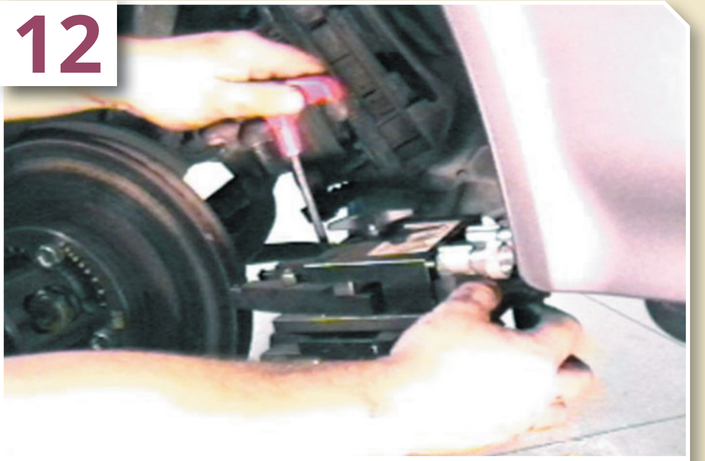


Use a wrench to adjust the runout using the four numbers stamped on the edge of the drive flange as a guide.

11

After the hub runout is adjusted to 0.005 in. or less, remove the dial indicator from the vehicle.

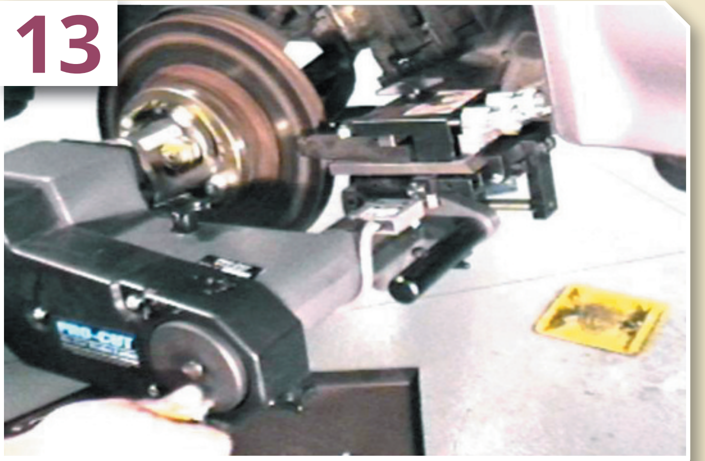
12



Using a T-handle Allen wrench, adjust the cutter arms until they are centered on the disc brake rotor.

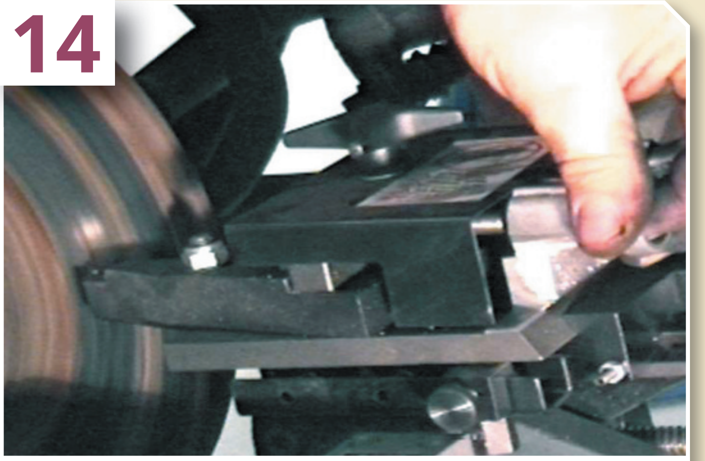
STEP BY STEP

13



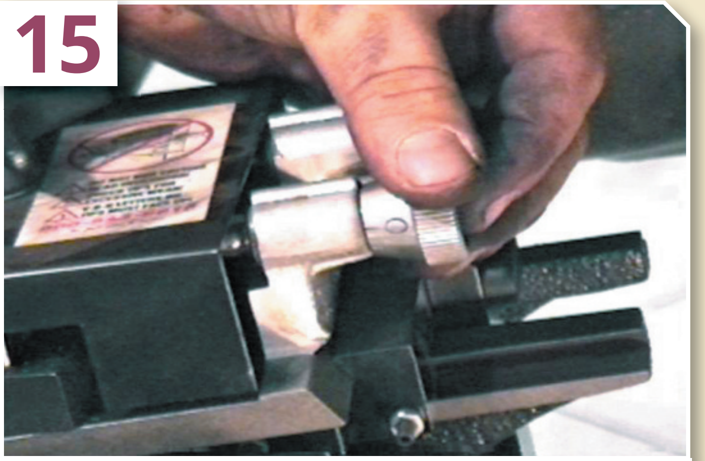
Move the cutters to the center of the rotor.

14



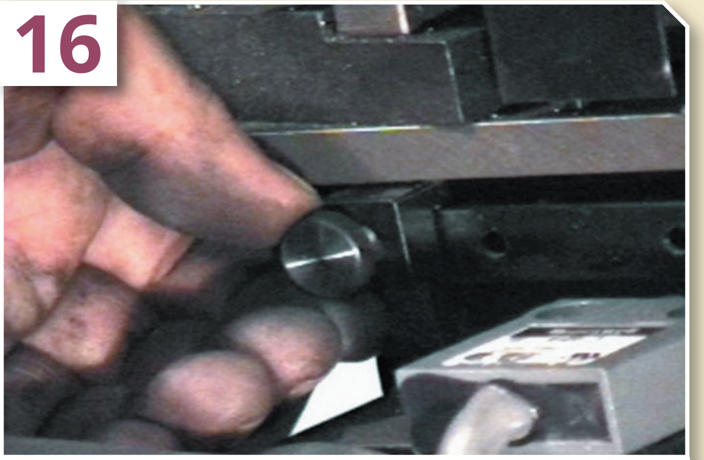
Adjust the cutter depth until each cutter barely touches the rotor.

15



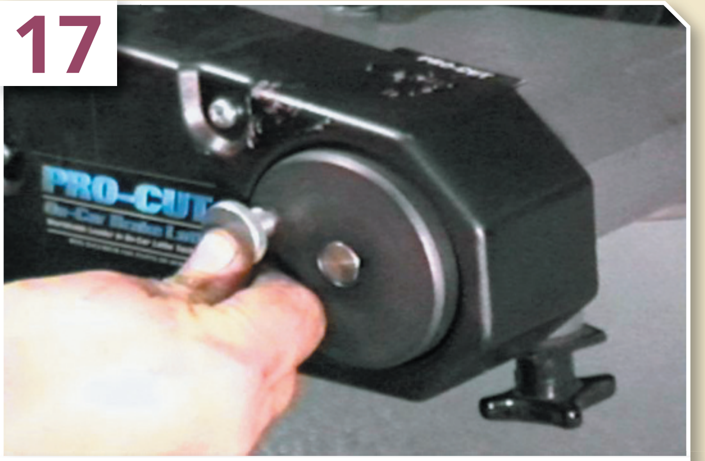
Position the cutters to the inside edge of the rotor surface and adjust the cutters to the desired depth of cut.

16



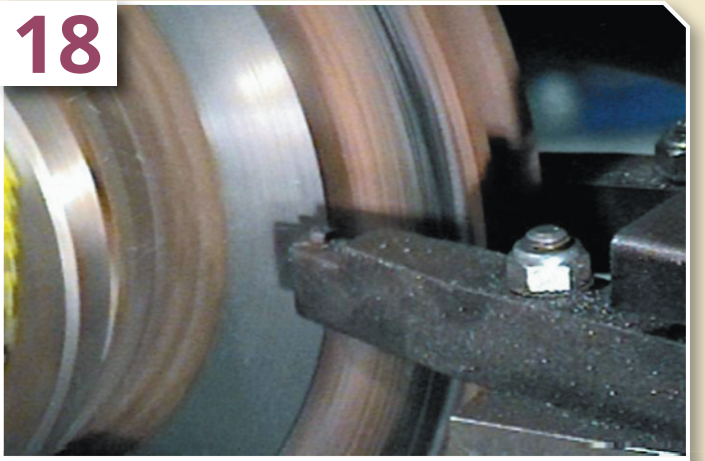
Adjust the automatic shut-off so the lathe will turn itself off at the end of the cut.

17



Turn the lathe on by depressing the start button.

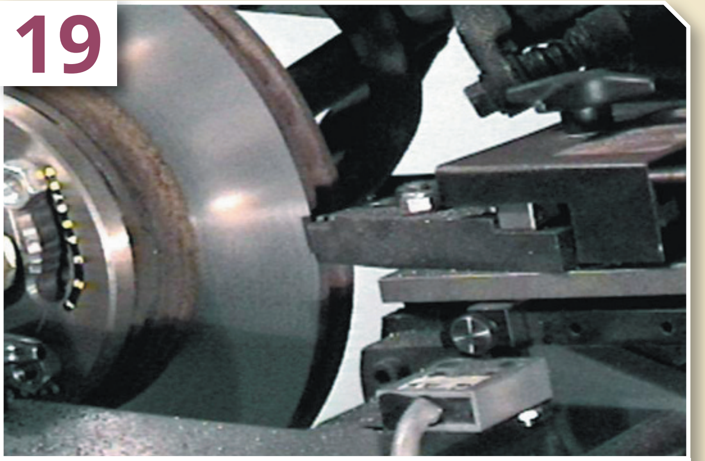
18



Monitor the machining operations as the lathe automatically moves the cutters from the center toward the outside edge of the rotor.

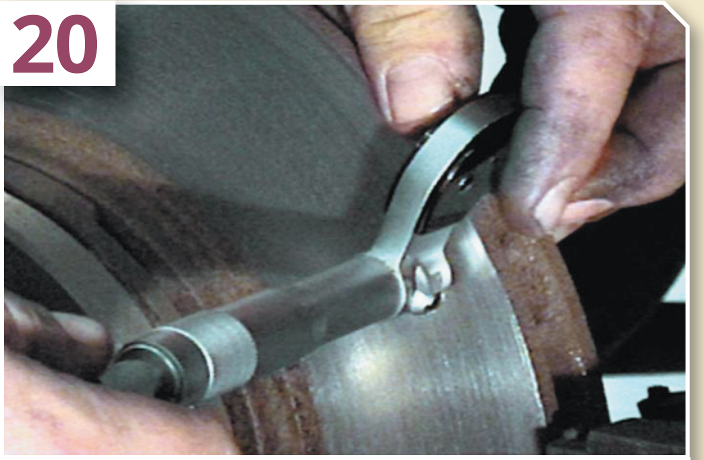
ON-THE-VEHICLE LATHE

19



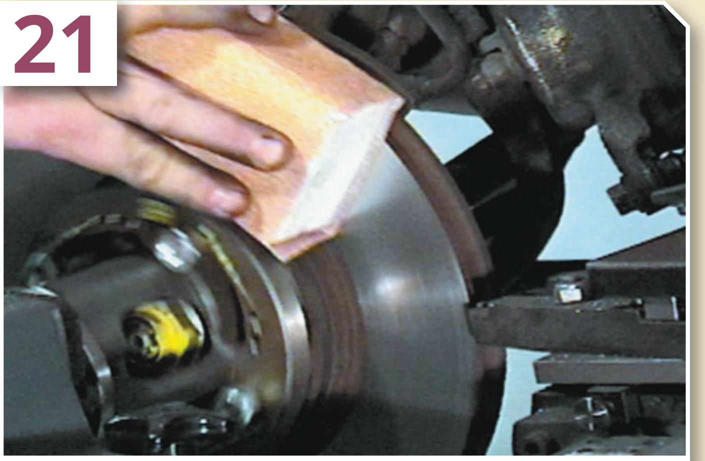
After the lathe reaches the outside edge of the rotor, the drive motor should stop.

20



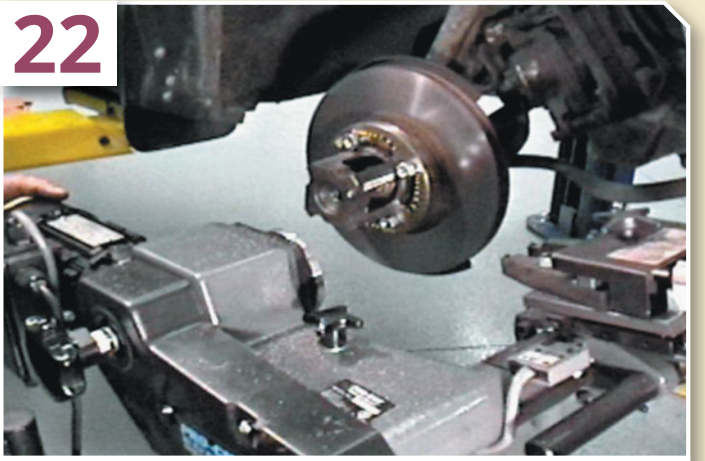
Measure the thickness of the rotor after machining to be certain that the rotor thickness is within service limits.

21



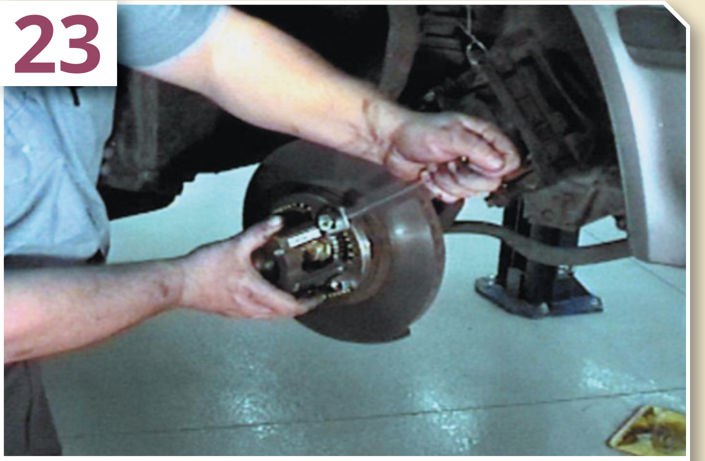
The technician is using 150-grit aluminum-oxide sandpaper and a wood block for 60 seconds on each side of the rotor to provide a smooth surface finish.

22



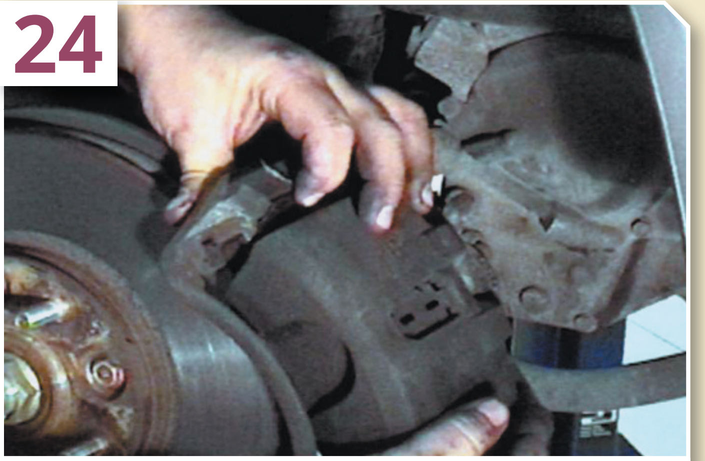
After completing the machining and resurfacing of the rotor, unclamp the drive unit from the hub adapter and clean the rotor.

23



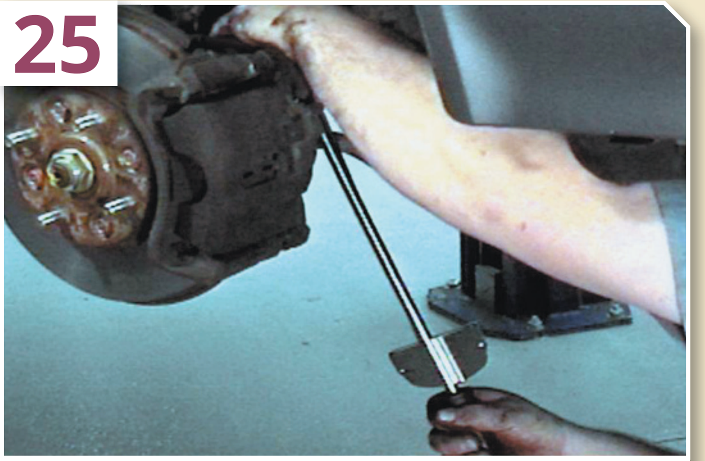
After the drive unit has been removed, remove the lug nuts holding the adapter to the rotor hub.

24



After removing the hub adapter, the caliper can be reinstalled.

25

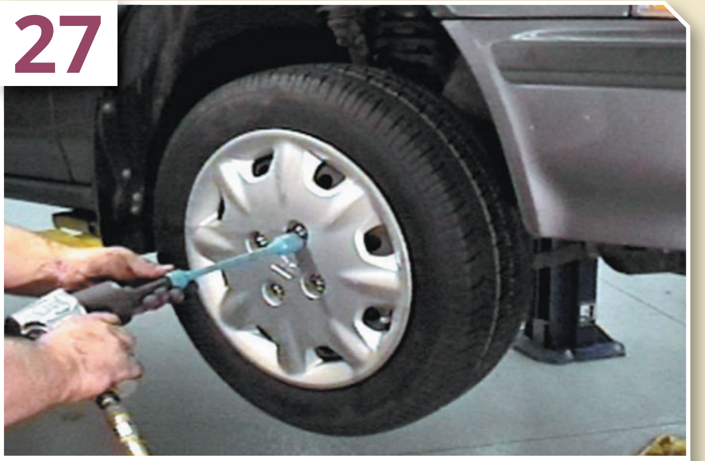


Be sure to torque the caliper retaining bolts to factory specifications.

26

Install the wheel and wheel cover. On this vehicle, the wheel cover must be installed before the lug nuts because the lug nuts hold the wheel cover on the wheel.

27



Always use a torque wrench or a torque-limiting adapter with an air impact wrench as shown here when tightening lug nuts.

28

Pump the brake pedal several times to restore proper brake pedal height. Check and add brake fluid as necessary before moving the vehicle.

POWER BRAKE UNIT OPERATION, DIAGNOSIS, AND SERVICE

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Discuss the need for power brake assist.
- State the principles of vacuum.
- Discuss vacuum booster theory.
- Discuss the operation of a vacuum check valve.
- Discuss the operation of a vacuum brake booster.
- Describe dual-diaphragm vacuum boosters.
- Discuss the brake assist system.
- Discuss the vacuum booster operation test.
- Describe the vacuum booster leak test.
- Describe the hydraulic system leak test.
- Describe how to adjust the pushrod length.
- Explain the operation and diagnosis of Hydro-Boost hydraulic brake booster.
- List Hydro-Boost symptoms and possible causes.

KEY TERMS:

Atmospheric pressure 1247 • Brake assist system (BAS) 1253 • Dual-diaphragm vacuum booster 1252 • in. Hg (inches of mercury) 1248 • mm Hg (millimeters of mercury) 1248 • Power chamber 1249 • Pressure differential 1247 • Supplemental brake assist (SBA) 1254 • Tandem-diaphragm vacuum booster 1252 • Vacuum 1247

THE NEED FOR POWER BRAKE ASSIST

To double the stopping power of a disc brake, the driver must double the force on the brake pedal. This is the reason that most vehicles equipped with disc brakes are power assisted, even on small, lightweight vehicles. The use of semimetallic brake pads also requires greater force. The most commonly used power-assisted units are vacuum operated.

When a power booster is fitted, the brake pedal ratio is decreased and the master cylinder bore size is increased. The combined effect of these changes is to reduce pedal effort, while greatly increasing pedal reserve. ● **SEE FIGURE 104–1**.

Power boosters do not alter the hydraulic system and they still allow braking even if the booster fails or its power supply is cut off. All boosters have a power reserve that provides assist for at least one hard stop and sometimes several light brake applications, even after power is lost. However, because power brake systems are designed with the added force of the booster taken into account, the amount of brake pedal pressure required to slow or stop a vehicle is much higher than in a non-boosted system once the reserve is used up. For this reason, some vehicles with power brakes have a brake pedal that is wide enough to allow two-foot braking should the booster fail. ● **SEE FIGURE 104–2**.

PRINCIPLES OF VACUUM

Most vacuum-powered brake boosters get their vacuum supply from the engine intake manifold. An engine is essentially a big air pump because the pistons move up and down in the cylinders to pump in air and fuel, and pump out exhaust. They do this by creating differences in air pressure.

As a piston moves downward on an intake stroke with the intake valve open, it creates a larger area inside the cylinder for air to fill. This lowers the air pressure within the cylinder, and the higher pressure air outside the engine flows in through the intake manifold in an attempt to fill the low-pressure area. Although it may seem as though the low pressure is pulling air into the engine, it is really the higher pressure outside that forces air in. The difference in pressure between two areas is called a **pressure differential**.

Because throttle valves and manifold shape restrict intake airflow, high-pressure air from outside the engine is almost never able to move into the cylinders fast enough to fill the space created. As a result, gasoline-powered internal-combustion engines normally operate with a low-pressure area, or partial vacuum, in the intake manifold. The term **vacuum** is used to refer to any pressure lower than **atmospheric pressure**. Atmospheric pressure varies with altitude, but is approximately 14.7 pounds per square inch (PSI) at sea level. ● **SEE FIGURE 104–3**.

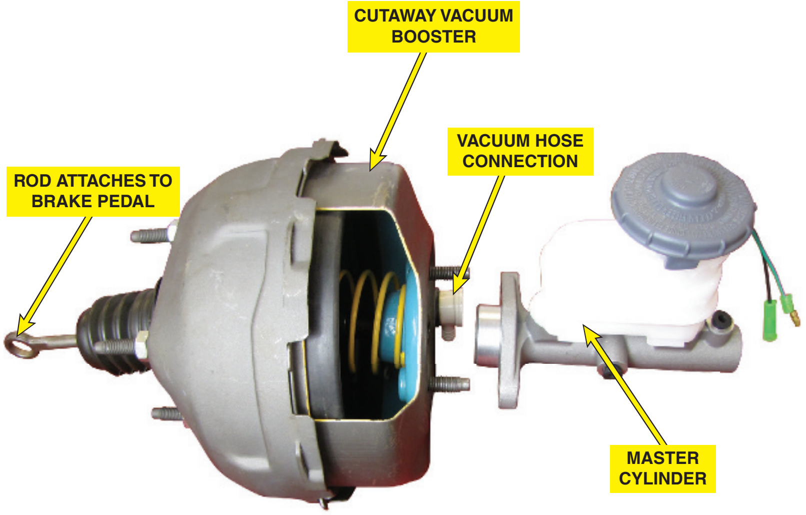

FIGURE 104–1 Typical vacuum brake booster assembly. The vacuum hose attaches to the intake manifold of the engine.

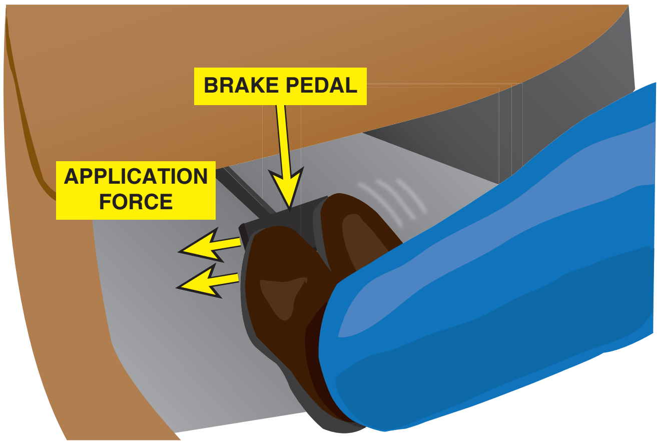

FIGURE 104–2 A wide brake pedal allows two-foot braking if power assist is lost.

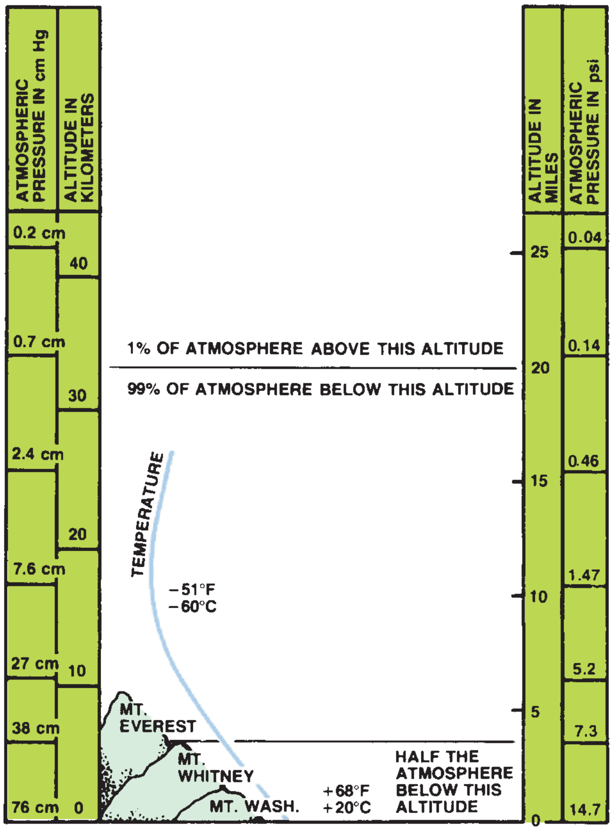

FIGURE 104–3 Atmospheric pressure varies with altitude.

MEASURING VACUUM Vacuum is measured in **inches of mercury (in. Hg)** or in **millimeters of mercury (mm Hg)**, a figure that indicates how far a column of mercury in a tube will rise when a vacuum is applied at one end and atmospheric pressure at the other. Vacuum is a measurement of the pressure differential between the lower pressure inside the tube and the higher pressure outside it.

A perfect vacuum is about 30 in. Hg (762 mm Hg). However, a perfect vacuum occurs only in space and is never achieved in an engine's intake manifold. Manifold vacuum varies with throttle position. The lowest manifold vacuum (highest pressure) occurs when the throttle is wide open with the engine under load. The highest manifold vacuum (lowest pressure) may be as much as 24 in. Hg (610 mm Hg) when the vehicle is rolling rapidly downhill in gear with the throttle closed. Manifold vacuum at idle typically falls between 15 and 20 in. Hg (381 and 508 mm Hg), and most vacuum brake boosters are designed to operate with vacuum levels in this range.

BOOSTER VACUUM SUPPLY Vacuum boosters get their vacuum supply from the engine intake manifold. Diesel engines, however, run unthrottled (engine speed is controlled strictly by the amount of fuel injected) and have little or no intake manifold vacuum. If a vehicle with a diesel engine is equipped with a vacuum-powered brake booster, it must also be fitted with an auxiliary vacuum pump.

Some small gasoline-powered and diesel engines use a belt-driven add-on pump. ● **SEE FIGURE 104–4**.

An electrically powered vacuum pump is turned on and off by a pressure switch on the booster. This means they operate only when needed and thus reduce power drain on the engine. ● **SEE FIGURE 104–5**.

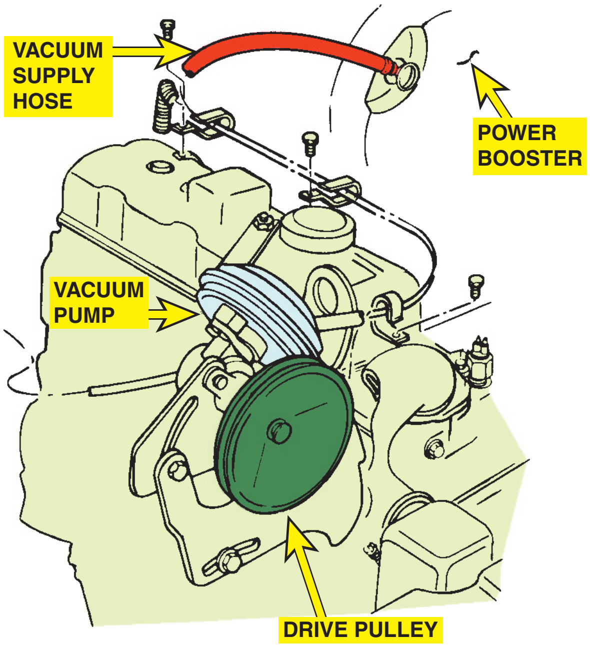

FIGURE 104–4 A belt-driven auxiliary vacuum pump.

VACUUM BOOSTER THEORY

Vacuum boosters use the principle of pressure differential to increase brake application force. The typical vacuum booster has a **power chamber** separated into two smaller chambers by a flexible diaphragm. When air pressure is greater on one side of the diaphragm than the other, a pressure differential is created. In an attempt to equalize pressure in the two chambers, the higher pressure exerts a force that moves the diaphragm toward the lower pressure area. Rods attached to the diaphragm transmit this force, in addition to the force the driver exerts on the brake pedal, to the master cylinder.

The amount of force created in this manner is proportional to the difference in pressure between the two sides. In other words, the greater the pressure differential, the greater the force. To calculate the force, the pressure differential is multiplied by the diaphragm surface area. For example, if a power booster diaphragm has atmospheric pressure (14.7 PSI) on one side, and a typical intake manifold vacuum of 20 in. Hg (10 PSI of absolute pressure), the pressure differential acting on the diaphragm would be as follows:

14.7 PSI − 10 PSI = 4.7 PSI

TECH TIP

Check the Vacuum, Then the Brakes

A customer complained of a very rough idle and an occasional pulsating brake pedal. The customer was certain that the engine required serious work since there were over 100,000 miles on the vehicle. During the troubleshooting procedure, a spray cleaner was used to find any vacuum (air) leaks. A large hole was found melted through a large vacuum hose next to the vacuum hose feeding the vacuum-operated power brake booster.

After repairing the vacuum leak, the vehicle was test driven again to help diagnose the cause of the pulsating brake pedal. The engine idled very smoothly after the vacuum leak was repaired and the brake pulsation was also cured. The vacuum leak resulted in lower-than-normal vacuum being applied to the vacuum booster. During braking, when engine vacuum is normally higher (deceleration), the vacuum booster would assist, then not assist when the vacuum was lost. This on-and-off supply of vacuum to the vacuum booster was noticed by the driver as a brake pulsation. Always check the vacuum at the booster whenever diagnosing any brake problems. Most vehicle manufacturers specify a minimum of 15 in. Hg of vacuum at the booster. The booster should be able to provide at least two or three stops even with no vacuum. The booster should also be checked to see if it can hold a vacuum after several hours. A good vacuum booster, for example, should be able to provide a power assist after sitting all night without starting the engine.

If we once again multiply this times the area of the diaphragm, the result is as follows:

4.7 PSI × 50 sq. in = 235 pounds of force

Vacuum booster diaphragms are sized to fit specific applications and provide the necessary application force. Most vacuum boosters are capable of providing hundreds of pounds of application force. ● **SEE FIGURE 104–6**.

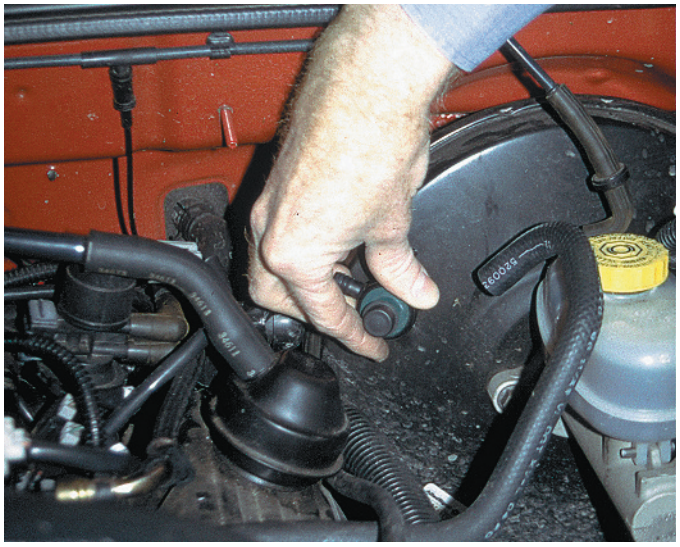
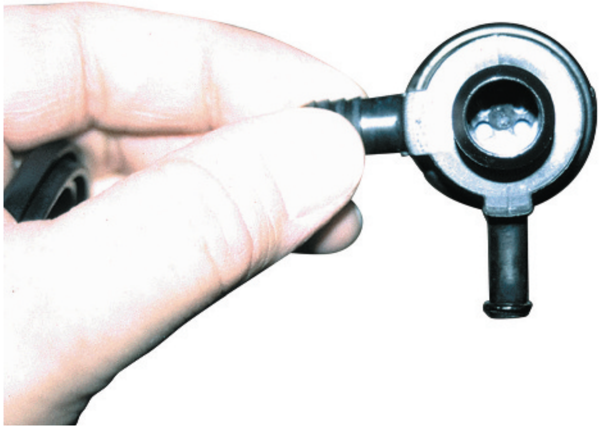
VACUUM CHECK VALVE

All vacuum boosters use a one-way vacuum check valve. This valve allows air to flow in only one direction—from the booster toward the engine. This valve prevents loss of vacuum when the engine stops. Without this check valve, the vacuum stored in the vacuum booster would simply be lost through the hose and intake manifold of the engine. ● **SEE FIGURE 104–7**.

CAUTION: Sometimes an engine backfire can destroy or blow the vacuum check valve out of the booster housing. If this occurs, all power assist will be lost and a much greater-than-normal force must be exerted on the brake pedal to stop the vehicle. Be sure to repair the cause of the backfire before replacing the damaged or missing check valve. Normal causes of backfire include an excessively lean air–fuel ratio or incorrect firing order or ignition timing.



(a)



(b)

FIGURE 104–7 (a) Many vacuum brake booster check valves are located where the vacuum hose from the engine (vacuum source) attaches to the vacuum booster. (b) This one-way valve prevents the loss of vacuum when the engine is off. The diaphragm inside allows air to flow in one direction only.

VACUUM BRAKE BOOSTER OPERATION

A vacuum power-brake booster contains a rubber diaphragm(s) connected to the brake pedal at one end and to the master cylinder at the other end. When the brakes are off or released, there is equal vacuum on both sides of the diaphragm.

The vacuum power unit contains the power-piston assembly, which houses the control valve and reaction mechanism and the power-piston return spring. The control valve is composed of the air valve (valve plunger), the floating control-valve assembly, and the pushrod. The reaction mechanism consists of a hydraulic piston reaction plate and a series of reaction levers. An air filter, air silencer, and filter retainer are assembled around the valve operating rod, filling the cavity inside the hub of the power piston. The pushrod that operates the air valve projects out of the end. ● **SEE FIGURE 104–8**.

RELEASED-POSITION OPERATION At the released position (brake pedal up), the air valve is seated on the floating control valve, which shuts off the air. The floating control valve is held away from the valve seat in the power-piston insert. Vacuum from the engine is present in the space on both sides of the power piston. Any air in the system is drawn through a small passage in the power piston, over the seat in the power-piston insert, and through a passage in the power-piston insert. There is a vacuum on both sides of the power piston, and it is held against the rear of the housing by the power-piston return spring. At rest, the hydraulic reaction plate is held against the reaction retainer.

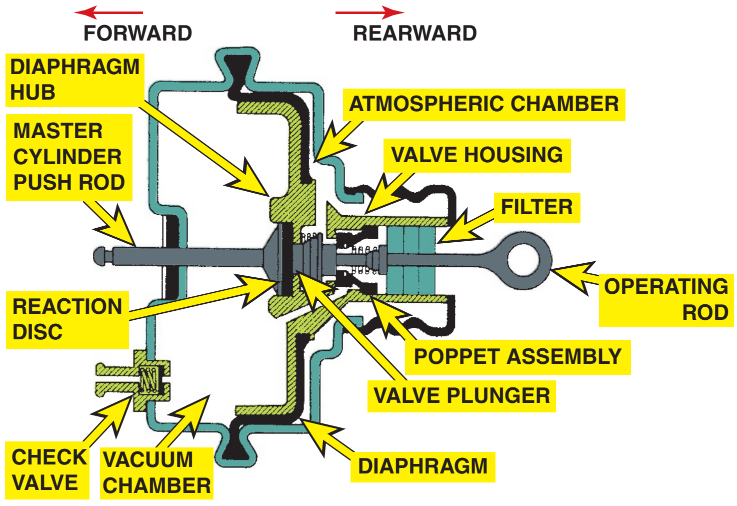


FIGURE 104–8 Cross-sectional view of a typical vacuum brake booster assembly.

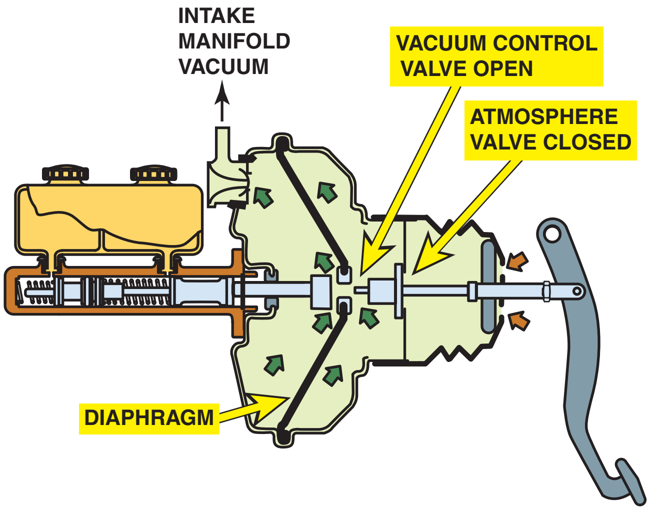

FIGURE 104–9 In the release position (brake pedal up), the vacuum is directed to both sides of the diaphragm.

The air-valve spring holds the reaction lever against the hydraulic reaction plate and holds the air valve against its stop in the tube of the power piston. The floating control-valve assembly is held against the air-valve seat by the floating control-valve spring. ● **SEE FIGURE 104–9**.

APPLIED-POSITION OPERATION

As the brake pedal is depressed, the floating control valve is moved toward its seat in the power piston, away from the rear of the booster. The smaller air valve spring causes the air valve to stretch out toward the retreating floating control valve until it bottoms out on the lip of the power piston's vacuum passage. This closes off the vacuum supply to the rear section of the housing. Since the floating control valve travels farther than the sealing end of the air valve, atmospheric air is allowed to enter between the air valve and the floating control valve pressurizing the rear section of the housing. At this point, the rear section of the housing is pressurized and the front section is under vacuum. Atmospheric pressure can then force the power piston forward.

NOTE: This movement of air into the rear chamber of the brake booster may be heard inside the vehicle as a hissing noise. The loudness of this airflow varies from vehicle to vehicle and should be considered normal.

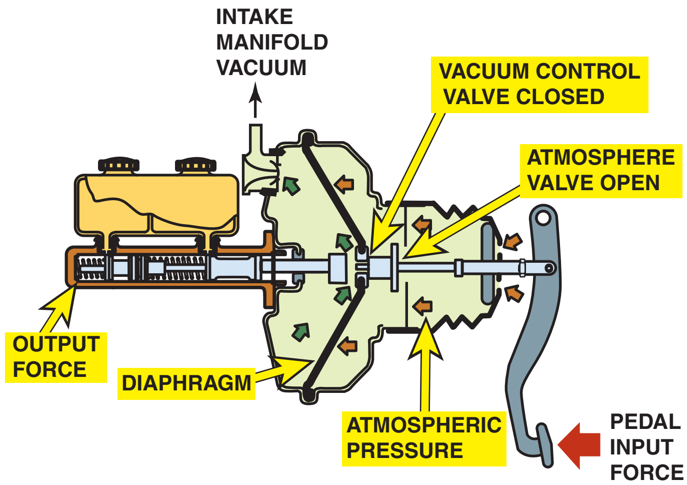

FIGURE 104–10 Simplified diagram of a vacuum brake booster in the apply position. Notice that the atmospheric valve is open and air pressure is being applied to the diaphragm.

As the power piston travels forward, the pushrod pushes against the hydraulic reaction plate in the master cylinder, pushing the master cylinder primary and secondary pistons forward. As back-pressure builds up on the end of the master cylinder piston, the floating control valve is pushed back off of its seat in the power piston, applying back-pressure to the brake pedal. The power-piston return spring also generates some brake pedal force. All in all, approximately 30% of the brake load is applied back to the brake pedal. This gives the driver a feel that is proportional to the degree of brake application. ● **SEE FIGURE 104–10**.

HOLD-POSITION OPERATION

When the desired brake pedal force is reached and there is balance between the opposing forces of the brake pedal and the master cylinder, the power piston moves forward "around" the floating control valve and reaction disc until the air valve sealing end "catches up" with the floating control valve. At this point, the air valve is once again sealed against the floating control valve and is no longer blocking the vacuum passage in the power piston. The floating control valve is again held away from its seat. Vacuum once again is present on both sides of the diaphragm and power piston. The status of the booster is almost exactly as it was in the released state except that the positions of the power piston and subsequently the master cylinder pistons are farther forward. Brake pedal force is keeping the power piston in its position. If additional braking is required (brake pedal pushed farther), the floating control valve moves away from the air valve permitting the power of atmospheric pressure to push the power piston and master cylinder pistons forward. If the pedal is released, since vacuum is then present on both sides of the diaphragm, the power-piston return spring moves the power piston to its released state. ● **SEE FIGURE 104–11**.

VACUUM-FAILURE MODE

In case of vacuum source interruption, the brake operates as a standard brake as follows: As the pedal is pushed down, the operating rod forces the floating control valve against the power piston and reaction disc. This force is then applied to the pushrod and subsequently the hydraulic reaction plate fastened to the master cylinder piston rod, which applies pressure in the master cylinder. For safety in the event of a stalled engine and a loss of vacuum, a power brake booster should have adequate storage of vacuum for several power-assisted stops.

TECH TIP

A Low, Soft Brake Pedal Is Not a Power Booster Problem

Some service technicians tend to blame the power brake booster if the vehicle has a low, soft brake pedal. A defective power brake booster causes a hard brake pedal, not a soft brake pedal. A soft or spongy brake pedal is usually caused by air being trapped somewhere in the hydraulic system.

Many times, the technician has bled the system and, therefore, thinks that the system is free of any trapped air. According to remanufacturers of master cylinders and power brake boosters, most of the returned parts under warranty are not defective. Incorrect or improper bleeding procedures account for much of the problem.

DUAL- (TANDEM-) DIAPHRAGM VACUUM BOOSTERS

To provide power assist, air pressure must work against a rubber diaphragm. The larger the area of the diaphragm, the more force can be exerted. The usual method of increasing the area of the vacuum diaphragm was to increase the diameter of the vacuum booster. However, a larger vacuum booster took up too much room under the hood of many vehicles. Instead of increasing the diameter, vacuum booster manufacturers used two smaller-diameter diaphragms and placed one in front of the other. These designs increased the total area without increasing the physical diameter of the booster. This style is called a **dual-diaphragm** or **tandem-diaphragm vacuum booster**. ● **SEE FIGURE 104–12**.

BRAKE ASSIST SYSTEM

PURPOSE AND FUNCTION Some vehicles are equipped with a **brake assist system (BAS)** that applies the brakes with maximum force if the system detects that the driver is making a panic stop. Tests performed by brake engineers have indicated that it is normal for a person to first apply the brakes rapidly during a panic situation. However, it was also found that the driver would tend to reduce the force applied to the brake pedal. As a result, the vehicle did not brake with the maximum effort.

OPERATION The brake assist system opens an air valve on the rear part of the vacuum booster assembly. As a result, more air at atmospheric pressure can flow into the rear chamber of the vacuum booster, thereby increasing the force applied to the master cylinder. The BAS function works with the electronic stability control (ESC) system to ensure maximum braking efficiency during evasive or emergency situations.

If the speed of the brake pedal application exceeds a predetermined limit as determined by the brake pedal travel sensor, the ABS controller energizes the BAS solenoid valve. When the solenoid valve opens, additional air at atmospheric pressure enters the driver's side of the booster. The additional pressure applies the brakes faster and with more force. The BAS solenoid is deenergized when the brake pedal is released and normal braking returns. ● **SEE FIGURES 104–13 AND 104–14**.

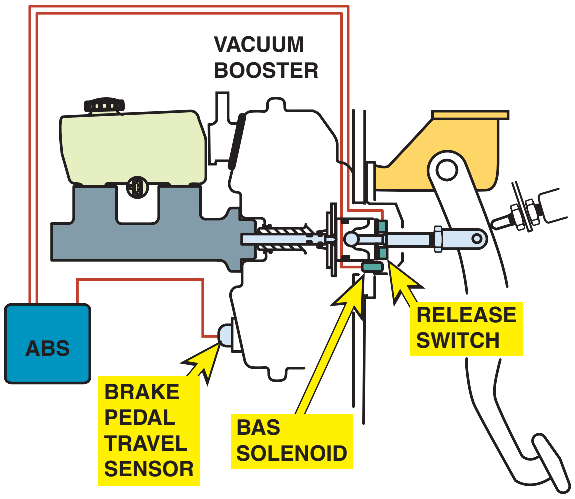

FIGURE 104–13 A typical brake assist system uses a brake pedal travel sensor and a BAS solenoid to apply the brakes during a panic condition.

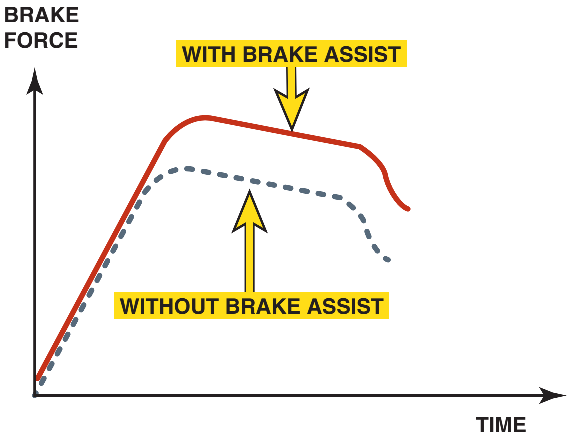

FIGURE 104–14 When the brake assist function operates, the brake force is much higher than normal.

VACUUM BOOSTER OPERATION TEST

With the engine "off," apply the brakes several times to deplete the vacuum. With your foot on the brake pedal, start the engine. The brake pedal *should* drop. If the brake pedal does *not* drop, check for proper vacuum source to the booster. There should be at least 15 in. Hg of vacuum at the booster for proper operation. If there is proper vacuum, repair or replacement of the power booster is required.

VACUUM BOOSTER LEAK TEST

To test if the vacuum booster can hold a vacuum, perform the following steps:

STEP 1 Operate the engine to build up a vacuum in the booster, then turn the engine off.

STEP 2 Wait for one minute.

STEP 3 Depress the brake pedal several times. There should be two or more power-assisted brake applications.

If applications are not power assisted, either the vacuum check valve or the booster is leaking. To test the check valve, remove the valve from the booster and blow through the check valve. If air passes through, the valve is defective and must be replaced. If the check valve is okay, the vacuum booster is leaking and should be repaired or replaced based on the manufacturer's recommendations.

HYDRAULIC SYSTEM LEAK TEST

An internal or external hydraulic leak can also cause a brake system problem. To test if the hydraulic system (and not the booster) is leaking, depress and release the brake pedal (service brakes) several times. This should deplete any residual power assist. On some ABS units, this may require depressing the brake pedal 20 or more times.

After depleting the power-assist unit, depress and then hold the brake pedal depressed with medium force (20 to 35 lb or 88 to 154 N). The brake pedal should *not* fall away. If the pedal falls, the hydraulic brake system is leaking. Check for external leakage at wheel cylinders, calipers, hydraulic lines, and hoses. If there is no external leak, there may be an internal leak inside the master cylinder. Repair or replace components as needed to correct the leakage.

PUSHROD CLEARANCE ADJUSTMENT

Whenever the vacuum brake booster or the master cylinder is replaced, the pushrod length should be checked. The length of the pushrod must match correctly with the master cylinder. ● **SEE FIGURE 104–15**.

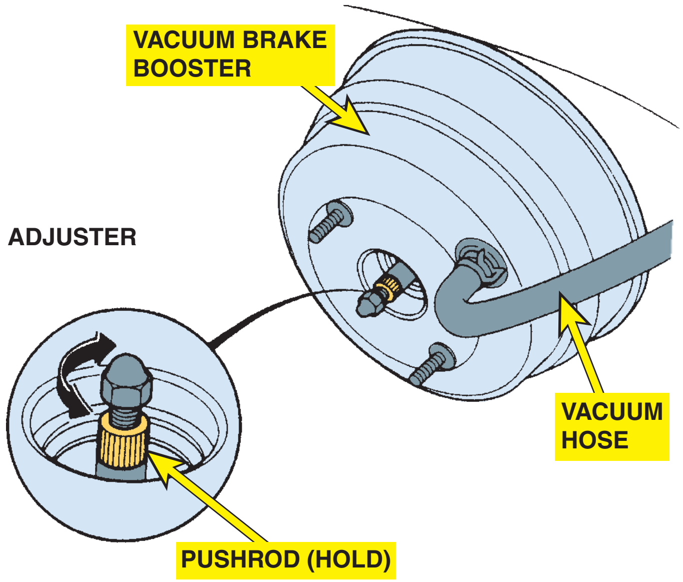

FIGURE 104–15 Typical adjustable pushrod. This adjustment is critical for the proper operation of the braking system. If the pushrod is too long, the brakes may be partially applied during driving. If the rod is too short, the brake pedal may have to be depressed farther down before the brakes start to work.

If the pushrod is too long and the master cylinder is installed, the rod may be applying a force on the primary piston of the master cylinder even though the brake pedal is not applied. This can cause the brakes to overheat, causing the brake fluid to boil. If the brake fluid boils, a total loss of braking force can occur. Obviously, this pushrod clearance check and adjustment is very important. A gauge is often used to measure the position of the master cylinder piston, and then the other end of the gauge is used to determine the proper pushrod clearance. ● **SEE FIGURE 104–16**.

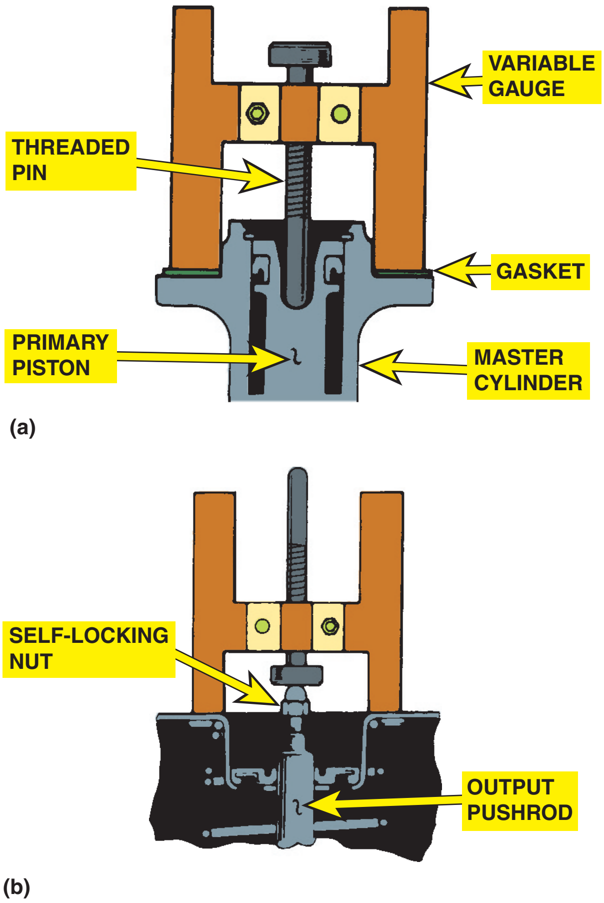

FIGURE 104–16 Typical vacuum brake booster pushrod gauging tool. (a) The tool is first placed against the mounting flange of the master cylinder and the depth of the piston determined. (b) The gauge is then turned upside down and used to gauge the pushrod length. Some vacuum brake boosters do not use adjustable pushrods. If found to be the incorrect length, a replacement pushrod of the correct length should be installed.

FREQUENTLY ASKED QUESTION

What Is Supplemental Brake Assist?

Supplemental brake assist (SBA) is a motor-driven vacuum pump that can supplement engine vacuum to the vacuum brake booster. This unit is used on some General Motors vehicles. When a vehicle is driven under a heavy load, engine vacuum is low. To meet the brake standards, some vehicles are equipped with the brake assist system that consists of the following components:

- A pressure sensor that is used to measure the vacuum in the vacuum booster.
- An intake manifold check valve that is used to prevent vacuum from escaping the vacuum boost.
- A motor-driven vacuum pump.

The vacuum pump motor will start and run if the pressure sensor detects the vacuum in the booster is below 7 in. Hg and will shut off after the vacuum level increases to 9 in. Hg. ● **SEE FIGURE 104–17**.

HYDRO-BOOST HYDRAULIC BRAKE BOOSTER

PURPOSE Hydro-Boost is a hydraulically operated power-assist unit built by Bendix. The Hydro-Boost system uses the pressurized hydraulic fluid from the vehicle's power steering pump as a power source rather than using engine vacuum as is used with vacuum boosters. ● **SEE FIGURE 104–18**.

The Hydro-Boost unit is used on vehicles that lack enough engine vacuum, such as turbocharged or diesel engine vehicles. During operation, diesel engines do not produce vacuum in the intake manifold. As a result, diesel engines must use accessory engine-driven vacuum pumps to operate vacuum accessories. Turbocharged and supercharged engines do not create engine vacuum during periods of acceleration. Even though vacuum is available when the engine is decelerating, some vehicle manufacturers elect to install a Hydro-Boost system rather than equip the vehicle with an accessory engine-driven vacuum pump.

SUPPLEMENTAL BRAKE ASSIST PUMP MOTOR

FIGURE 104–17 The supplemental brake assist (BAS) pump mounts on the brake booster housing.

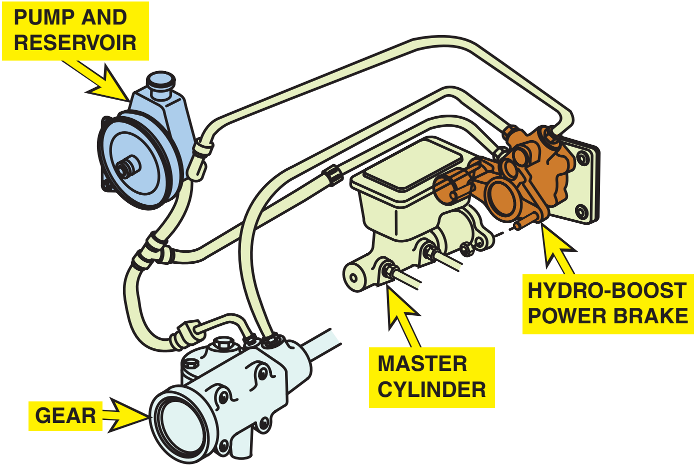

FIGURE 104–18 Hydro-Boost unit attaches between the bulkhead and the master cylinder and is powered by the power steering pump.

OPERATION Fluid pressure from the power steering pump enters the unit and is directed by a spool valve. ● **SEE FIGURE 104–19**. When the brake pedal is depressed, the lever and primary valve are moved. The valve closes off the return port, causing pressure to build in the boost pressure chamber. The hydraulic pressure pushes on the power piston, which then applies force to the output rod that connects to the master cylinder piston. In the event of a power steering pump failure, power assist is still available for several brake applications.

DIAGNOSIS The power source for Hydro-Boost units comes from the power steering pump. The first step of troubleshooting is to perform a thorough visual inspection, including the following:

1. Checking for proper power steering fluid level
2. Checking for leaks from the unit or power steering pump
3. Checking the condition and tightness of the power steering drive belt
4. Checking for proper operation of the base brake system

After checking all of the visual components, check for proper pressure and volume from the power steering pump using a power steering pump tester, as shown in ● **FIGURES 104–20 AND 104–21**.

The pump should be capable of producing a minimum of 2 gallons (7.5 L) with a maximum pressure of 150 PSI (1,000 kPa) with the steering in the straight-ahead position. With the engine "off," the accumulator should be able to supply a minimum of two power-assisted brake applications.

HYDRO-BOOST FUNCTION TEST With the engine off, apply the brake pedal several times until the accumulator is depleted completely. Depress the service brake pedal and start the engine. The pedal should fall and then push back against the driver's foot.

TECH TIP

The Hydro-Boost Accumulator Test

The accumulator stores hydraulic fluid under pressure to provide a reserve in the event of a failure of the power steering system. The accumulator is designed to provide three or more power-assisted stops with the engine off. ● **SEE FIGURE 104–22**.

If the accumulator fails, it does not hold pressure. To easily check whether the accumulator has lost its charge, simply grasp the accumulator with your hand and try to twist or move it. The accumulator should have so much pressure on it that it should not move or wiggle. If the accumulator moves, it has lost its ability to hold pressure and the Hydro-Boost unit should be replaced.

HYDRO-BOOST SYMPTOM-BASED GUIDE

EXCESSIVE BRAKE PEDAL EFFORT Possible causes for this include the following:

1. Loose or broken power steering pump belt
2. No fluid in the power steering reservoir
3. Leaks in the power steering, booster, or accumulator hoses
4. Leaks at tube fittings, power steering, booster, or accumulator connections
5. External leakage at the accumulator
6. Faulty booster piston seal, causing leakage at the booster flange vent
7. Faulty booster cover seal with leakage between the housing and cover
8. Faulty booster spool plug seal

SLOW BRAKE PEDAL RETURN Possible causes for this include the following:

1. Excessive seal friction in the booster
2. Faulty spool action
3. Broken piston return spring
4. Restriction in the return line from the booster to the pump reservoir
5. Broken spool return spring

GRABBY BRAKES Possible causes for this include the following:

1. Broken spool return spring
2. Faulty spool action caused by contamination in the system

BOOSTER CHATTERS—PEDAL VIBRATES Possible causes for this include the following:

1. Power steering pump belt slipping
2. Low fluid level in the power steering pump reservoir
3. Faulty spool operation caused by contamination in the system

FREQUENTLY ASKED QUESTION

How Does an Electric Power Brake Assembly Work?

The base brakes used on electric vehicle use an electric motor actuator to increase the force applied by the driver to the hydraulic system. An electric vehicle does not have an internal combustion engine and therefore does not have engine vacuum, which is used by most power brake systems used on most vehicles

REVIEW QUESTIONS

1. Describe the purpose and function of the one-way check valve used on vacuum brake booster units.
2. Explain how vacuum is used to assist in applying the brakes.
3. Describe how to perform a vacuum booster leak test and hydraulic system leak test.
4. Explain how a Hydro-Boost system functions.

CHAPTER QUIZ

1. A power brake booster provides which of the following design features?
   - **a.** Reduced stopping distance
   - **b.** Reduced brake pedal effort
   - **c.** High brake pedal effort
   - **d.** A lower brake pedal position
2. The proper operation of a vacuum brake booster requires that the engine be capable of supplying at least ___________.
   - **a.** 15 in. Hg vacuum
   - **b.** 17 in. Hg vacuum
   - **c.** 19 in. Hg vacuum
   - **d.** 21 in. Hg vacuum
3. A defective vacuum brake booster will cause a ___________.
   - **a.** hard brake pedal
   - **b.** soft (spongy) brake pedal
   - **c.** low brake pedal
   - **d.** slight hiss noise when the brake pedal is depressed
4. A brake pedal feels spongy when depressed. Technician A says that a defective hydraulic brake booster could be the cause. Technician B says that a defective vacuum brake booster could be the cause. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
5. Two technicians are discussing vacuum brake boosters. Technician A says that a low, soft brake pedal is an indication of a defective booster. Technician B says that there should be at least two power-assisted brake applications after the engine stops running. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
6. Technician A says that to check the operation of a vacuum brake booster, the brake pedal should be depressed until the assist is depleted and then start the engine. Technician B says that the brake pedal should drop when the engine starts, if the booster is okay. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
7. Which of these could be caused by an improperly adjusted booster pushrod?
   - **a.** Brakes to overheat
   - **b.** A soft pedal
   - **c.** A low pedal
   - **d.** None of these
8. An accumulator such as that used on hydraulic brake boosters ___________.
   - **a.** reduces brake pedal noise
   - **b.** provides higher force being fed back to the driver's foot
   - **c.** provides a reserve in the event of a failure
   - **d.** works against engine vacuum
9. The typical vacuum booster has a power chamber separated into two smaller chambers by a ___________.
   - **a.** gasket
   - **b.** check valve
   - **c.** wire mesh
   - **d.** flexible diaphragm
10. When the brakes are released, the booster has ___________ on both sides of the power piston.
    - **a.** brake fluid
    - **b.** vacuum
    - **c.** atmospheric pressure
    - **d.** None of the above

ANTILOCK BRAKE SYSTEM

PURPOSE AND FUNCTION **Antilock brake systems (ABS)** help prevent the wheels from locking during sudden braking, especially on slippery surfaces.

- This helps the driver maintain control.
- Antilock brakes increase safety because they eliminate wheel/tire lockup and minimize the danger of skidding, allowing the vehicle to stop in a straight line.
- ABS also allows the driver to maintain steering control during heavy braking so the vehicle can be steered to avoid an obstacle or another vehicle.
- ABS can improve braking when road conditions are less than ideal, as when making a sudden panic stop or when braking on a wet or slick road. ABS does this by monitoring the relative speed of the wheels to one another. It uses this information to modulate brake pressure as needed to control slippage and maintain traction when the brakes are applied.

ABS AND TIRE TRACTION Preventing brake lockup is important because of the adverse effect a locked wheel has on tire traction. The brakes slow the rotation of the wheels, but it is the friction between the tire and road that stops the vehicle and allows it to be steered. If tire traction is reduced, stopping distances increase and the directional stability of the vehicle suffers. Traction is defined in terms of **tire slip**, which is the difference between the actual speed and the rate at which the tire tread moves across the road.

- A free-rolling wheel has nearly zero tire slip
- A locked wheel has 100% tire slip. ● **SEE FIGURE 105–1**.

When the brakes are applied, the rotational speed of the wheel drops, and tire slip increases because the tread moves across the road slower than the actual vehicle speed. This slip creates friction that converts kinetic energy into braking and cornering force.

TIRE SLIP AND BRAKING DISTANCE On dry or wet pavement, maximum braking traction occurs when tire slip is held between approximately 15% and 25%. ● **SEE FIGURE 105–2**.

On snow- or ice-covered pavement, the optimum slip range is 20% to 50%. In each case, if tire slip increases beyond these levels, the amount of traction decreases. A skidding tire with 100% slip provides 20% to 30% less braking traction on dry pavement, and this is generally true on slippery roads as well. In nearly all cases, the shortest stopping distances are obtained when the brakes are applied with just enough force to keep the tire slip in the range where traction is greatest.

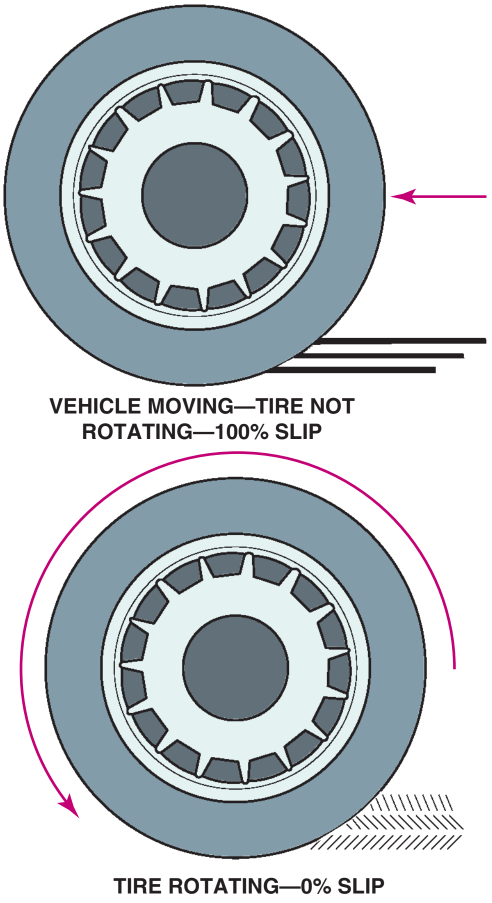

FIGURE 105–1 Maximum braking traction occurs when tire slip is between 10% and 20%. A rotating tire has 0% slip and a locked-up wheel has 100% slip.

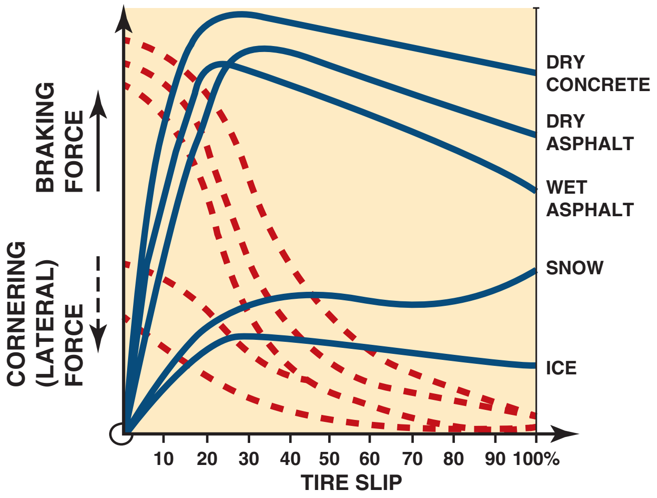

FIGURE 105–2 Traction is determined by pavement conditions and tire slip.

TIRE SLIP AND VEHICLE STABILITY A tire's contact patch with the road can provide only a certain amount of traction. When a vehicle is stopped in a straight line, nearly all of the available traction can be used to provide braking force. Only a small amount of traction is required to generate lateral force that keeps the vehicle traveling in a straight line. However, if a vehicle has to stop and turn at the same time, the available traction must be *divided* to provide both cornering (lateral) and braking force.

No tire can provide full cornering power and full braking power at the same time. When a brake is locked and the tire has 100% slip, all of the available traction is used for braking, and none is left for steering. As a result, a skidding tire follows the path of least resistance. This means that if the rear brakes lock, the back end of the vehicle will tend to swing around toward the front causing a spin. If the front brakes lock, steering control will be lost and the vehicle will slide forward in a straight line until the brakes are released to again make traction available for steering.

TECH TIP

Tire "Chirp" Noise during Hard Braking Is Normal

Sometimes customers state that they do not think that their antilock brake system (ABS) is working correctly because they heard the tires making noise (chirping sound) during hard braking. This is normal as the tires slip about 20% during an ABS stop.

ABS LIMITATIONS There are two situations in which an antilock brake system will *not* provide the shortest stopping distances.

1. The first involves straight stops made on smooth, dry pavement by an *expert* driver. Under these conditions, a skilled driver can hold the tires consistently closer to the ideal slip rate than the ABS can. ● **SEE FIGURE 105–3**.

   This is possible because current antilock brake systems may allow the amount of tire slip to drop as low as 5%, which is somewhat below the point where maximum tire traction is achieved. However, for the average driver, or under less-than-ideal conditions, antilock brakes will almost always stop the vehicle in a shorter distance.
2. The other situation in which antilock brakes will not provide the shortest stops is when braking on loose gravel or dirt, or in deep, fluffy snow. Under these conditions, a locked wheel will stop the vehicle faster because loose debris builds up and forms a wedge in front of the tire that helps stop the vehicle. ● **SEE FIGURE 105–4**.

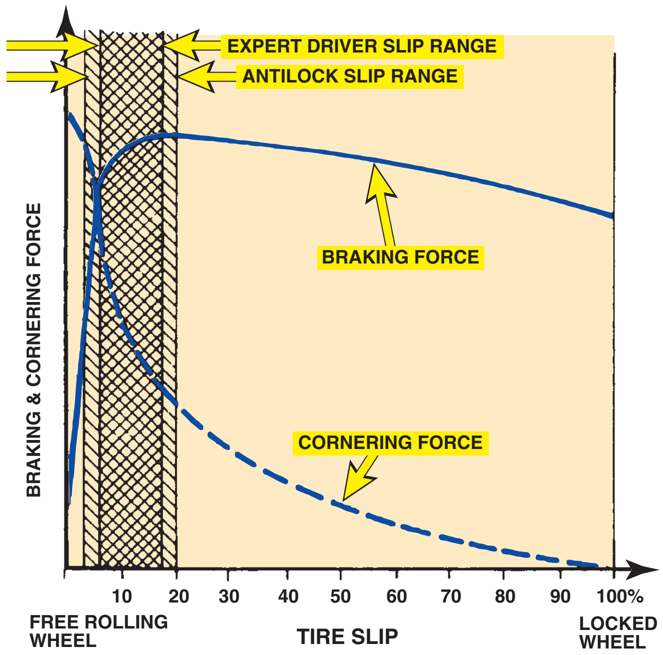

FIGURE 105–3 A good driver can control tire slip more accurately than an ABS if the vehicle is traveling on a smooth, dry road surface.

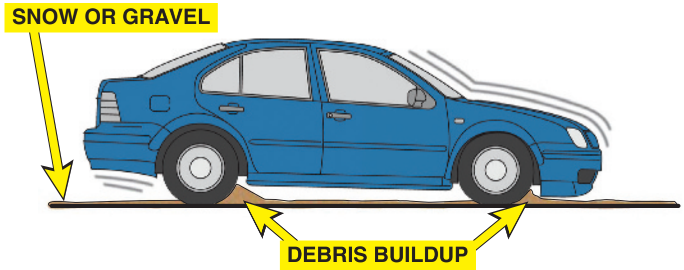

FIGURE 105–4 A wedge of gravel or snow in the front of a locked wheel can help stop a vehicle faster than would occur if the wheel brakes were pulsed on and off by an antilock brake system.

An antilock brake system will prevent this wedge from forming, so some vehicles with antilock brakes have a switch on the instrument panel that allows the system to be deactivated when driving on these kinds of road surfaces.

ABS AND THE LAWS OF PHYSICS No ABS can overcome the laws of physics. The weight and speed of a moving vehicle give it a great deal of kinetic energy and only so much of that energy can be converted into braking or cornering force at any given time.

- The limiting factor in this conversion is the traction between the tires and road. Although a vehicle with four-wheel antilock brakes will stop in very nearly the shortest possible distance, this will still not prevent an accident if the brakes are applied too late to bring the vehicle to a complete stop before impact. However, because steering control is retained with four-wheel antilock brakes, it may be possible to drive the vehicle around a potential accident while in the process of braking.
- Another situation where antilock brakes cannot defy the laws of physics occurs when a vehicle enters a corner traveling faster than it is physically possible to negotiate the turn. In this situation, antilock brakes will not prevent the vehicle from leaving the road. However, they will allow the vehicle to be slowed and steered in the process, thus lessening the severity of the eventual impact. ● **SEE FIGURE 105–5**.

ABS PARTS INVOLVED

WHEEL SPEED SENSOR INPUT All ABS control tire slip by monitoring the relative deceleration rates of the wheels during braking. Wheel speed is monitored by wheel speed sensors.

- If one wheel starts to slow at a faster rate than the others, or at a faster rate than that which is programmed in the antilock control module, it indicates a wheel is starting to slip and is in danger of losing traction and locking.
- The ABS responds by momentarily reducing hydraulic pressure to the brake on the affected wheel or wheels. This allows the wheel to speed up momentarily so it can regain traction. As traction is regained, brake pressure is reapplied to again slow the wheel.
- The cycle is repeated over and over until the vehicle stops or until the driver eases pressure on the brake pedal.

CONTROL MODULE The control module receives wheel speed information from the wheel speed sensors (WSS) and then sends a voltage signal to the control solenoids which then controls brake fluid pressure at the wheel brakes. The ABS electronic control module is a digital microprocessor that uses inputs from its various sensors to regulate hydraulic pressure during braking to prevent wheel lockup. The ABS controller may be referred to as:

- Electronic brake control module (EBCM)
- Electronic brake module (EBM)
- Controller antilock brakes (CAB)

The module may be located on the hydraulic modulator assembly (as it is on many of the newer compact ABS), or it may be located elsewhere in the vehicle, such as the trunk, passenger compartment, or under the hood.

VALVES Electrically operated solenoid valves are used to hold, release, and reapply hydraulic pressure to the brakes. This produces a pulsating effect, which can be felt in the brake pedal during hard braking. The rapid modulation of brake pressure in a given brake circuit reduces the braking load on the affected wheel and allows it to regain traction to prevent lockup. The effect is much the same as pumping the brakes, except that the ABS does it automatically for each brake circuit, and at speeds that would be humanly impossible—up to 20 times per second depending on the system (some cycle faster than others). ● **SEE FIGURE 105–6**.

FREQUENTLY ASKED QUESTION

When Was ABS First Used?

Antilock brake systems were first used in the 1950s on aircraft and then first used on a 1970 Lincoln Continental using a rear-wheel braking system called "Sure Track" as an option. Also in 1970, General Motors Corporation offered a rear-wheel antilock brake system on selected rear-wheel-drive vehicles, which was called "Track Master" made by AC Electronics Division of GM. In 1971, Chrysler Imperial offered a three-channel system that used four wheel speed sensors built by Bendix Corporation, called "Sure Brake" by Chrysler.

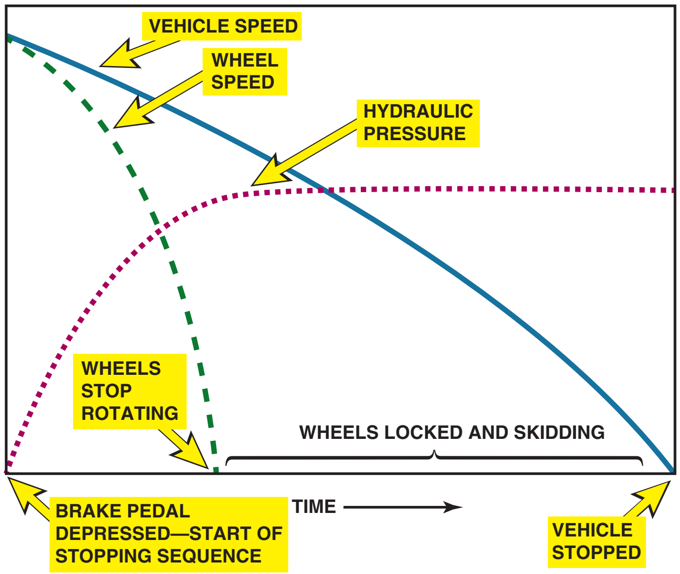

FIGURE 105–6 A typical stop on a slippery road surface without antilock brakes. Notice that the wheels stopped rotating and skidded until the vehicle finally came to a stop.

Once the rate of deceleration for the affected wheel catches up with the others, normal braking function and pressure resume, and antilock reverts to a passive mode.

PUMP A pump is used in most antilock systems to restore brake fluid pressure after the valves have released the pressure in an effort to control wheel slippage.

ABS CHANNELS

All ABS keep track of wheel deceleration rates with wheel speed sensors. The various ABS use a different number of sensors, depending on how the system is configured. These include

- single-channel systems
- three-channel systems
- four-channel systems

● **SEE FIGURE 105–7**.

SINGLE-CHANNEL SYSTEMS Most of the early antilock brake systems were used to control the rear brakes only. This type of system was called single-channel ABS. The single-channel rear-wheel only ABS is used on older rear-wheel-drive pickups and vans.

- Ford version is called Rear Antilock Brake System (RABS)
- General Motors and Chrysler version is called Rear Wheel Antilock (RWAL)—pronounced "R wall."

The front wheels have no speed sensors, and only a single speed sensor mounted in the differential or transmission is used for both rear wheels. Rear-wheel antilock systems are typically used on applications where vehicle loading can affect rear-wheel traction, which is why it is used on pickup trucks and vans. Because the rear-wheel antilock systems have only a single channel, they are much less complex and costly than their multichannel, four-wheel counterparts.

THREE-CHANNEL ABS SYSTEMS Some four-wheel ABS have a separate wheel speed sensor for each front wheel but use a common speed sensor for both rear wheels. These are called "three-channel" systems. The rear wheel speed sensor is mounted in either the differential or the transmission. The sensor reads the combined or average speed of both rear wheels. This type of setup saves the cost for an additional sensor and reduces the complexity of the system by allowing both rear wheels to be controlled at the same time which is called the **select low principle**. Three-channel systems were the most common type of ABS setup used on early rear-wheel-drive applications.

FOUR-CHANNEL ABS On some applications, each wheel is equipped with its own speed sensor. This type of arrangement is called a "four-wheel, four-channel" system since each wheel speed sensor provides input for a separate hydraulic control circuit or "channel." The term *channel* always refers to the number of separate or individually controlled ABS hydraulic circuits in an ABS, not the number of wheel speed sensor electrical circuits.

NOTE: For vehicle stability systems to function, there has to be four wheel speed sensors and four channels so the hydraulic control unit can pulse individual wheel brakes to help achieve vehicle stability.

ABS OPERATION ABS have a conventional brake master cylinder and vacuum power booster with a separate hydraulic modulator unit. Some also have an electric pump for ABS braking (to reapply pressure during the ABS hold–release–reapply cycle), but do not use the pumps for normal power assist. Nonintegral ABS are the most common type of ABS because of their lower cost and simplicity. ● **SEE FIGURE 105–8**.

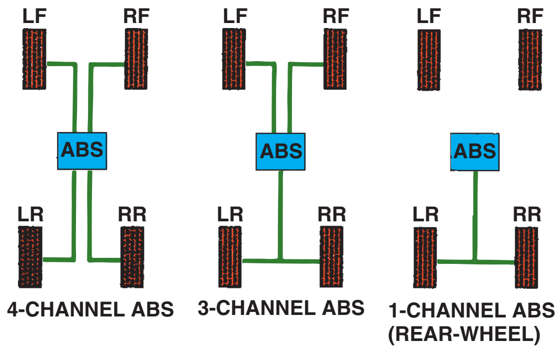

FIGURE 105–7 ABS configuration includes four-channel, three-channel, and single-channel systems.

ABS CONTROLLER INPUTS AND OUTPUTS

INPUTS The key inputs for the ABS control module come from the wheel speed sensors and the brake pedal switch. The brake pedal switch signals the control module when the brakes are being applied, which causes it to go from a "standby" mode to an active mode. At the same time, the wheel speed sensors provide

information about what is happening to the wheels while the brakes are being applied.

NOTE: A fault with the brake switch will not prevent ABS operation.

The brake switch allows the controller to react faster to an ABS event. The signals being sent to the ABS controller (module) include the following:

- Wheel speed—from wheel speed sensors
- Brake on/off—from the brake pedal switch
- Steering wheel position—used for electronic stability control
- Yaw and accelerometer sensors—used for electronic stability control system

OUTPUTS The ABS controller (module) controls the following components:

- System relay
- Inlet valves
- Outlet valve
- Pump motor
- ABS warning lamp (amber ABS dash light)

● **SEE FIGURE 105–9**.

MODULE OPERATION If the control module detects a difference in the deceleration rate between one or more wheels when braking, or if the overall rate of deceleration is too fast and exceeds the limits programmed into the control module, it triggers the ABS control module to momentarily take over. The control module cycles the solenoid valves in the modulator assembly to pulsate hydraulic pressure in the affected brake circuit (or circuits) until wheel speed sensor information indicates that the deceleration rates have returned to normal and braking is under control. Normal braking resumes. When the brake pedal is released or when the vehicle comes to a stop, the control module returns to a standby mode until it is again needed.

ABS WARNING LAMP Every ABS has an amber indicator lamp on the instrument panel that warns the driver when a problem occurs within the ABS.

- On most applications, the ABS is disabled if the ABS warning light comes on and remains on. This should have no effect on normal braking, unless the red brake warning lamp is also on which could indicate a base brake hydraulic fault.

WHEEL SPEED SENSORS

PURPOSE AND FUNCTION The purpose and function of **wheel speed sensors**, abbreviated WSS, is to monitor the speed of the wheels. The antilock brake controller uses the data from the wheel speed sensors to control the solenoids (valves) in the hydraulic brake control module and controls how fast the wheels are slowing during a stop.

WHEEL SPEED SENSOR LOCATIONS The sensor itself may be mounted on or in

- steering knuckle
- wheel hub
- brake backing plate
- transmission tail shaft housing
- transfer case
- differential housing
- integral part of the wheel bearing and hub assembly.

The sensor (reluctor) ring may be mounted on the

- axle hub behind the brake rotors
- brake rotors or drums
- outside of the outboard constant velocity joints on a front-wheel-drive vehicle
- transmission tail shaft housing
- inside the differential on the ring gear or pinion gear shaft. ● **SEE FIGURE 105–10**.

PASSIVE WHEEL SPEED SENSORS A **passive wheel speed sensor** generates its own output signal and can operate without an outside voltage being applied. Passive wheel speed sensors are often called **variable reluctance (VR)**-type sensor, which uses a magnetic core surrounded by coil windings. The sensor is mounted at a specific gap from a notch-and-tooth reluctor ring. ● **SEE FIGURE 105–11**.

- As the wheel turns, teeth on the reluctor (sensor) ring move through the pickup's magnetic field.
- As the gap between the notch and the ring changes with the rotation of the reluctor, the sensor induces an alternating current (AC) voltage in the sensor windings.
- The voltage signal will increase in amplitude with an increase with the speed of the reluctor ring, also called a *tone ring*. A typical passive WSS starts to produce a usable speed signal above 2 MPH (3 km/h).
- The variable-reluctance sensor is a two-wire sensor mounted in the steering knuckle and rear suspension or axle. This reverses the polarity of the magnetic field and induces an alternating current voltage in the sensor windings.
- The number of voltage pulses per second induced in the pickup changes frequency. ● **SEE FIGURE 105–12**.
- The frequency of the signal is therefore proportional to wheel speed. The higher the frequency, the faster the wheel is turning.

The control module then monitors wheel speed by counting the pulses from each of the wheel speed sensors. If the frequency signal from one wheel starts to change abruptly with respect to the others, it tells the module that wheel is starting to lose traction. The module then applies antilock braking if needed to maintain traction.

The major problem with this type of sensor is that the voltage output and frequency are very low at slow speeds and therefore cannot produce accurate wheel speed for ABS and traction control. ● **SEE FIGURE 105–13**.

NOTE: Many vehicles that use a passive type of wheel speed sensor apply a small voltage, usually 2.5 volts, to the wires of the sensor to check for circuit continuity. This bias voltage does not affect the operation of the sensor because the sensor creates an AC voltage output which rides on top of the applied DC voltage and is used only for circuit diagnosis.

ACTIVE WHEEL SPEED SENSORS **Active wheel speed sensors** are called active because they require outside electrical

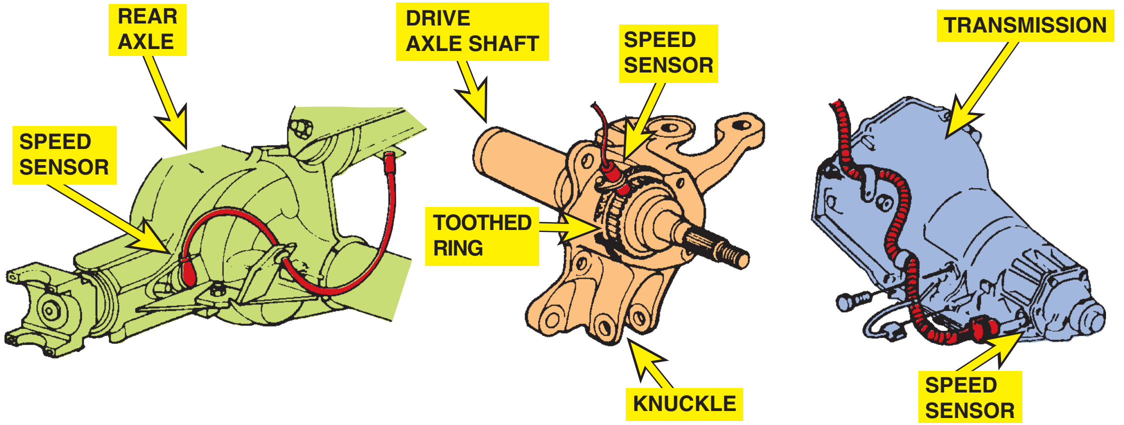

FIGURE 105–10 Wheel speed sensors for the rear wheels may be located on the rear axle, on the transmission, or on the individual wheel knuckle.

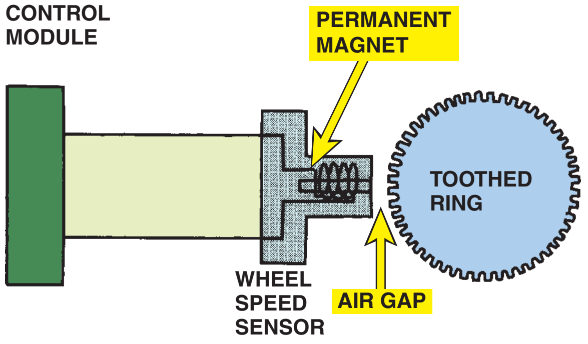

FIGURE 105–11 A schematic of a typical wheel speed sensor.

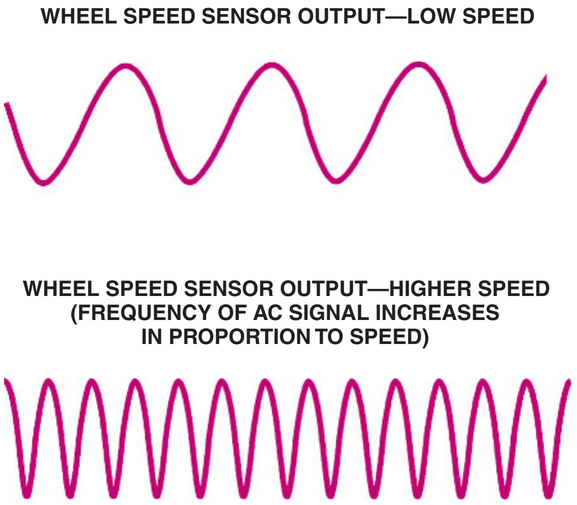

FIGURE 105–12 Wheel speed sensors produce an alternating current (AC) signal with a frequency that varies in proportion to wheel speed.

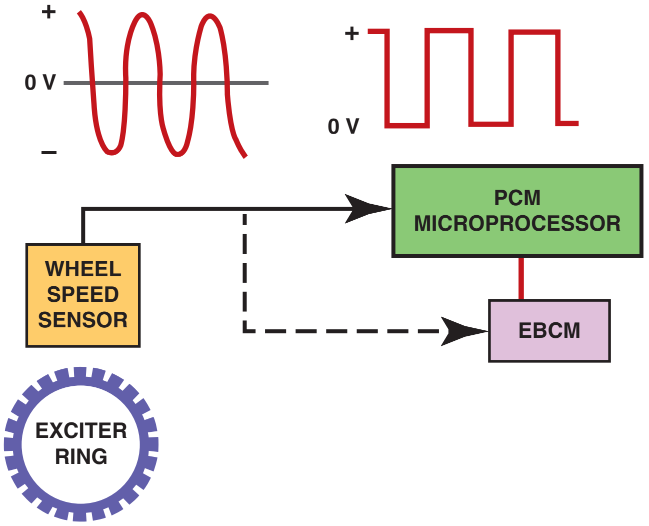

FIGURE 105–13 A typical passive variable-reluctance sensor produces a sine wave (continuously variable) output signal which is then converted to a square wave inside the PCM and/or the electronic brake control module (EBCM).

power to operate. An active WSS is also called a *digital wheel speed sensor* because it generates a digital on and off output signal and is capable of detecting wheel speed as low as 0 MPH (0 km/h). There are two types of active wheel speed sensors:

1. **Hall-effect**—A Hall-effect sensor uses a permanent magnet behind an integrated circuit (IC) chip. The magnetic field penetrates the IC and the toothed wheel. If the toothed wheel is turning, the magnetic field is changing. The IC is measuring the change in the field and is addressing the changes in a rectangle signal. The signal is not dependent on the speed.
2. **Magneto-resistive (MR)**—The most common type of active sensor is the magneto-resistive type, which uses a magneto-resistive circuit to produce a square waveform where the frequency is proportional to the wheel speed.

   A digital wheel speed sensor can also detect direction and can therefore be used by the controller for advanced features such as hill holding. The accuracy of these digital sensors also makes correlation to global positioning used in navigational systems more accurate, especially when the vehicle is being driven at slow speeds.

The typical active wheel speed sensor uses two wires with the ground supplied by the sensor mount:

- A 12-volt supply
- A DC signal from the sensor

The sensor voltage toggles between about 0.8 volt and 1.9 volt.

● **SEE FIGURE 105–14.**

HYDRAULIC MODULATOR ASSEMBLY

PURPOSE AND FUNCTION The modulator valve body is part of the master cylinder assembly in integral antilock systems but separate in nonintegral systems. It contains solenoid valves for each brake unit (in Delphi ABS-VI applications, however, motor-driven valves are used instead of solenoids). The exact number of valves per circuit depends on the ABS and the application. Some use a pair of on–off solenoid valves for each brake circuit, while others use a single valve that can operate in more than one position.

ABS SOLENOID A solenoid consists of a wire coil with a movable core and a return spring. When current from the ABS control module energizes the coil, it pulls on the movable core. Depending on how the solenoid is constructed, this may open or close a valve that is attached to the movable core. When the control current is shut off, the solenoid snaps back to its normal or rest position.

FIGURE 105–15 An ABS three-way solenoid can increase, maintain, or decrease brake pressure to a given brake circuit.

Some solenoids are designed to do more than just switch on or off to open or close a valve. Some pull a valve to an intermediate position when a certain level of current is applied to the coil, then pull the valve to a third position when additional current is provided. ● **SEE FIGURE 105–15.**

This design allows a single solenoid to perform the same functions as two or even three single-position solenoids. The solenoids in the hydraulic modulator assembly are used to open and close passageways between the master cylinder and the individual brake circuits. By opening or closing the modulator valves to which they're attached, brake pressure within any given circuit can be held, released, and reapplied to prevent lockup during hard braking.

ABS CONTROL PRESSURE STAGES The standard ABS control strategy that is used is a three-step cycle:

1. The first step is to hold or isolate the pressure in a given brake circuit by closing an *isolation solenoid* in the modulator assembly. This solenoid is normally electrically and hydraulically opened. When the solenoid is electrically closed, it becomes hydraulically closed, which blocks off the line and prevents any further pressure from the master cylinder reaching the brake. This is called the **pressure holding stage**. ● **SEE FIGURE 105–16.**
2. If the wheel speed sensor continues to indicate the wheel is slowing too quickly and is starting to lock, the same solenoid or a second release solenoid is energized to open a vent port that releases pressure from the brake circuit. ● **SEE FIGURE 105–17.**
3. The fluid is usually routed into a spring-loaded or pressurized storage reservoir (called an accumulator) so it can be reused as needed. Releasing pressure in the brake circuit allows the brake to loosen its grip so the wheel can speed up and regain traction. This is called
   - **pressure reduction stage**
   - **pressure release stage**
   - **pressure decay stage**
   - **pressure dump stage**

   The *pressure reduction solenoid* is normally hydraulically closed and electrically opened.

4. The release and isolation solenoids are then closed and the additional solenoid energized, so pressure can be reapplied to the brake from the master cylinder or accumulator to reapply the brake. This is called the **pressure increase stage**. During this stage, the isolation solenoid is electrically and hydraulically opened. The pressure reduction solenoid is electrically opened and hydraulically closed. ● **SEE FIGURE 105–18.**

The hold–release–reapply cycle repeats as many times as needed until the vehicle either comes to a halt or the driver releases the brake pedal. The speed at which this occurs depends

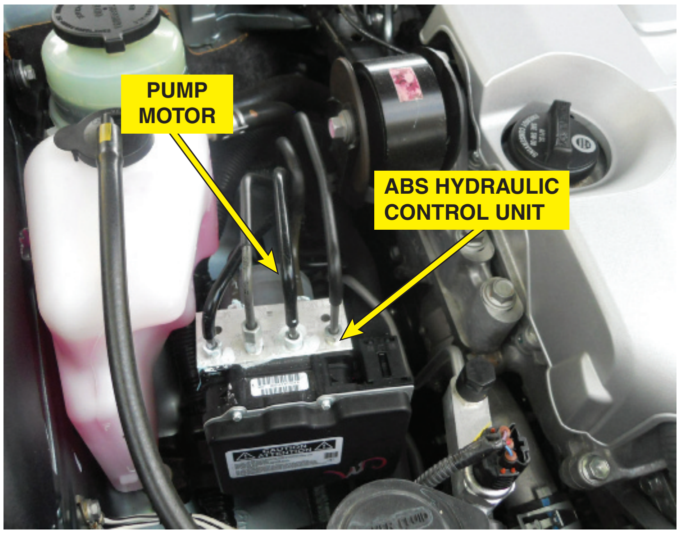
on the particular ABS that is on the vehicle, but can range from a few times per second up to dozens of times per second.

PUMP MOTOR AND ACCUMULATOR

A high-pressure electric pump is used in some ABS to generate power assist for normal braking, as well as the reapplication of brake pressure during ABS braking. ● **SEE FIGURE 105–19**.



PUMP MOTOR
ABS HYDRAULIC CONTROL UNIT

FIGURE 105–19 A typical ABS hydraulic control assembly.

In some systems, it is used only for the reapplication of pressure during ABS braking. The pump motor is energized by a relay, which is switched on and off by the ABS control module. The fluid pressure generated by the pump is stored in the **accumulator**. Some antilock brake systems have more than one accumulator.

- The accumulator on ABS, where the hydraulic modulator is part of the master cylinder assembly, consists of a pressure storage chamber filled with nitrogen gas. A thick rubber diaphragm forms a barrier between the nitrogen gas and brake fluid. As fluid is pumped into the accumulator, it compresses the gas and stores pressure. When the brake pedal is depressed, pressure from the accumulator flows to the master cylinder to provide power assist.
- A pair of pressure switches mounted in the accumulator circuit signals the ABS control module to energize the pump when pressure falls below a preset minimum, then to shut the pump off once pressure is built back up. Should the pump fail (a warning lamp comes on when reserve pressure drops too low), there is usually enough reserve pressure in the accumulator for 10 to 20 power-assisted stops. After that, there is no power assist. The brakes still work, but with greatly increased effort.
- On ABS that have a conventional master cylinder and vacuum booster for power assist, a small accumulator or pair of accumulators may be used as temporary storage reservoirs for brake fluid during the hold–release–reapply cycle. This type of accumulator typically uses a spring-loaded diaphragm rather than a nitrogen-charged chamber to store pressure.

⚠ WARNING

A fully charged accumulator in an old integral ABS system can store up to 2,700 PSI (19,000 kPa) of pressure for power-assist braking and for reapplying the brakes during the hold–release–reapply cycle for antilock braking. This stored pressure represents a potential hazard for a brake technician who is servicing the brakes, so the accumulator should be depressurized prior to doing any type of brake service work by pumping the brake pedal 25 to 40 times with the ignition key off.

TECH TIP

Best to Keep Stock Tire Diameter

Vehicles equipped with antilock brakes are "programmed" to pulse the brakes at just the right rate for maximum braking effectiveness. A larger tire rotates at a slower speed and a smaller-than-normal tire rotates at a faster speed. Therefore, tire size affects the speed and rate of change in speed of the wheels as measured by the wheel speed sensors. While changing tire size will not prevent ABS operation, it will cause less effective braking during hard braking with the ABS activated. Using the smaller spare tire can create such a difference in wheel speed compared with the other wheels that a false wheel speed sensor code may be set and an amber ABS warning lamp on the dash may light. However, most ABS will still function with the spare tire installed, but the braking performance will not be as effective. For best overall performance, always replace tires with the same size and type as specified by the vehicle manufacturer.

NOTE: In nonintegral ABS where an accumulator is used to temporarily hold fluid during the release phase of the hold–release–reapply ABS cycle, the accumulator consists of a spring-loaded diaphragm. This type of accumulator does *not* have to be depressurized prior to performing brake service.

ADVANCED ABS FUNCTIONS

OVERVIEW Much of the same equipment that allows an ABS system to control wheel lockup during braking can be adapted to control other vehicle dynamics. Some of these advanced ABS functions are

- Traction Control
- Stability Control, also called Vehicle Stability Enhancement System (VSES)
- Electronic front/rear proportioning
- Hill start assist
- Tire-pressure monitoring system (TPMS)

TRACTION CONTROL These systems may be called Traction Control (TC), Traction Control System (TCS), or Acceleration Slip Regulation (ASR). Much of the same equipment that allows an ABS system to control wheel lockup during deceleration can be adopted to control wheel spin during acceleration.

STABILITY CONTROL Some vehicles may be equipped with stability control systems (Stabilitrak®), also called Vehicle Stability Enhancement System (VSES), which is a software extension of the ABS control module that senses (using the WSS input) when a vehicle is braking in a turn. The software balances brake forces at wheels (side-to-side) to counteract a yaw movement and improve the vehicle stability while braking in cornering maneuvers. The system is active during all braking—not just during ABS events.

FREQUENTLY ASKED QUESTION

How Much Positive Slip Is Allowed during Rapid Acceleration?

Many electric vehicles are able to accelerate at a rapid rate without wheel spin. According to electric vehicle manufacturer engineers, the electric motor controller is responsible for the torque delivery and it monitors the wheel speed sensor to maintain about a 3% positive slip. This means that there is some slippage but the 3% rate allows the vehicle to accelerate at the fastest possible rate without a loss of traction.

ELECTRONIC PROPORTIONING Electronic front-to-rear proportioning control makes it possible to eliminate the mechanical proportioning valve on the vehicle. This is also called Dynamic Rear Proportioning (DRP) or Electronic Brake Distribution (EBD), depending on the manufacturer. By using EBCM control software and the hydraulic modulator assembly, best front-to-rear brake balance can be maintained at all times.

- As the vehicle decelerates under braking, the ABS/TCS module monitors the wheel speed sensors.
- If rear-wheel speeds show a slightly greater deceleration rate than the front wheels, the electronic brake control module will reduce the rear-wheel brake pressure by commanding the appropriate solenoid valves on and off.

HILL START ASSIST The hill start assist feature allows the driver to launch the vehicle without a rollback while moving the foot from the brake pedal to the accelerator pedal. The electronic brake control module calculates the brake pressure that is needed to hold the vehicle on an incline and locks that pressure for a certain time by commanding the appropriate solenoid valves on and off when the brake pedal is released. Hill start assist is activated when the electronic brake control module determines that the driver wishes to move the vehicle uphill, either backwards or forwards.

The following inputs are used for the hill start assist feature:

- Brake switch
- Brake pressure sensors
- Longitudinal acceleration sensor
- Engine torque
- Reverse gear information
- Clutch switch
- Accelerator pedal position
- Vehicle speed

TPMS **Tire-pressure monitoring systems (TPMS)** are required on all new vehicles. The type often used before the 2008 model year was an *indirect* system that used the wheel speed sensors. Some vehicles such as 2010 and newer VW/Audi and many 2013 and newer Hondas use digital (active) wheel speed senor information to detect an individual low tire and is therefore able to meet the standards for tire-pressure monitoring systems.

A tire that is underinflated will have a slightly smaller rolling radius than one that is properly inflated. This will create a difference in the wheel speed sensor reading if the difference in inflation pressure is 12 PSI or more. The ABS controller will then turn on the *low tire pressure* warning lamp to warn the driver that tires need attention. To help compensate for speed variation during cornering, an indirect tire-pressure monitoring system checks the rotating speeds of diagonally opposed wheels.

- The system adds the speeds of the right front and left rear and then subtracts that value from the sum of the left front and right rear tires.
- If the total is less than or equal to a threshold value, no warning is given. However, if the total is greater than a predetermined value, the TPMS warning light is illuminated.

The warning lamp will stay on until air is added to the tire and the ignition is cycled off and on.

CASE STUDY

Weird Chevrolet Truck Brakes

The owner of a newer Chevrolet pickup truck complained that sometimes after stopping on a hill, the brakes felt as if the brakes were slow to release when the driver removed their foot from the brake pedal and started to accelerate when the traffic light turned green. The technician was able to duplicate the concern if stopped on a hill either upward or downward. The technician discovered when searching service information that the vehicle was equipped with a hill assist program. This part of the antilock brake system holds the brake applied if the longitudinal acceleration sensor senses that the vehicle was on a hill and the driver exerted a force to the brake pedal to keep the vehicle stopped. Under these conditions, the ABS controller maintained brake fluid pressure in the system to keep the brakes applied until the driver released the brake pedal. What the driver was feeling was the slight delay in the releasing of the brakes when the brake pedal was released.

Summary:

Complaint—Brakes are slow to release at times.
Cause—Normal condition when the vehicle is stopped on a hill when equipped with hill assist.
Correction—Informed driver that this is normal operation due to hill assist function.

AUTOMATIC EMERGENCY BRAKING

OPERATION **Automatic emergency braking (AEB)** is often part of a safety package that includes radar cruise control and will apply the brakes in the event of a possible collision. Sensors such as radar, sonar, and/or cameras are used depending on the system to detect the distance to another object. The controller, usually an ABS controller, then issues a warning if a collision is possible. This warning can include one or more of the following:

1. A buzzer
2. A warning light flashing on the dash
3. A vibration of the driver's seat

If the warnings are ignored, the automatic braking system will intervene and either provide brake assist or apply the brakes autonomously (by itself) to achieve maximum braking in an effort to avoid a collision. ● **SEE FIGURE 105–20**.

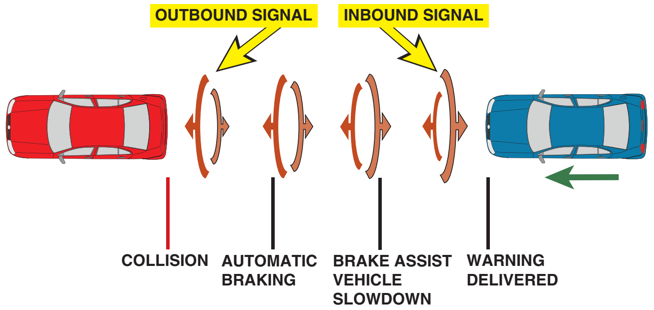


FIGURE 105–20 Sensors are used to detect when the distance is closing fast enough that a collision may be possible and the system intervenes and automatically applies the brakes if needed.

ABS DIAGNOSIS AND SERVICE

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Explain the ABS diagnostic procedure.
- Explain how to diagnose the OBD-II ABS system.
- Explain how to diagnose wheel speed sensors.
- List the steps in the hydraulic ABS service procedure.

KEY TERMS:

Amber ABS warning lamp 1274 • Red brake warning lamp (RBWL) 1274

ABS FAULT DIAGNOSIS

ABS DIAGNOSTIC STEPS Customer concerns about a fault with the antilock brake system can be best handled by performing the following:

STEP 1 **Verify the customer concern.** This step is very important because often a problem with the base brakes is thought by the customer to be a fault with the antilock brake system. It is helpful for the owner to drive the vehicle with a service technician if the problem is not readily apparent.

STEP 2 **Perform a visual inspection.** If the red brake warning lamp is on, then look for a fault such as leaks in the base brake hydraulic system, including

- Master cylinder
- Electrohydraulic control unit
- Flexible brake hoses
- Brake lines and fittings
- Calipers and/or wheel cylinders

STEP 3 **Check for stored diagnostic trouble codes (DTCs).** Use a scan tool or other necessary methods to retrieve diagnostic trouble codes. If found, follow the specified factory procedures to isolate and determine the cause.

STEP 4 **Check for technical service bulletins (TSBs).** TSBs are often helpful when trying to find the cause of a problem that cannot be easily found. Many TSBs include what DTCs are stored, so this step needs to be performed alter the diagnostic trouble codes have been retrieved.

STEP 5 **Determine the root cause.** Using all of the resources and tests as specified in service information, determine the root cause of the problem.

STEP 6 **Complete the repair.** This step may involve replacing wheel speed sensor or a hydraulic component. If a hydraulic part was replaced, then the system should be bled using the factory-specified procedure.

STEP 7 **Verify the repair.** Always test-drive the vehicle under the same conditions that were needed to verify the problem to be sure that the cause has been corrected. Clear all diagnostic trouble codes.

BRAKE WARNING LAMP OPERATION The first step in the visual diagnosis of an antilock brake system problem is to check the status of the red and/or amber brake warning lamps. ● **SEE FIGURE 106–1**.

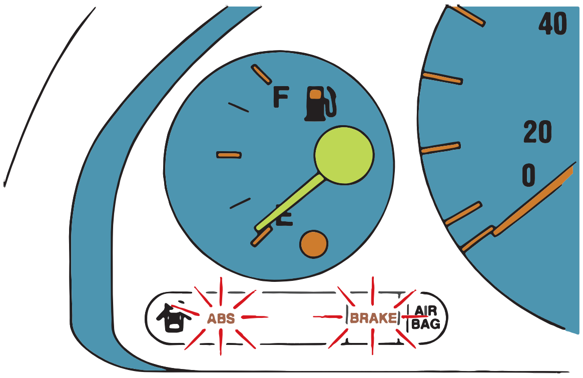

FIGURE 106–1 On most vehicles equipped with ABS, the ABS and the BRAKE warning lamp should come on as a bulb check when the ignition is first switched on.

RED BRAKE WARNING LAMP A **red brake warning lamp (RBWL)** warns of a possible dangerous failure in the base brakes, such as:

- Low brake fluid level
- Low pressure in half of the hydraulic system
- The parking brake is applied
- May light due to an ABS failure, such as low brake pressure on an integral system

AMBER ABS WARNING LAMP The **amber ABS warning lamp** usually comes on after a vehicle start during the initialization or start-up self-test sequence. The exact time the amber lamp remains on after the ignition is turned on varies with the vehicle and the ABS design. If the amber warning lamp stays on after the vehicle is started, this means that a fault in the ABS system has been detected. ● **SEE FIGURE 106–2**.

THOROUGH VISUAL INSPECTION

Many ABS-related problems can be diagnosed quickly if all the basics are carefully inspected.

A thorough visual inspection should include the following items in ● **CHART 106–1**.

TEST-DRIVE AND VERIFY THE FAULT

A test-drive is a very important diagnostic procedure. Many ABS and diagnostic trouble codes will not set unless the vehicle is moving. Often, the driver has noticed something like the self-test while driving and believed it to be a fault in the system.

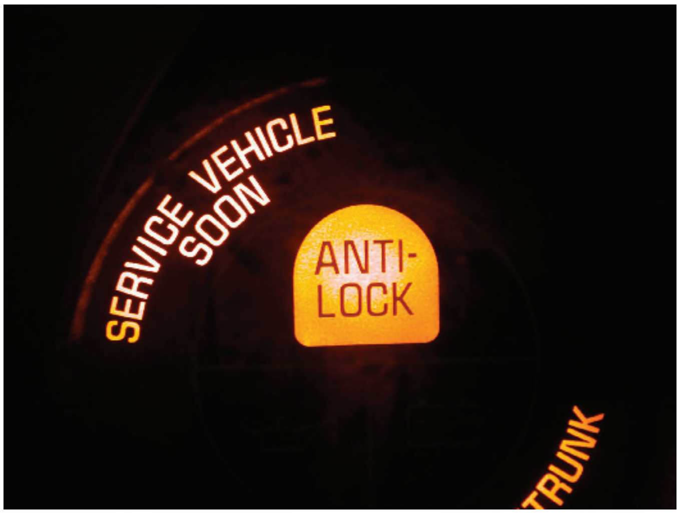

FIGURE 106–2 An amber ABS.

NOTE: Some ABS units will cause the brake pedal to move up and down slightly during cycling of the valves during the self-test. Each system has unique features. The service technician will have to learn to avoid attempting to repair a problem that is not a fault of the system.

ITEM TO CHECK	WHAT TO LOOK FOR
Brake fluid level	Check the condition and level in the reservoir.
Brake fluid leaks	Check for rusty and leaking brake lines and cracks in flexible lines or other physical damage.
Fuses and fusible links	Check all ABS-related fuses and electrical power distribution.
Wiring and connections	Check all wiring, especially wheel speed sensor leads, for damage.
Wheel speed sensors	Check that the sensor ring teeth are not damaged. Clean debris from the sensor if possible. ● **SEE FIGURE 106–3.**
NOTE: Most wheel speed sensors are magnetic and therefore can attract and hold metallic particles. Be sure to remove any metallic debris from around the magnetic wheel speed sensor.	
Parking brake	Check that the parking brake is correctly adjusted and fully released.
Wheel bearings	All wheel bearings must be free of defects and adjusted properly.
Wheels and tires	Check for correct size, proper inflation, and legal tread depth.

CHART 106–1

Items that should be checked when diagnosing a concern about the antilock brake system (ABS).

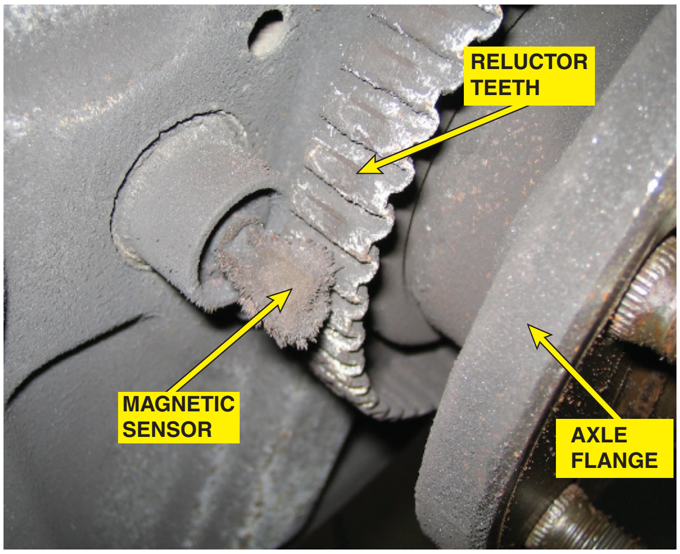

FIGURE 106–3 A visual inspection of the wheel speed sensor on this older vehicle showed metal "fuzz" had been attracted to the magnetic sensor.

TECH TIP

Check for Flood Damage

There are often strange electrical problems that can occur including false DTCs or intermittent operation of electrical sensors, ABS, accessories, or gauges. Sometimes the root of these problems is due to rust and corrosion after a vehicle is involved in a flood.

Here are some telltale signs that a vehicle may have due to flooding:

- Mud, silt, or caked dust under the dash and inside the doors
- Corroded electrical connectors at the computer, fuse box, or ABS controller (computer)
- Visible waterline in the doors or behind panels
- Rust in abnormal places such as seat springs or brackets behind the dash
- Moisture in lenses
- Musty smell and/or strong air freshener smell
- Powdery corrosion on aluminum parts such as intake manifold and inside the throttle bore
- Rust or moisture inside electrical switches or relays
- Areas that are normally dusty, such as an ashtray or glove box, are very clean

FREQUENTLY ASKED QUESTION

What's That Noise and Vibration?

Many vehicle owners and service technicians have been disturbed to hear and feel an occasional groaning noise. It is usually heard and felt through the vehicle after first being started and driven. Because it occurs when first being driven in forward or reverse, many technicians have blamed the transmission or related driveline components. This is commonly heard on many ABS vehicles as part of a system check. As soon as the ABS controller senses speed from the wheel speed sensors after an ignition cycles on, the controller will run the pump either every time or whenever the accumulator pressure is below a certain level. This can occur while the vehicle is being backed out of a driveway or being driven forward because wheel sensors can only detect speed—not direction. Before serious and major repairs are attempted to "cure" a noise, make sure that it is not the normal ABS self-test activation sequence of events.

Before driving, start the engine and observe the red and/or amber brake warning lamps.

- If the red brake warning lamp is on, the base brakes may not be functioning correctly. Do not drive the vehicle until the base brakes are restored to proper operation.
- If the amber warning lamp is on, then the vehicle can be carefully driven because the antilock brake system will not likely be functioning when the warning lamp is on.

ABS DIAGNOSIS

SCAN TOOL DIAGNOSIS Most vehicles built since 1996 use the OBD-II diagnostic connector to transmit ABS diagnostic trouble code information to a scan tool. A factory scan tool or an enhanced factory-level scan tool will be needed to retrieve ABS diagnostic trouble codes (DTCs) and scan tool data such as wheel speed sensor information. Scan tools can be divided into three basic groups:

1. **Factory scan tools.** These are the scan tools required by all dealers that sell and service the brand of vehicle. Examples of factory scan tools include
   - **General Motors**—Tech 2 or GM MDI and GDS II (Global Diagnostic System II). ● **SEE FIGURE 106–4**.
   - **Ford**—New Generation Star (NGS) and IDS (Integrated Diagnostic Software), VCM, VCM2, or VCM3
   - **Chrysler**—DRB-III or Star Scan, wiTECH
   - **Honda**—HDS or Master Tech
   - **Toyota**—Master Tech or Techstream ADVi

   All factory scan tools are designed to provide bidirectional capability, which allows the service technician the opportunity to operate components using the scan tool, thereby confirming that the component is able to work when commanded. Also, all factory scan tools are capable of displaying all factory parameters.
2. **Aftermarket scan tools.** These scan tools are designed to function on more than one brand of vehicle. Examples of aftermarket scan tools include
   - **Snap-on**—Various models available including the Solus, Ethos, Verus, and Modis
   - **OTC**—Various models available including Encore, Pegasus, Genisys, and Task Master
   - **Launch**—Various models available
   - **Autel**—Various models available
   - **AutoEnginuity** and other programs that use a laptop or handheld computer for the display

   While many aftermarket scan tools can display most if not all of the parameters of the factory scan tool, there can be a difference when trying to troubleshoot some faults.

3. **Code readers.** Many lower cost scan tools offer limited diagnostic information and many will not be able to retrieve or display ABS-related diagnostic trouble codes. Many global (generic) scan tools are only capable of reading emission-related DTCs. If purchasing a low-cost code reader, select one that has the ability to read ABS-related codes. However, these tools are often *not* able to display data such as vehicle speed from each wheel speed sensor.

OBD-II CONNECTOR The data link connector (DLC) is a standardized 16 cavity connector where a scan tool can be connected to retrieve diagnostic information from the vehicle's computers. The normal location is under the dash on the driver's side usually located within 12 inches (30 cm) of the center of the vehicle. It can be covered but if it is, then the cover has to be able to be removed without the use of a tool, such as when it is located underneath the ash tray.

CASE STUDY

The Mystery ABS Amber Warning Light

The owner complained to a service technician that the ABS warning light would come on but only while driving down from a parking garage. When the driver turned off the ignition and restarted the engine, the ABS amber light was not on and did not come on again until the vehicle was again driven down the spiral parking garage ramp. The service technician used a scan tool and found that no DTCs had been stored.

NOTE: Some ABS systems will not retain a DTC unless the problem is currently present and the ABS amber warning light is on.

All of the brakes were in excellent condition, but the brake fluid level was down a little. After topping off the master cylinder with clean DOT 3 brake fluid, the vehicle was returned to the customer with the following information:

- The ABS amber warning light may have been triggered by the brake fluid level switch. While driving down the steep parking garage ramp, the brake fluid moved away from the fluid level sensor.

NOTE: While the brake fluid level sensor normally would turn on the red brake warning light, in some systems it turns on the amber ABS light if the brake fluid falls below a certain level in the ABS reservoir.

- The difference in wheel speed between the outboard and the inboard wheels could have triggered a fault code for a wheel speed sensor during the drive down the spiral parking garage ramp.

Summary:

Complaint—Driver stated that the amber ABS warning lamp would come on but only when descending in a parking garage.
Cause—Possible low brake fluid level or normal operation due to change in wheel speed while turning sharply.
Correction—Added a slight amount of brake fluid to return the level to the "MAX" level and returned to owner.

CASE STUDY

The Nervous Honda Civic

A customer complained that sometimes during normal braking, the ABS would be activated (brake pedal pulsated) just before coming to a stop. However, the ABS light would not come on. The service technician was able to duplicate the condition and there were no DTCs stored. Using a scan tool to monitor the wheel speed sensors, the technician discovered that the left front wheel speed was slightly different than the others. A thorough visual inspection revealed that the tone wheel (reluctor ring) was cracked. This crack created a different wheel speed signal to the ABS controller than the other wheels and the controller activated the ABS as it would normally—that was why there were no DTCs. Other things that could have caused this problem, which is often called "false modulation," include a bent wheel, mismatched tire sizes, or metal debris around the sensor.

Summary:

Complaint—Driver complained that the ABS caused the brake pedal to pulsated but only when the vehicle was slowing to a stop.
Cause—A cracked tone (reluctor) ring was discovered on the right front.
Correction—The customer authorized the replacement of a new wheel bearing assembly which included the tone ring and the problem was corrected.

"C" (CHASSIS) DTCS The antilock brake system (ABS) may trigger different faults to indicate ABS performance concerns. They may be related to performance concerns in the system, components, internal control performance, programming, and communication.

The ABS control module, commonly called the electronic brake control module (EBCM), is used to control ABS operation. The EBCM/BCM uses the signals provided by the wheel speed sensors to monitor the rotational speed of each wheel. A wheel that is about to lock up or slip will begin to rotate much slower than the other wheels when the brake pedal is applied. If the EBCM detects an impending wheel lockup, it will operate the appropriate valves in the brake pressure modulator valve along with the hydraulic pump in order to keep the wheel rotating while still maintaining a high level of deceleration.

The EBCM is capable of recognizing a fault with the ABS. The EBCM constantly monitors ABS inputs and outputs for erroneous signals that could indicate a component is not operating properly or that a circuit or component is damaged. If the EBCM recognizes a fault, it records a diagnostic trouble code, illuminates the ABS warning lamp in the instrument panel cluster, and may also disable certain ABS functions. ● **SEE CHART 106–2** for a list of global (generic) ABS-related "C" codes.

TECH TIP

Space Saver Spare Tire May Trigger Wheel Speed Fault Code

If a vehicle has been using a small space saver-type spare tire, then the difference in outside diameter may trigger a wheel speed sensor diagnostic trouble code (DTC) and turn on the amber ABS warning lamp. Try to find out from the customer if they had driven on a spare tire before replacing a wheel speed sensor based on a stored DTC.

TECH TIP

Check Power and Ground First

Before replacing an expensive EBCM, make sure to verify power and ground circuits at the EBCM connector. Also check power and ground at the other end of the harness, such as at the fuse box and fuses and the bolted ground connection on the vehicle chassis. ● **SEE FIGURE 106–5**.

CONTROL MODULE INTERNAL PERFORMANCE FAULT A control module internal performance fault indicates that there is a malfunction internal to the EBCM that cannot be repaired at the dealership. Typically, if an EBCM reports an internal performance fault, the EBCM must be replaced.

COMMUNICATION FAULT If the EBCM is unable to communicate with another module on its network, the EBCM may set a communication fault. This type of fault likely does not indicate that there is a problem within the ABS, but rather sets as a result of another module failing to communicate with the EBCM.

COMPONENT-RELATED FAULT A component-related fault specifically identifies an ABS component that is not functioning properly. While an ABS component–related fault will name an ABS component in its description, do not assume that the component has failed. This fault sets to indicate that a fault has affected the operation of the component named in the description. Further diagnosis is required to identify the cause of the fault.

FIGURE 106–5 (a) This corroded electrical connector to the ABS hydraulic control module helped explain why there were many stored diagnostic trouble codes (DTCs). (b) The male terminals also showed signs of corrosion inside this connector.

WHEEL SPEED SENSOR DIAGNOSIS

COMMON CAUSES OF FAULTS Wheel speed sensor (WSS) circuits are often the cause of many ABS problems. These components may suffer from physical damage, buildup of metallic debris on the sensor tip, corrosion, poor electrical connections, and damaged wiring.

PASSIVE WHEEL SPEED SENSOR DIAGNOSIS The passive wheel speed sensor generates an alternating current (AC) voltage as the teeth of a tone wheel pass by. The sensor contains a permanent magnet and a coil of wire. The reluctor notches disturb the magnetic field, causing the sensor to output a small AC voltage signal. After performing a good visual check of the wiring and connectors, use a DVOM and/or oscilloscope to check the wheel speed sensors. ● **SEE FIGURE 106–6.**

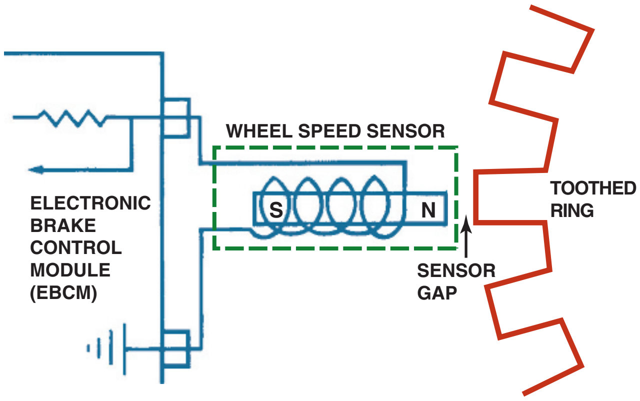

FIGURE 106–6 Typical wheel speed sensor. When a tooth on the sensor ring is close to the sensor, the strength of the magnetic field is stronger because the metal of the tooth conducts magnetic lines of force better than air. When the tooth moves away, the magnetic field strength is reduced. It is this changing magnetic field strength that produces the changing voltage. Frequency of the signal is determined by the speed of the rotating sensor.

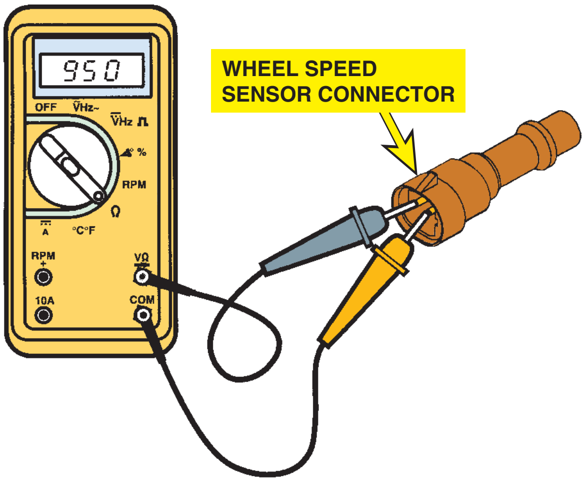

FIGURE 106–7 Measuring the resistance of a wheel speed sensor.

RESISTANCE MEASUREMENT The resistance of most WSS ranges from 800 to 2,500 ohms (Ω). Therefore, a reading of about 1,000 ohms (1 kΩ) would indicate proper sensor coil resistance.

Always check service information for the specified resistance for the wheel speed sensor on the vehicle being tested. ● **SEE FIGURE 106–7.**

CHECKING FOR SHORT-TO-GROUND To check for a short-to-ground, connect either lead of the ohmmeter to one of the WSS wires and the other to a good, clean chassis ground. The resistance should be infinity (OL). If a low resistance reading is obtained, the sensor or sensor wiring is shorted-to-ground and must be replaced.

AC VOLTAGE CHECK To check for the proper AC voltage output from a wheel speed sensor, connect a digital meter to the WSS terminals or input to the controller in the breakout box and set the meter to read AC volts. Rotate the wheel by hand at a rate of one revolution per second. A good WSS should produce voltage of at least 0.1 volt (100 mV). A sensor voltage of lower than 0.1 volt (100 mV) may be caused by three things.

1. Excessive clearance between the sensor and the tone ring
2. Buildup of debris on the end of the sensor. Most wheel speed sensors are magnetic and can attract metallic particles, which can affect the operation of the sensor.

TECH TIP

Perform a "Wiggle Test"

Whenever testing a wheel speed sensor, it is a good idea to move or wiggle the sensor wiring and connector when taking a resistance or voltage measurement in case of a broken wire or corroded connector. If the reading on the meter changes when the wiring is being moved, then this confirms that there is a possible problem with the wiring or the connections so further diagnosis will be needed.

3. Excessive resistance in the sensor or sensor wiring, which can also cause a weak signal to be produced by the WSS.

SCOPE TESTING To test a wheel speed sensor using a scope, attach the scope leads to the sensor terminals or to the input connector on the breakout box. Rotate the wheel by hand or by using engine power with the vehicle safely hoisted with all four wheels off the ground.

- A good WSS should produce an alternating current sine wave signal that increases in frequency and amplitude with increasing wheel speed. ● **SEE FIGURE 106–8**.
- Damaged or missing teeth on the tone ring will cause flat spots or gaps in the sine wave pattern. ● **SEE FIGURE 106–9**.

A bent axle or hub will produce a wavelike pattern that fluctuates as the strength of the sensor signal changes with each revolution.

SCAN TOOL TESTING A scan tool can be used to check for the proper operation of the WSS. As an assistant drives the vehicle, connect the scan tool and monitor the speed of all of the sensors. All of the sensors should indicate the same speed. If a sensor shows a slower or faster speed than the others, carefully check the tone ring for damage such as a crack.

TECH TIP

Quick and Easy Wheel Speed Sensor Diagnosis

A fault in a wheel speed sensor (WSS) is a common ABS problem. A quick and easy test that works on most Bosch ABS (and perhaps others) involves the following steps:

STEP 1 Hoist the vehicle safely.

STEP 2 Key on, engine off (KOEO).

STEP 3 Spin a tire by hand as fast as possible.

STEP 4 The ABS amber warning light should come on, indicating that a speed was detected but not by all the wheel speed sensors.

STEP 5 Turn the ignition off to reset the ABS warning light.

STEP 6 Repeat the test on each of the remaining wheels.

If any wheel fails to turn on the ABS light, carefully inspect the wheel speed sensor for proper resistance and the tone ring and wiring. If the ABS light is on all the time and does not reset when the ignition is turned off, the problem is not caused by a wheel speed sensor.

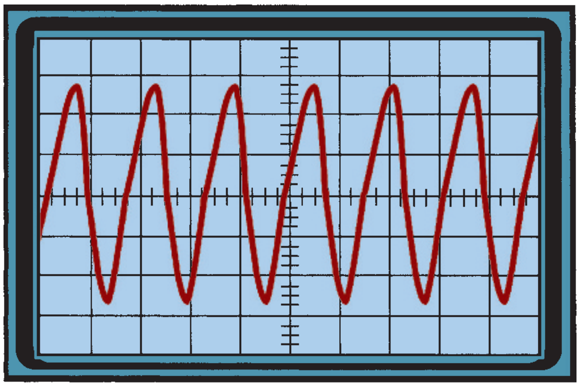

FIGURE 106–8 A scope can be used to check for proper operation of a wheel speed sensor.

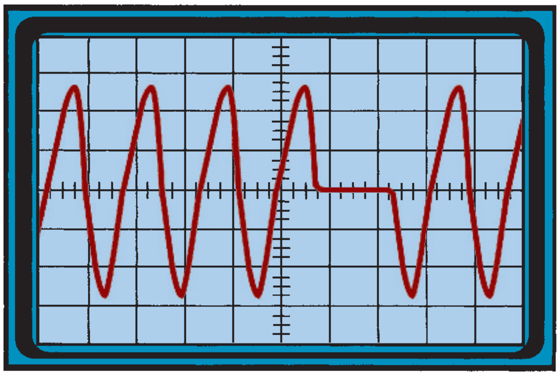

FIGURE 106–9 A broken tooth on a wheel speed sensor tone ring shows on the scope trace as a missing wave.

FREQUENTLY ASKED QUESTION

Why Does My Scan Tool Show Speed When Stopped?

Some vehicles, especially older General Motors vehicles (Chevrolet, Buick, Pontiac, Cadillac, and GMC), will show 2 or 3 MPH on the scan tool with the vehicle in the shop and not moving. This is perfectly normal and there is no fault so no service or repair is needed to be performed. The reading seems to be a default reading because many passive wheel speed sensors are not capable of supplying a usable wheel speed until over 3 MPH.

ACTIVE WHEEL SPEED SENSOR DIAGNOSIS Many 2005 and newer vehicles use active wheel speed sensors. To test an active (digital) wheel speed sensor, perform the following steps:

STEP 1 These sensors are most easily checked using a scan tool. With the scan tool attached, drive the vehicle straight while an assistant observes the speed of each wheel. All four wheel speed sensors should read the same speed when driving straight ahead.

STEP 2 Check that battery voltage is available at the sensor with the key on, engine off (KOEO). If the sensor does not have 12 volts, then the problem is most likely in the ABS controller or the wiring between the controller and the sensor.

FREQUENTLY ASKED QUESTION

Is a Wheel Speed Sensor Adjustable?

Some older ABS applications use adjustable wheel speed sensors. Most sensors adjust by first loosening a set screw, then inserting a nonmagnetic brass or plastic feeler gauge between the tip of the sensor and a high point on the tone ring.

When installing a new wheel speed sensor, look for a piece of paper or plastic on the tip. The paper or plastic is the precise thickness to guarantee a correct air gap between the tip of the sensor and the tone ring. Adjust the sensor so the tip just touches the tone ring and you can slip the paper or plastic out without ripping it. Tighten the setscrew and the air gap is properly set. ● **SEE FIGURE 106–10**.

STEP 3 Check the low reference (signal ground) circuit. With the ignition off and the wheel speed sensor disconnected, measure the resistance between the wheel speed sensor's low reference circuit and ground. The resistance should be no greater than 5 ohms.

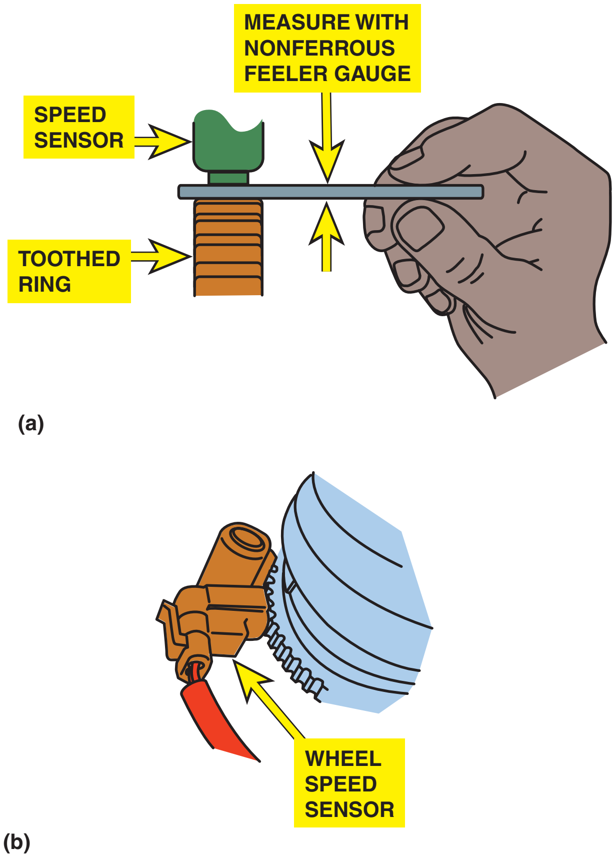

FIGURE 106–10 (a) Always use a nonferrous (brass or plastic) feeler (thickness) gauge when measuring the gap between the toothed ring and the wheel speed sensor. (b) Sometimes a sensor is equipped with a paper spacer that is the exact thickness of the spacing required between the toothed ring and the sensor. If equipped, the sensor is simply installed with the paper touching the toothed wheel. A typical gap ranges from 0.020 to 0.050 inch (0.5 to 1.3 mm).

STEP 4 Measure the signal voltage provided by the EBCM along the wheel speed sensor signal circuit KOEO. The voltage should be greater than 11 volts.

HYDRAULIC ABS SERVICE

CHECK SERVICE INFORMATION Before doing any brake work on a vehicle equipped with antilock brakes, always check the service information for the exact vehicle being serviced. For example, some manufacturers recommend discharging the hydraulic accumulator by depressing the brake pedal many times before opening bleeder valves. Many service checks require that a pressure gauge be installed in the system.

BLEEDING THE ELECTRONIC-HYDRAULIC ASSEMBLY Air can easily get trapped in the ABS electronic-hydraulic (E-H) assembly whenever the hydraulic system is opened. Even though the master cylinder and all four wheel cylinders/calipers have been bled, sometimes the brake pedal will still feel spongy. Some E-H units can be bled through the use of a scan tool where the valves are pulsed in sequence by the electronic brake controller (computer). Some units are equipped with bleeder valves while others must be bled by loosening the brake lines. Bleeding the E-H unit also purges out the older brake fluid, which can cause rust and corrosion damage. Always check the label on the brake fluid reservoir and/or service information or owner's manual for the specified brake fluid to use.

CAUTION: When checking brake fluid level, some integral ABS and hybrid brake systems using an accumulator unit requires that the brake pedal be depressed as many as 40 times to discharge brake fluid fully from the accumulator. Failure to discharge the accumulator fully can falsely show that the brake fluid level is too low. If additional brake fluid is added, the fluid could overflow the reservoir during an ABS stop when the accumulator discharges brake fluid back into the reservoir.

MANUALLY BLEEDING ABS WHEEL BRAKES During routine brake service, attempt to keep the air from entering the hydraulic system by doing the following:

1. Do not allow the brake system to run dry. Use a brake pedal depressor or plug any open brake line to keep brake fluid from flowing out of the brake master cylinder reservoir.
2. Do not allow the master cylinder to run dry during the bleeding operation. Check the master cylinder reservoir often and keep it filled with fresh brake fluid from a sealed container.
3. Always bench bleed a replacement master cylinder to help prevent against introducing air into the hydraulic system. After depressing the unit as per manufacturer's recommended procedures, the brakes can be bled using the same procedure as for a vehicle without ABS. Air trapped in the ABS hydraulic unit may require that a scan tool be used to cycle the valves. ● **SEE FIGURES 106–11 AND 106–12**.

The bleeding procedure for vehicles equipped with antilock brakes is often different than vehicles without ABS. Check service information for the specified bleeding procedure and sequence.

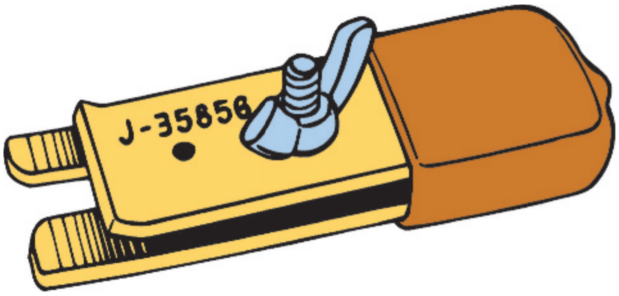

FIGURE 106–11 Special bleed valve tools are often required when bleeding some ABS units such as the Kelsey-Hayes 4WAL system.

SCAN TOOL BLEEDING To bleed the system using a scan tool, use the following steps:

STEP 1 Check service information and determine the specified procedure to follow. This usually involves manually bleeding the wheel brakes before using a scan tool.

STEP 2 Use a factory scan tool or one that is capable of performing an automated bleed procedure.

STEP 3 Connect the scan tool to the data link connector (DLC).

STEP 4 Enter vehicle information as shown on the display of the scan tool and locate the antilock brake system function area.

STEP 5 Select ABS-automated bleed from the ABS menu. The instructions on the scan tool could include several steps including manually bleeding the system, then allowing the scan tool to cycle the hydraulic ABS solenoid valves and then bleeding again.

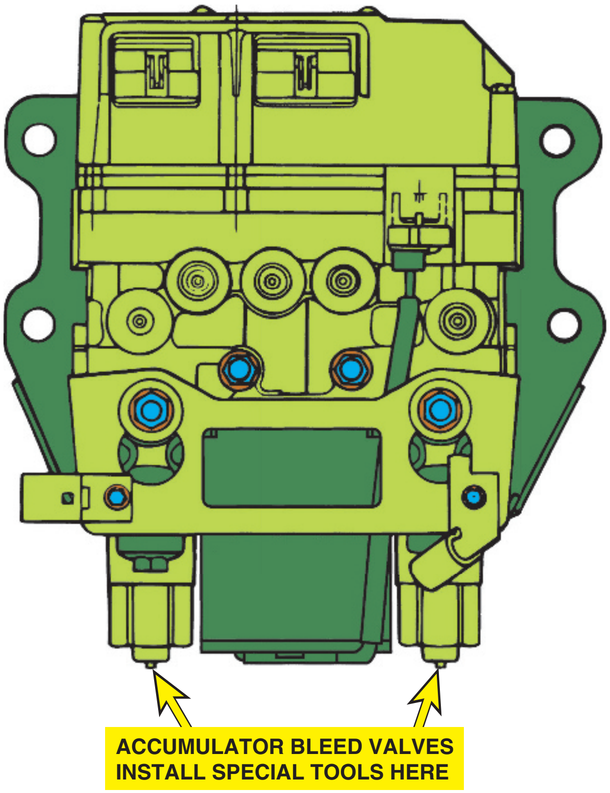

FIGURE 106–12 Two bleed valve tools are needed to bleed the Kelsey-Hayes 4WAL system, which attaches to the bleeder valves on the accumulator.

REVIEW QUESTIONS

1. Why should the operation of the red and amber brake warning lamps be included in the diagnostic procedure?

ELECTRONIC STABILITY CONTROL SYSTEMS

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Discuss the need for electronic stability control (ESC).
- Describe the FMVSS requirements.
- Describe the sine with dwell (SWD) test.
- List the sensors needed for the ESC system.
- Describe how a traction control (TC) system works.
- Explain how to diagnose ESC/TC system faults.

KEY TERMS:

Electronic brake control module (EBCM) 1285 • Electronic stability control (ESC) 1283 • Hand-wheel position sensor 1285 • Lateral acceleration sensor 1285 • Oversteering 1283 • Positive slip 1287 • Sine with dwell (SWD) test 1284 • Steering wheel position sensor 1285 • Telltale light 1284 • Traction control (TC) 1287 • Understeering 1283 • Vehicle speed (VS) sensor 1285 • Yaw rate sensor 1286

THE NEED FOR ELECTRONIC STABILITY CONTROL

PURPOSE AND FUNCTION **Electronic stability control (ESC)** is a system designed to help drivers to maintain control of their vehicles in situations where the vehicle is beginning to lose control. Keeping the vehicle on the road prevents run-off-road crashes, which are the conditions that lead to most single-vehicle accidents and rollovers.

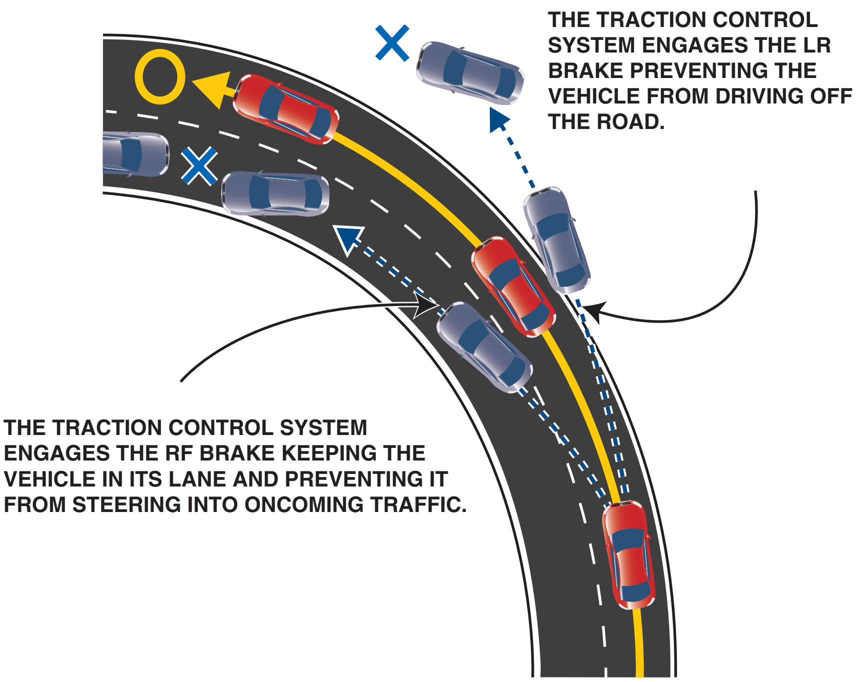
SYSTEM REQUIREMENTS The ESC is defined as a system that has all of the following features:

1. Helps vehicle directional stability by applying and adjusting individual wheel brakes to help bring the vehicle back to the intended direction.
2. Uses sensors to determine when the vehicle is not under control.
3. Uses a steering wheel position sensor to determine the intended direction of the driver.
4. Operates at all vehicle speeds, except at low speeds where loss of control is unlikely.

The electronic stability control system applies individual wheel brakes to bring the vehicle under control if either of the following conditions occur:

- **Oversteering**—In this condition, the rear of the vehicle tends to move outward or breaks loose, resulting in the vehicle spinning out of control. This condition is also called *loose*. If the condition is detected during a left turn, the ESC system would apply the right front brake to bring the vehicle back under control.
- **Understeering**—In this condition, the front of the vehicle tends to continue straight ahead when turning, a condition that is also called *plowing* or *tight*. If this condition is detected during a right turn, the ESC system would apply the right rear wheel brake to bring the vehicle back under control. ● **SEE FIGURE 107–1**.

NOTE: When the brakes are applied during these corrections, a thumping sound and vibration may be sensed.



THE TRACTION CONTROL SYSTEM ENGAGES THE LR BRAKE PREVENTING THE VEHICLE FROM DRIVING OFF THE ROAD.
THE TRACTION CONTROL SYSTEM ENGAGES THE RF BRAKE KEEPING THE VEHICLE IN ITS LANE AND PREVENTING IT FROM STEERING INTO ONCOMING TRAFFIC.

FIGURE 107–1 The electronic stability control (ESC) system applies individual wheel brakes to keep the vehicle under control of the driver.

TELLTALE LAMP The ESC lamp, called a **telltale light**, is required to remain on for as long as the malfunction exists, whenever the ignition is in "On" ("Run") position. The ESC malfunction telltale will flash to indicate when the ESC system is operating to help restore vehicle stability.

ESC SWITCH Some, but not all, vehicle manufacturers install a switch to temporarily disable or limit the ESC functions. This allows the driver to disengage ESC or limit the operation when the full ESC might not be needed such as:

- When a vehicle is stuck in sand/gravel
- When the vehicle is being operated on a racetrack for maximum performance

The electronic stability control system is turned back on when the ignition is turned off and then back on and is in the default position.

FEDERAL MOTOR VEHICLE SAFETY STANDARD (FMVSS) NO. 126

Federal Motor Vehicle Safety Standard (FMVSS) No. 126 (June 26, 2008), Electronic Stability Control Systems, requires that all passenger cars, multipurpose passenger vehicles, trucks, and buses that have a gross vehicle weight rating (GVWR) of 10,000 pounds (4,536 kg) or less to be equipped with an electronic stability control system by September 1, 2011 (2012 model-year vehicles).

The ESC system must meet the following requirements:

1. The ESC system must be able to apply all four brakes individually. This means that the vehicle must be equipped with a four-channel antilock brake system (ABS) which uses a wheel speed sensor at each wheel.
2. The ESC must be programmed to work during all phases of driving including acceleration, coasting, and deceleration (including braking).
3. The ESC system must work when the antilock brake system or traction control is activated.

SINE WITH DWELL TEST

The standardized test used to determine if an electronic stability control system functions okay is called the **sine with dwell (SWD) test**. A vehicle is driven at 50 mph (80 km/h) and driven on a curved course that looks like a sine wave or the letter "S" on its side. Then the vehicle is held in a straight-ahead position for 0.5 second (500 ms) and before being steered back onto the curved section of the test. ● **SEE FIGURE 107–2**.

FIGURE 107–2 The sine with dwell test is designed to test the electronic stability control (ESC) system to determine if the system can keep the vehicle under control.

The quick changes involved in this test are designed to upset the chassis of the vehicle and cause the electronic stability control system to act to keep the vehicle under control during the entire test.

Stability control systems are offered under the following names:

- **Acura:** Vehicle Stability Assist (VSA)
- **Audi:** Electronic Stabilization Program (ESP)

FREQUENTLY ASKED QUESTION

Can a Vehicle with a Modified Suspension Pass the Test?

Yes, if the system is properly engineered. To be sure, check with the company offering a suspension test to verify that the vehicle will still be able to pass the sine with dwell (SWD) test. This ensures that any changes are within the range where the ESC system can control the vehicle during emergency maneuvers. ● **SEE FIGURE 107–3.**

FIGURE 107–3 Using a simulator is the most cost-effective way for vehicle and aftermarket suspension manufacturers to check that the vehicle is able to perform within the FMVSS No. 126 standard for vehicle stability.

ESC SENSORS

STEERING WHEEL POSITION SENSOR Depending on the vehicle, the **steering wheel position sensor** may also be called a **hand-wheel position sensor**. The function of this sensor is to provide the driver's intended direction with signals relating to steering wheel position, speed, and direction. ● **SEE FIGURES 107–4 AND 107–5.**

VEHICLE SPEED SENSOR The **vehicle speed (VS) sensor** is used by the **electronic brake control module (EBCM)** to help control the suspension system. The vehicle speed sensor is a magnetic sensor and generates an analog signal whose frequency increases as the speed increases. ● **SEE FIGURE 107–6.**

LATERAL ACCELERATION SENSOR The function of the **lateral acceleration sensor** is to provide the suspension control

module with feedback regarding vehicle cornering forces. This type of sensor is also called a G-sensor, with the letter "G" representing the force of gravity. For example, when a vehicle enters a turn, the sensor provides information as to how hard the vehicle is cornering. This information is processed by the suspension control module to provide appropriate damping on the inboard and outboard dampers during cornering events.

This sensor can be either a stand-alone unit or combined with the yaw rate sensor.

Typically, the sensor is mounted in the passenger compartment:

- under the front seat
- in the center console
- on the package shelf

● **SEE FIGURE 107–7**.

YAW RATE SENSOR The **yaw rate sensor** provides information to the suspension control module and the EBCM. This information is used to determine how far the vehicle has deviated from the driver's intended direction. ● **SEE FIGURE 107–9**.

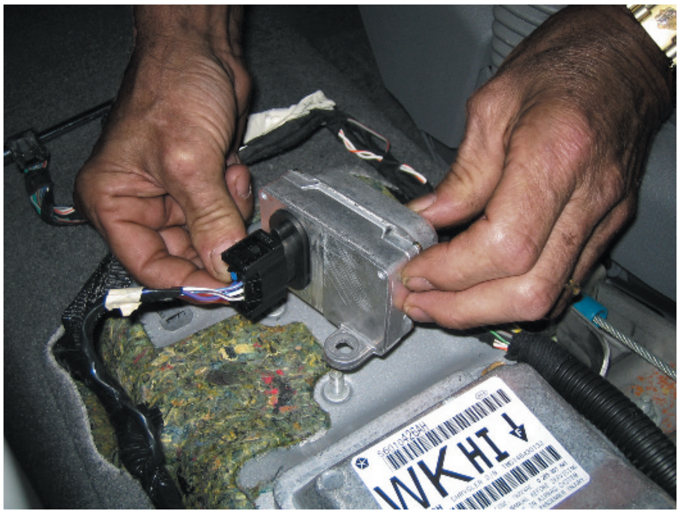

FIGURE 107–8 A lateral acceleration sensor is usually located under the center console and can be easily checked by unbolting it and turning it on its side while monitoring the sensor value using a scan tool. When it is on its side, the sensor value should read 1.0 G.

TECH TIP

Quick and Easy Lateral Acceleration Sensor Test

Most factory scan tools will display the value of sensors, including the lateral acceleration sensor. However, the sensor value will read zero unless the vehicle is cornering. A quick and easy test of the sensor is to simply unbolt the sensor and rotate it 90 degrees with the key on engine off. ● **SEE FIGURE 107–8**. Now the sensor is measuring the force of gravity and should display 1.0 G on the scan tool. If the sensor does not read close to 1.0 G or reads zero all of the time, the sensor or the wiring is defective.

This sensor can be either a stand-alone unit or combined with the lateral acceleration sensor. Typically, the sensor is mounted in the passenger compartment under the front seat, in the center console, or on the rear package shelf.

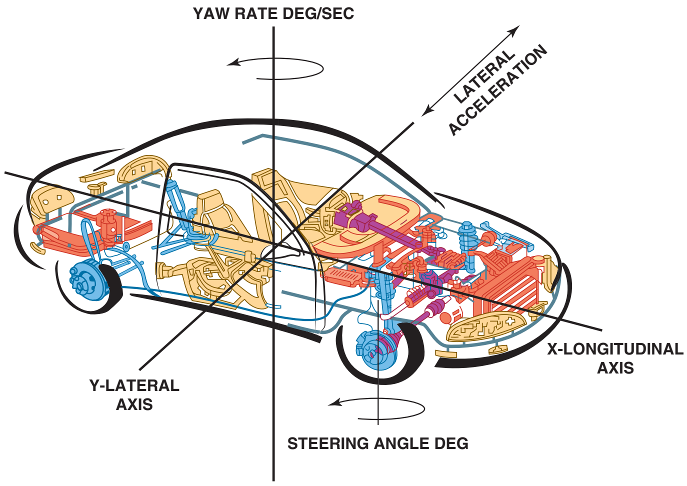

FIGURE 107–9 The yaw sensor is used to determine the rate that the vehicle is rotating around its axis, measured in degrees per second (deg/sec).

This sensor does set DTC codes. These codes can be found in service information. ● **SEE FIGURE 107–10**.

TRACTION CONTROL

PURPOSE AND FUNCTION

Traction control (TC) can be separate or used as part of the electronic stability control system. Traction control allows an ABS to control wheel spin during acceleration. When tires lose traction during acceleration, it is called **positive slip**.

Low-speed traction control uses the braking system to limit positive slip up to a vehicle speed of about 30 mph (48 km/h). Traction control is usually a part of the electronic stability control system. ● **SEE FIGURE 107–11**.

Traction control uses the same wheel speed sensors as ABS, but requires additional programming in the control module so the system monitors wheel speed continuously, not just when braking. Traction control also requires the following:

- Additional solenoids in the hydraulic modulator so the brake circuits to the drive wheels can be isolated from the non-drive wheels when braking is needed to control wheel spin.
- Use of a pump and accumulator to generate and store pressure for traction control braking. If a wheel speed sensor detects wheel spin in one of the drive wheels during acceleration, the control module energizes a solenoid that allows stored fluid pressure from the accumulator to apply the brakes on the wheel that is spinning. This slows the wheel that is spinning and redirects engine torque through the differential to the opposite drive wheel to restore traction.

Traction control works just as well on front-wheel-drive vehicles as it does on rear-wheel-drive vehicles.

SYSTEM COMPONENTS

The main controller for the traction can include one of the following, depending on make, model, and year of vehicle:

1. The body control module (BCM)
2. The powertrain control module (PCM)
3. The antilock brake system controller

The controller uses inputs from several sensors to determine if a loss of traction is occurring. The input signals used for traction control include the following:

- **Throttle position (TP) sensor**—This indicates the position of the throttle, which is the driver command for power.
- **Wheel speed sensor (WSS)**—The controller monitors all four wheel speed sensors. If one wheel is rotating faster than the other, this indicates that the tire is slipping or has lost traction.
- **Engine speed (RPM)**—This information is supplied from the engine controller powertrain control module and indicates the speed of the engine.
- **Transmission range switch**—Determines which gear the driver has selected so that the PCM can take corrective action.

TRACTION CONTROL OPERATION

The outputs of the traction control system can include one or more of the following:

- Retard ignition timing to reduce engine torque.
- Decrease the fuel injector pulse-width to reduce fuel delivery to the cylinder to reduce engine torque.

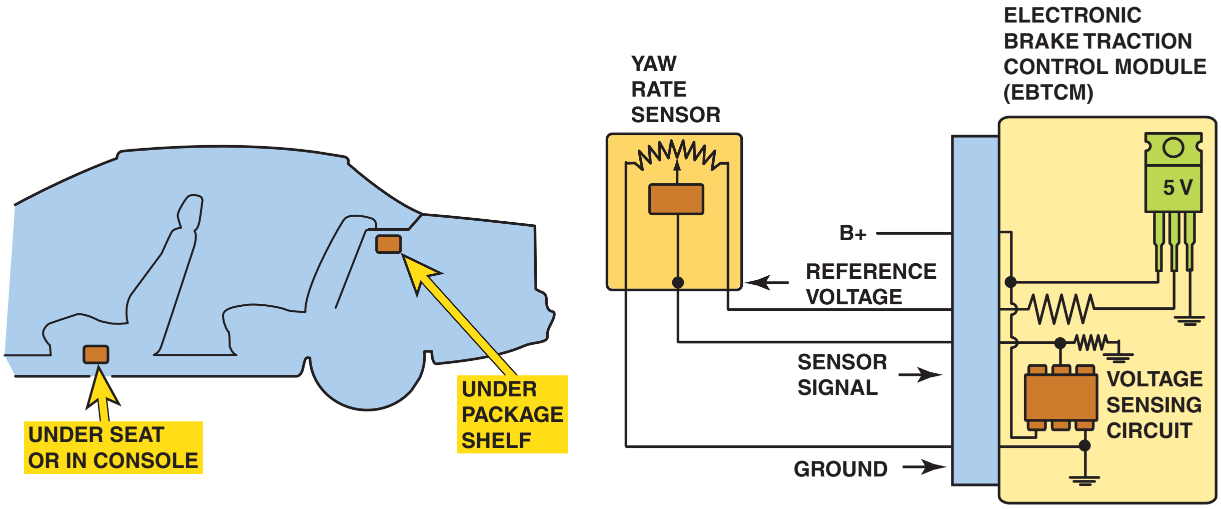

FIGURE 107–10 Yaw rate sensor showing the typical location and schematic.

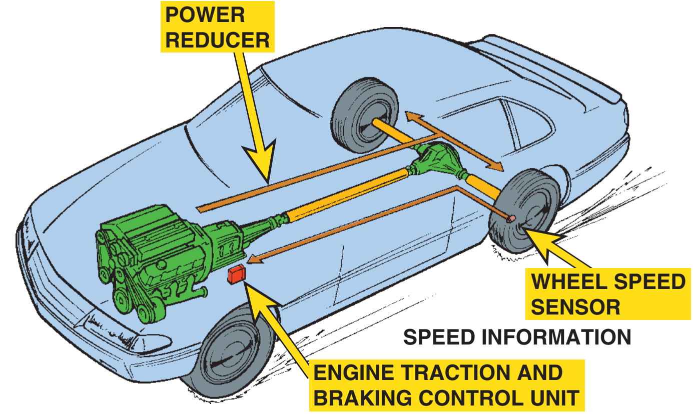

FIGURE 107–11 Typical traction control system that uses wheel speed sensor information and the engine controller (PCM) to apply the brakes at lower speeds and also reduce engine power applied to the drive wheels.

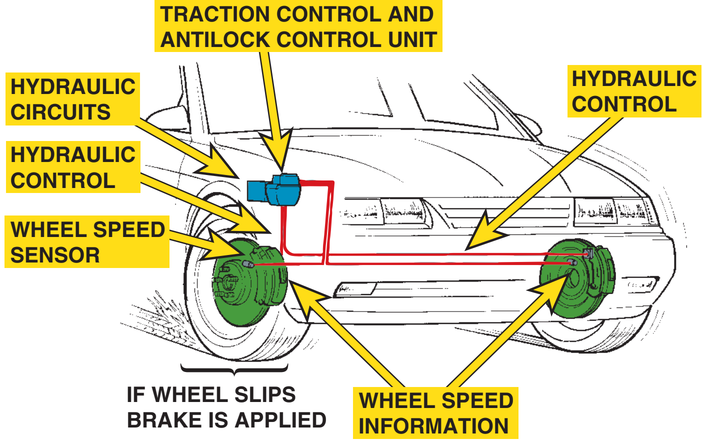

FIGURE 107–12 Wheel speed sensor information is used to monitor if a drive wheel is starting to spin.

- Reduce the amount of intake air if the engine is equipped with an electronic throttle control (ETC). Reduced airflow will reduce engine torque.
- Upshift the automatic transmission/transaxle. If the transmission is shifted into a higher gear, the torque applied to the drive wheels is reduced.

Most traction control systems are capable of reducing positive wheel slip at all vehicle speeds. Most speed traction control systems use accelerator reduction and engine power reduction to limit slip before applying the brakes to the wheel that is spinning. This action helps reduce the possibility of overheating the brakes if the vehicle were being driven on an icy or snow-covered road. ● **SEE FIGURE 107–12**.

Therefore, the controller usually performs actions to restore traction in the following order:

1. Reduces engine torque to the drive wheels. This can include some or all of the following:
   - Retard spark timing
   - Reduce injector on-time (pulse-width)
   - Close or reduce the throttle opening
   - Shift the automatic transmission to a higher gear
2. Applies individual wheel brakes to slow or stop the wheel from spinning. The ABS controller supplies to the wheel brake only the pressure that is required to prevent tire slipping during acceleration. The amount of pressure varies according to the condition of the road surface and the amount of engine power being delivered to the drive wheels. A program inside the controller will disable traction control if brake system overheating is likely to occur.
3. Lights a low traction or traction control warning light on the dash.
   ● **SEE FIGURE 107–13**.

FREQUENTLY ASKED QUESTION

Does Traction Control Engage Additional Drive Wheels?

When the term *traction control* is used, many people think of four-wheel-drive or all-wheel-drive vehicles and power trains. Instead of sending engine torque to other drive wheels, it is the purpose and function of the traction control system to prevent the drive wheel(s) from slipping during acceleration. A slipping tire has less traction than a nonslipping tire—therefore, if the tire can be kept from slipping (spinning), more traction will be available to propel the vehicle. Traction control works with the engine computer to reduce torque delivery from the engine, as well as the controller to apply the brakes to the spinning wheel if necessary to regain traction.

TRACTION ACTIVE LAMP On most applications, a "TRAC CNTL" indicator light or "TRACTION CONTROL ACTIVE" message flashes on the instrumentation when the system is engaging traction control. This helps alert the driver that the wheels are losing traction. In most applications, the message does not mean there is anything wrong with the system—unless the ABS warning lamp also comes on or the traction control light remains on continuously.

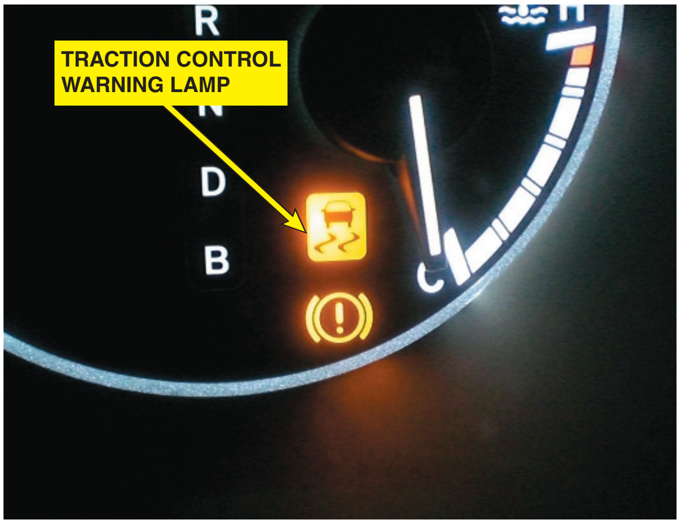

FIGURE 107–13 A traction control or low traction light on the dash is confusing to many drivers. When the lamp is on or flashing, it indicates that a low traction condition has been determined and the traction control system is working to restore traction. A flashing traction dash light does not indicate a fault.

TRACTION DEACTIVATION SWITCH Many vehicles with traction control have a dash-mounted switch that allows the driver to deactivate the system when desired (as when driving in deep snow). An indicator light shows when the system is on or off and may also signal the driver when the traction control system is actively engaged during acceleration.

ESC/TC DIAGNOSIS

STEPS INVOLVED Because the electronic stability control (ESC) and traction control (TC) systems use some of the same sensors and controllers, the diagnosis for them is about the same. To diagnose faults with either system, follow the recommended procedures found in service information. The usual procedure involves the following steps:

STEP 1 **Verify the customer concern (complaint).** This step includes trying to duplicate what the customer or driver is concerned about the system. If the traction control or ESC light is flashing, this indicates that it is trying to bring the vehicle under control. This may be normal operation if the following conditions exist:

- Icy or slippery road conditions
- Worn tires that lack traction

STEP 2 **Perform a thorough visual inspection** including the following:

- Check that all tires are the same size and tread depth.

NOTE: Using a spare tire on the drive wheel could cause the traction control and/or ESC amber warning light to flash because the controller is seeing that the smaller tire is rotating faster than the other side.

STEP 3 **Check service information** for the specified procedure to follow to retrieve diagnostic trouble codes. Most vehicles require the use of a factory-brand scan tool. ● **SEE FIGURE 107–14**.

FIGURE 107–14 The use of a factory scan tool is often needed to diagnose the ESC system.

STEP 4 **Follow the troubleshooting procedure** as specified to fix the root cause of the problem. This means following the instructions displayed on the scan tool or service information. The steps usually include all or many of the following:

- Brake fluid level
- Wheel speed sensor resistance
- Fault with the base brake system, such as air in the lines that could prevent the traction control controller from applying the wheel brakes

STEP 5 **Repair the fault.**

STEP 6 **Road test the vehicle** under the same conditions that were performed to verify the fault to be sure that the fault has been repaired.

TIRES AND WHEELS

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Explain the purpose and functions of tires.
- Identify the parts of a tire.
- Describe how a tire is constructed.
- Discuss tire service descriptions.
- Discuss the uniform tire quality grading system.
- Discuss the DOT tire code.
- Discuss tire conicity and ply steer.
- Describe spare tires.
- Describe run-flat tires.
- Explain the construction and sizing of steel and alloy wheels.
- Describe tire valves.
- Describe lug nuts.

INTRODUCTION TO TIRES

PURPOSE The friction (traction) between the tire and the road determines the handling characteristics of any vehicle. Think about this statement for a second. The compounding, construction, and condition of tires are some of the most important aspects of the steering, suspension, alignment, and braking systems of any vehicle. A vehicle that handles poorly or that pulls, darts, jumps, or steers “funny” may be suffering from defective or worn tires. Understanding the construction of a tire is important for the technician to be able to identify tire failure or vehicle handling problems.

FUNCTION Tires are mounted on wheels that are bolted to the vehicle to provide:

1. Shock absorber action when driving over rough surfaces
2. Friction (traction) between the wheels and the road

All tires are assembled by hand from many different component parts consisting of various rubber compounds, steel, and various types of fabric material. Tires are also available in many different designs and sizes.

PARTS OF A TIRE

TREAD **Tread** refers to the part of the tire that contacts the ground. *Tread rubber* is chemically different from other rubber parts of a tire and is compounded for a combination of traction and tire wear. *Tread depth* is usually 11/32 inch deep on new tires (this could vary, depending on manufacturer, from 9/32 to 15/32 inch). ● **FIGURE 108–1** shows a tread depth gauge.

NOTE: A tread depth is always expressed in 1/32s of an inch, even if the fraction can be reduced to 1/16s or 1/8s.

Wear indicators are also called **wear bars**. When tread depth is down to the legal limit of 2/32 inch bald strips appear across the tread. ● **SEE FIGURE 108–2**.

Tie bars are molded into the tread of most all-season-rated tires. These rubber reinforcement bars are placed between tread blocks on the outer tread rows to prevent unusual wear and to reduce tread noise. As the tire wears normally, the tie bars will gradually appear. This should not be mistaken for an indication of excess outer edge wear. A tire tread with what appears to be a solid band across the entire width of the tread is what the service technician should consider the wear bar indicator.

Grooves are large, deep recesses molded in the tread and separating the tread blocks. These grooves are called *circumferential grooves* or *kerfs.* Grooves running sideways across the tread of a tire are called *lateral grooves.* ● **SEE FIGURE 108–3**.

Grooves in both directions are necessary for wet traction. The trapped water can actually cause the tires to ride up on a layer of water and lose contact with the ground, as shown in ● **FIGURE 108–4**. This is called **hydroplaning**. With worn tires, hydroplaning can occur at speeds as low as 30 MPH on wet roads. Stopping and cornering is impossible when hydroplaning occurs. *Sipes* are small slits in the tread area to increase wet and dry traction.

SIDEWALL The **sidewall** is that part of the tire between the tread and the wheel. The sidewall contains all the size and construction details of the tire.

Some tires turn brown on the sidewalls after a short time. This is due to ozone (atmosphere) damage that actually causes the rubber to oxidize. Premium-quality tires contain an anti-oxidizing chemical additive blended with the sidewall rubber to prevent this discoloration.

WHITE SIDEWALL/LETTERED When pneumatic tires were first constructed in the early 1900s, only natural rubber was used. The entire tire was white. When it was discovered that carbon black greatly increased the toughness of a tire, it was used. The public did not like the change from white tires to black, so tire manufacturers put the carbon black (lamp black) only in the rubber that was to be used for the tread portion of the tire. This tire lasted a lot longer because the black rubber tread that touched the ground was stronger and tougher; it sold well because the sidewalls were white.

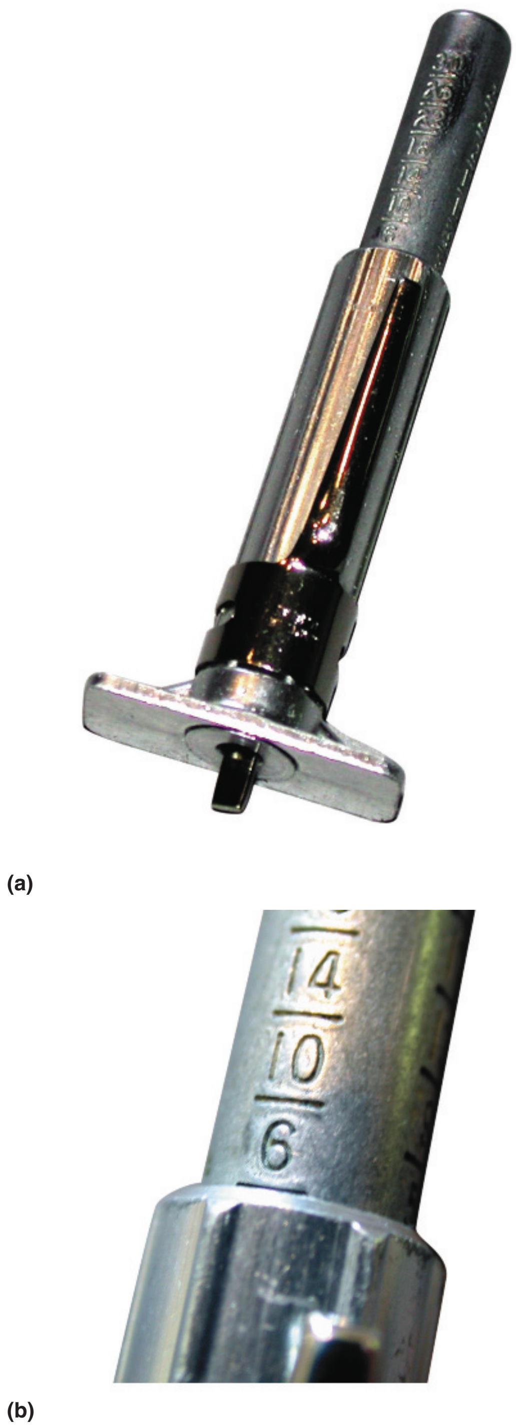

FIGURE 108–1 (a) A typical tire tread depth gauge. The center movable plunger is pushed down into the groove of the tire. (b) The tread depth is read at the top edge of the sleeve. In this example, the tread depth is 6/32 inch.

White sidewall or white lettered tires actually contain a strip of white rubber under the black sidewall. This is ground off at the factory to reveal the white rubber. Only whitewalls or white letter lines contain this expensive white rubber. Various widths of whitewalls are made possible simply by changing the width of the grinding wheel.

BEAD The **bead** is the foundation of the tire and is located where the tire grips the inside of the wheel rim.

1. The bead is constructed of many turns of copper- or bronze-coated steel wire.

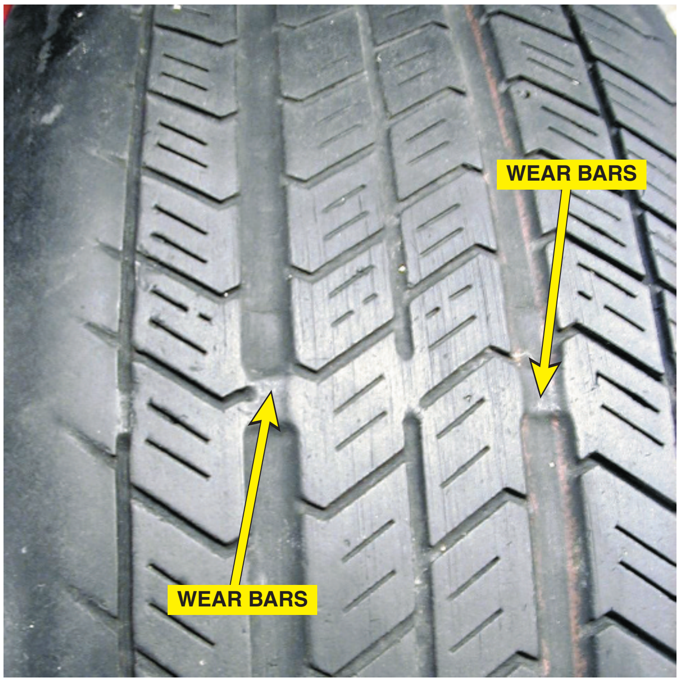

FIGURE 108–2 Wear indicators (wear bars) are strips of bald tread that show when the tread depth is down to 2/32 inch, which is the legal limit in many states.

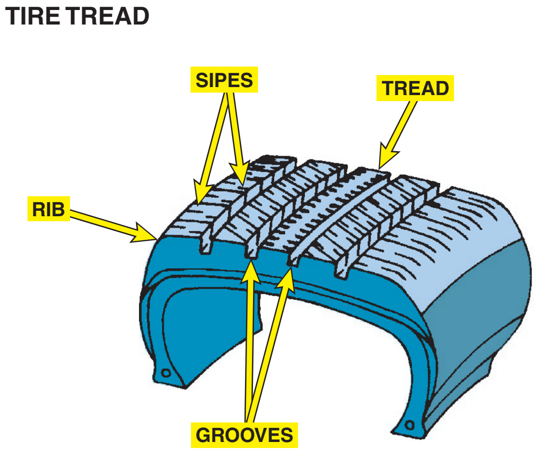

FIGURE 108–3 The tire tread runs around the circumference of the tire, and its pattern helps maintain traction. The ribs provide grip, while the grooves direct any water on the road away from the surface. The sipes help the tire grip the road.

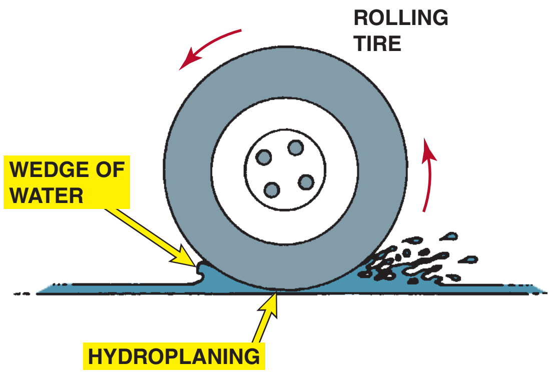

FIGURE 108–4 Hydroplaning can occur at speeds as low as 30 MPH (48 km/h). If the water is deep enough and the tire tread cannot evacuate water through its grooves fast enough, the tire can be lifted off the road surface by a layer of water. Hydroplaning occurs at lower speeds as the tire becomes worn.

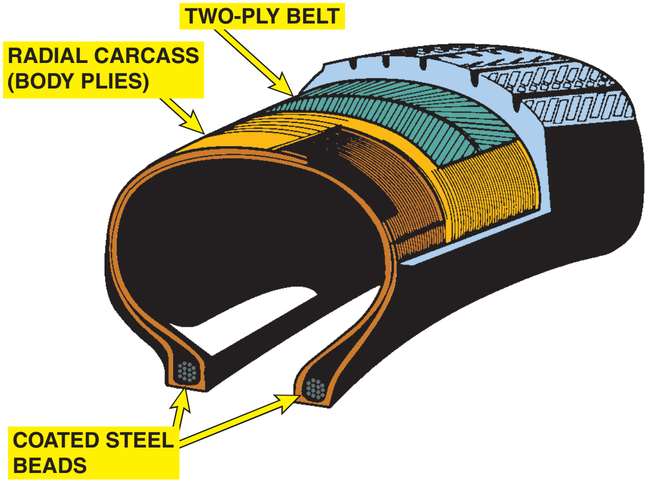

FIGURE 108–5 Typical construction of a radial tire. Some tires have only one body ply, and some tires use more than two belt plies.

2. The main body plies (layers of material) are wrapped around the bead.
3. Most radial-ply tires and all truck tires wrap the bead with additional material to add strength.

CAUTION: If the bead of a tire is cut or damaged, the tire must be replaced!

BODY PLY A tire gets its strength from the layers of material wrapped around both beads under the tread and sidewall rubber. This creates the main framework, or "carcass," of the tire; these **body plies** are often called **carcass plies**. A four-ply tire has four separate layers of material. If the body plies overlap at an angle (bias), the tire is called a *bias-ply* tire. If only one or two body plies are used and they do not cross at an angle, but lie directly from bead to bead, then the tire is called *radial ply*. ● **SEE FIGURE 108–5**.

1. Rayon is a body ply material used in many tires because it provides a very smooth ride. A major disadvantage of rayon is that it rots if exposed to moisture.
2. Nylon is a strong body ply material. Though it is still used in some tires, it tends to "flat-spot" after sitting overnight.
3. Aramid is the generic name for aromatic polyamide fibers developed in 1972. Aramid is several times stronger than steel (pound for pound) and is used in high-performance-tire construction. Kevlar is the DuPont brand name for aramid and a registered trademark of E.I. DuPont de Nemours and Co.
4. Polyester is the most commonly used tire material because it provides the smooth-ride characteristics of rayon with the rot resistance and strength of nylon.

BELT A tire **belt** is two or more layers of material applied over the body plies and under the tread area only to stabilize the tread and increase tread life and handling.

1. Tire belts can consist of the following materials:
   a. Steel mesh
   b. Nylon
   c. Rayon
   d. Fiberglass
   e. Aramid
2. All radial tires are belted.

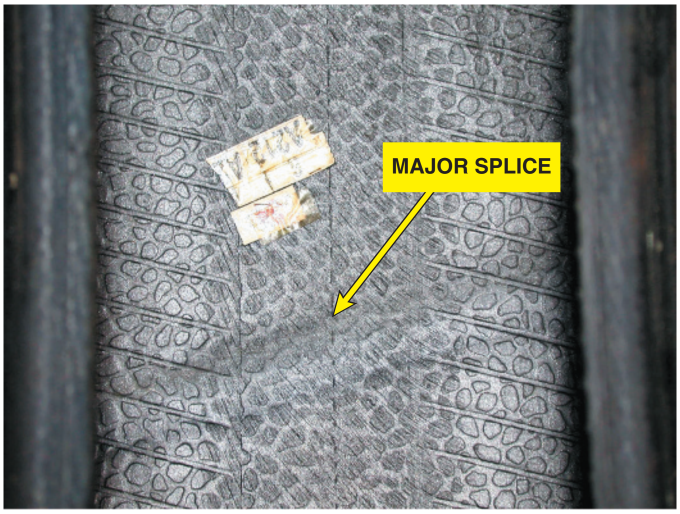

FIGURE 108–6 The major splice of a tire can often be seen and felt on the inside of the tire. The person who assembles (builds) the tire usually places a sticker near the major splice as a means of identification for quality control.

NOTE: Most tires rated for high speed use a nylon "overlay" or "cap belt" between the two-ply belt and the tread of the tire. This overlay helps stabilize the belt package and helps hold the tire together at high speeds, when centrifugal force acts to tear a tire apart.

INNER LINER The **inner liner** is the soft rubber lining (usually a butyl rubber compound) on the inside of the tire that protects the body plies and helps provide for self-sealing of small punctures.

MAJOR SPLICE When the tire is assembled by a craftsperson on a tire-building machine, the body plies, belts, and tread rubber are spliced together. The fabric is overlapped approximately five threads. The point where the majority of these overlaps occur is called the **major splice**, which represents the stiffest part of the tire. This major splice is visible on most tires on the inside, as shown in ● **FIGURE 108–6**.

NOTE: On most new vehicles and/or new tires, the tire manufacturer paints a dot on the sidewall near the bead, indicating the largest diameter of the tire. The largest diameter of the tire usually is near the major splice. The wheel manufacturer either marks the wheel or drills the valve core hole at the smallest diameter of the wheel. Therefore, the dot should be aligned with the valve core or marked for best balance and minimum radial runout.

TIRE MOLDING

After the tire has been assembled by the tire building machine, it is called a **green tire**. ● **SEE FIGURE 108–7**. At this stage in construction, the rubber can be returned and reused because it has not been changed chemically. The completed green tire is then placed in a mold where its shape, tread design, and all sidewall markings are formed. ● **SEE FIGURE 108–8**.

While in the mold, a steam bladder fills the inside of the tire and forces the tire against the outside of the mold. After approximately 30 minutes at 300°F (150°C), the heat changes the chemistry of the rubber. The tire is no longer called a green tire but a *cured tire,* and after inspection and cleaning, it is ready for shipment.

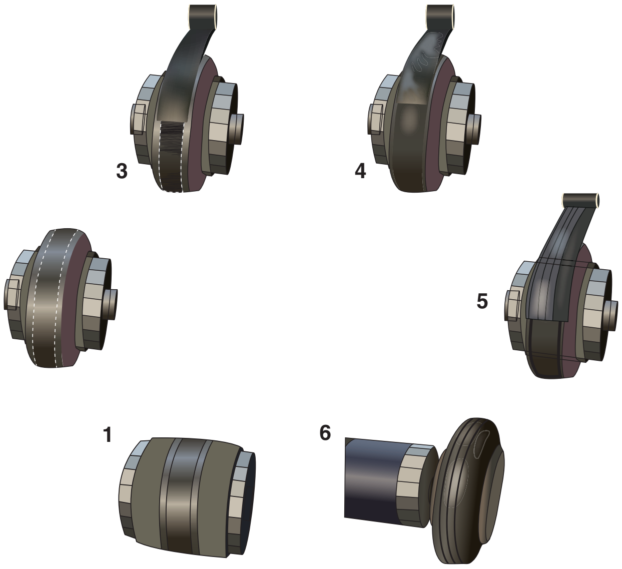

FIGURE 108–7 Complete stage 1 (body plies, sidewall components, and beads). 2. Building drum expands in preparation to receive the belts and tread. 3. Application of belt #1. 4. Application of belt #2. 5. Application of the tread. 6. Drum retracts to release the completed green (uncured) tire.

Some tires use letters at the end of the tire size (suffixes) to indicate special applications, including the following:

LT	light truck
ML	mining and logging
MH	mobile home
ST	special trailer
TR	truck

FREQUENTLY ASKED QUESTION

Why Do I Get Shocked by Static Electricity When I Drive a Certain Vehicle?

Static electricity builds up in insulators due to friction of the tires with the road. Newer tires use silica and contain less carbon black in the rubber, which makes the tires electrically conductive. Because the tires cannot conduct the static electricity to the ground, it builds up inside the vehicle and is discharged through the body of the driver and/or passenger whenever the metal door handle is touched.

NOTE: Toll booth operators report being shocked by many drivers as money is being passed between the driver and the toll booth operator.

Newer tire sidewall designs that use silica usually incorporate carbon sections that are used to discharge the static electricity to ground. To help reduce the static charge buildup, spray the upholstery with an antistatic spray available at discount and grocery stores.

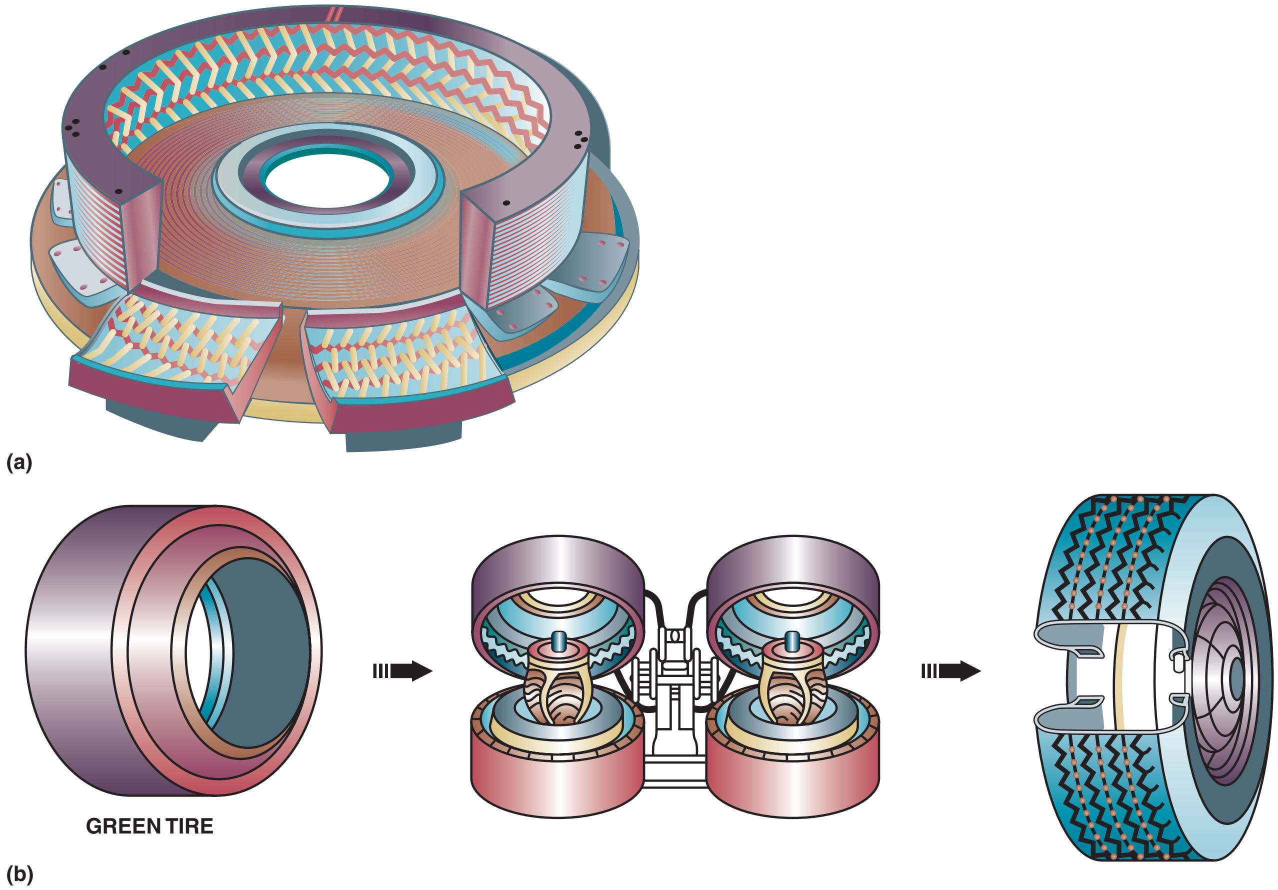

FIGURE 108–8 After the entire tire has been assembled into a completed "green" tire, it is placed into a tire-molding machine where the tire is molded into shape and the rubber is changed chemically by the heat. This nonreversible chemical reaction is called vulcanization. (a) A segmented-type mold (b) A clamshell-type mold showing the steam-filled bladder that inflates which forces the green tire into the mold.

FREQUENTLY ASKED QUESTION

How Much Does Tire Pressure Change with a Change in Temperature?

As the temperature of a tire increases, the pressure inside the tire also increases. The general amount of pressure gain (when temperatures increase) or loss (when temperatures decrease) is as follows:

10°F increase causes 1 PSI increase

10°F decrease causes 1 PSI decrease

For example, if a tire is correctly inflated to 35 PSI when cold and then driven on a highway, the tire pressure may increase 5 PSI or more.

CAUTION: DO NOT LET AIR OUT OF A HOT TIRE! If air is released from a hot tire to bring the pressure down to specifications, the tire will be *underinflated* when the tire has cooled. The tire-pressure specification is for a cold tire.

Always check the tire pressures on a vehicle that has been driven fewer than 2 miles (3.2 km).

Air pressure in the tires also affects fuel economy. If all four tires are underinflated (low on air pressure), fuel economy is reduced about **0.1 mile per gallon (mpg) for each 1 PSI low**. For example, if all four tires were inflated to 25 PSI instead of 35 PSI, not only is tire life affected but fuel economy is reduced by about 1 mile per gallon (10 × 0.1 = 1 mpg).

SERVICE DESCRIPTION

Tires built after 1990 use a "service description" method of sidewall information in accordance with ISO 4000 (International Standards Organization) that includes size, load, and speed rating together in one easy-to-read format. ● **SEE FIGURE 108–9**.

P-Metric Designation	Service Description
P205/75HR × 15	205/75R × 15 92H
P passenger vehicle	205 cross-sectional width in mm
205 cross-sectional width in mm	75 aspect ratio
75 aspect ratio	R radial construction
H speed rating (130 MPH/210 km/h)	15 rim diameter in inches
R radial construction	92 load index
15 rim diameter in inches	H speed rating (130 MPH/210 km/h)

HIGH-FLOTATION TIRE SIZES **High-flotation tires** for light trucks are designed to give improved off-road performance on sand, mud, and soft soil and still provide acceptable hard-road surface performance. These tires are usually larger than conventional tires and require a wider-than-normal

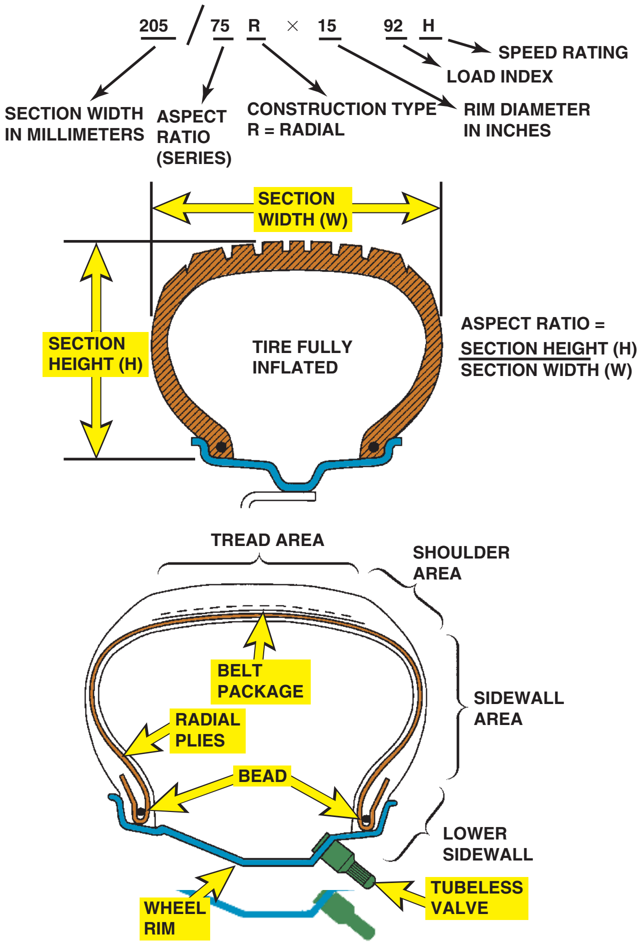

FIGURE 108–9 (a) Tire size designation includes cross-sectional width and aspect ratio. The aspect ratio is the proportional relationship between the width and the height of the tire expressed as a percentage. (b) Cross-sectional view of a typical tire showing the terminology.

FREQUENTLY ASKED QUESTION

What Effect Does Tire Size Have on Overall Gear Ratio?

Customers often ask what effect changing tire size has on fuel economy and speedometer readings. If larger (or smaller) tires are installed on a vehicle, many other factors also will change. These include the following:

1. **Speedometer reading.** If larger-diameter tires are used, the speedometer will read slower than you are actually traveling. This can result in speeding tickets!
2. **Odometer reading.** Even though larger tires are said to give better fuel economy, just the opposite can be calculated! Since a larger-diameter tire travels farther than a smaller-diameter tire, the larger tire will cause the odometer to read a shorter distance than the vehicle actually travels. For example, if the odometer reads 100 miles traveled on tires that are 10% oversized in circumference, the actual distance traveled is 110 miles.
3. **Fuel economy.** If fuel economy is calculated on miles traveled, the result will be *lower* fuel economy than for the same vehicle with the original tires.

$$\text{Calculation: MPH} = \frac{\text{RPM} \times \text{diameter} \times 3.14}{\text{gear ratio}}$$

$$\text{RPM} = \frac{\text{MPH} \times \text{gear ratio}}{\text{diameter} \times 3.14}$$

$$\text{gear ratio} = \frac{\text{RPM} \times \text{diameter} \times 3.14}{\text{MPH}}$$

FREQUENTLY ASKED QUESTION

How Much Bigger Can I Go?

Many owners think they can improve their vehicle by upgrading the tire size over the size that comes from the factory to make their vehicle look sportier and ride and handle better. When changing tire size, there are many factors to consider:

1. The tire should be of the same outside diameter as the original to maintain the proper suspension, steering, and ride height specifications.
2. Tire size affects vehicle speed sensor values, ABS brake wheel sensor values that can change automatic transmission operation, and ABS operation.
3. The tire should not be so wide as to contact the inner wheel well or suspension components.
4. Generally, a tire that is 10 mm wider is acceptable. For example, an original equipment tire size 205/75 × 15 (outside diameter = 27.1 in.) can be changed to 215/75 × 15 (outside diameter = 27.6 in.). This much change is less than 1/2 inch in width and increases the outside diameter by 1/2 inch.

NOTE: Outside diameter is calculated by adding the wheel diameter to the cross-sectional height of the tire, multiplied by 2. ● SEE FIGURE 108–10.

5. Whenever changing tires, make sure that the load capacity is the same or greater than that of the original tires.
6. If wider tires are desired, a lower aspect ratio is required to maintain the same, or close to the same, overall outside diameter of the tire.

Old	New
P205/75 × 15	P215/70 × 15
205 × 0.75 = 154 mm	215 × 0.70 = 151 mm

Notice that the overall sidewall height is generally maintained.

If even larger tires are needed, then 225/60 × 15s may be OK—let's check the math:

$$225 \times 0.60 = 135 \text{ mm}$$

Notice that this is much too short a sidewall height when compared with the original tire.

7. Use the "plus 1" or "plus 2" concept. When specifying wider tires, the sidewall height must be reduced to maintain the same, or close to the same, original equipment specifications. The "plus 1" concept involves replacing the wheels with wheels 1 in. larger in diameter to compensate for the lower aspect of wider tires.

Original	Plus 1
205/75 × 15	225/60 × 16

The overall difference in outside diameter is only 0.5 inch, even though the tire width has increased from 205 to 225 mm and the wheel diameter has increased by 1 inch. If money is no object and all-out performance is the goal, a “plus 2” concept can also be used (use a P245/50 × 17 tire and change to 17 inch diameter wheels).

Here the overall diameter is within 1/20 inch of the original tire/wheel combination, yet the tire width is 1.6 inches (40 mm) wider than the original tire. Refer to the section “Wheels” later in this chapter for proper wheel back spacing and offset when purchasing replacement wheels.

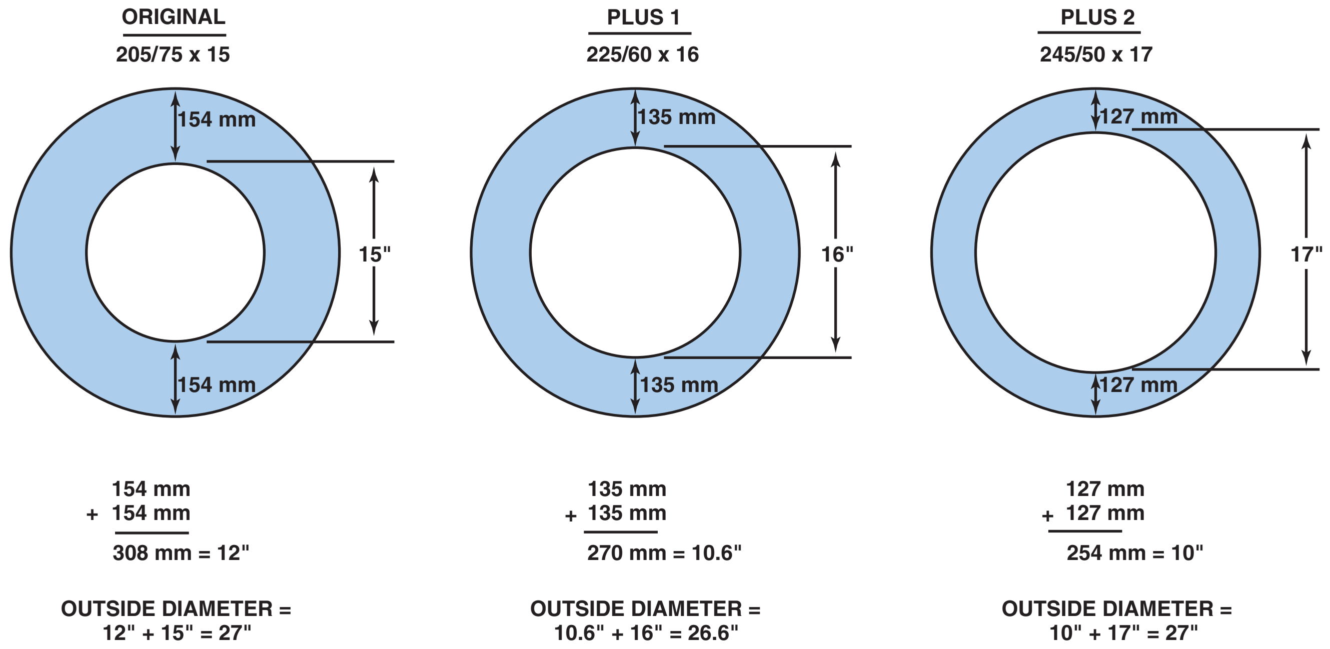

FIGURE 108–10 Notice that the overall outside diameter of the tire remains almost the same and at the same time the aspect ratio is decreased and the rim diameter is increased.

LOAD INDEX AND EQUIVALENT LOADS

The **load index**, as shown in ● **FIGURE 108–11**, is an abbreviated method to indicate the load-carrying capabilities of a tire. The weights listed in the chart represent the weight that *each tire* can safely support. Multiply this amount by 4 to get the maximum that the vehicle should weigh fully loaded with cargo and passengers.

SPEED RATINGS

Tires are rated according to the maximum *sustained* speed. A vehicle should never be driven faster than the **speed rating** of the tires. ● **SEE CHART 108–1**.

CAUTION: A high-speed rating does not guarantee that the tires will not fail, even at speeds much lower than the rating. Tire condition, inflation, and vehicle loading also affect tire performance.

As the speed rating of a tire increases, fewer compromises exist for driver comfort and low noise level. The higher speed rating does not mean a better tire. To survive, a high-speed tire must be built with stiff tread compounds, reinforced body (carcass) construction, and fabric angles that favor high speed and high performance over other considerations. For example, a V-rated tire often has less tread depth than a similar tire with an H-speed rating, and therefore will often not give as long of a service life. Since the speed ratings were first developed in Europe, the letters correspond to metric speed in kilometers per hour, with a conversion to miles per hour as noted.

TIRE PRESSURE AND TRACTION

All tires should be inflated to the specifications given by the vehicle manufacturer. Most vehicles have recommended tire inflation figures written in the owner’s manual or on a placard or sticker on the door post or glove compartment. ● **SEE FIGURE 108–12**.

The pressure number molded into the sidewall of a tire should be considered the maximum pressure when the tire is cold. (Pressures higher than that stated on the sidewall may be measured on a hot tire.)

RIM WIDTH AND TIRE SIZE

The **rim width** is the distance between the tire flanges sometimes called the “flange-to-flange” width. As a general rule, for a given rim width it is best not to change tire width more than 10 mm (either wider or narrower).

FIGURE 108–12 A typical door placard used on a General Motors vehicle indicating the recommended tire inflation. Note that the information also includes the size and speed rating of the tire as well as the recommended wheel size.

For a given tire width, it is best not to vary rim width more than 1/2 inch in either direction. For example, if the original tire size is 195/70 × 14, then either a 185/70 × 14 (−10 mm) or a 205/70 × 14 (+10 mm) *could* be used on the original rim (wheel) without undue harm *if* the replacement tire has proper clearance with the body and suspension components.

Installing a tire on too narrow a wheel will cause the tire to wear excessively in the center of the tread. Installing a tire on too wide a wheel will cause excessive tire wear on both edges.

UNIFORM TIRE QUALITY GRADING SYSTEM

The U.S. Department of Transportation and the National Highway Traffic Safety Administration developed a system of tire grading, the **Uniform Tire Quality Grading System (UTQGS)**, to help customers better judge the relative performance of tires. The three areas of tire performance are tread wear, traction, and temperature resistance, as shown in ● **FIGURE 108–13**.

NOTE: All tires sold in the United States must have UTQGS ratings molded into the sidewall.

TREAD WEAR The tread wear grade is a comparison rating based on the wear rate of a standardized tire, tested under carefully controlled conditions, which is assigned a value of 100. A tire rated 200 should have a useful life twice as long as the standard tire's.

NOTE: The standard tire has a rating for tread wear of 100. This value has generally been accepted to mean a useful life of 20,000 miles of normal driving. Therefore, a tire rated at 200 could be expected to last 40,000 miles.

Tread Wear Rating Number	Approximate Number of mi/km
100	20,000/32,000
150	30,000/48,000
200	40,000/64,000
250	50,000/80,000
300	60,000/96,000
400	80,000/129,000
500	100,000/161,000

The tread wear life of any tire is affected by driving habits (fast stops, starts, and cornering will decrease tread life), tire rotation (or lack of tire rotation), inflation, wheel alignment, road surfaces, and climate conditions.

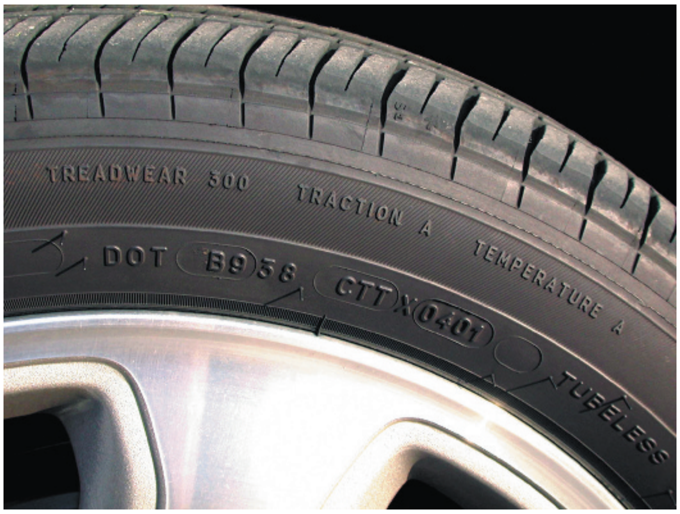

FIGURE 108–13 Typical "Uniform Tire Quality Grading System" (UTQGS) ratings imprinted on the tire sidewall.

TRACTION Traction performance is rated by the letters AA, A, B, and C, with AA being the highest.

NOTE: The traction rating is for wet braking distance only! It does not include cornering traction or dry braking performance.

The traction rating is only one of many other factors that affect wet braking traction, including air inflation, tread depth, vehicle speed, and brake performance.

TEMPERATURE RESISTANCE Temperature resistance is rated by the letters A, B, and C, with A being the highest rating. Tires generate heat while rotating and flexing during normal driving conditions. A certain amount of heat buildup is desirable because tires produce their highest coefficient of traction at normal operating temperatures. For example, race car drivers frequently swerve their cars left and right during the pace laps, causing increased friction between the tire and the road surface, which warms their tires to operating temperature. However, if temperatures rise too much, a tire can start to come apart—the oils and rubber in the tire start to become a liquid! Grade C is the minimum level that all tires must be able to pass under the current Federal Motor Vehicle Safety Standard No. 109.

M&S RATING Most all-season tires are rated and labeled as *M & S*, *MS*, or *M + S*, and therefore must adhere to general

FREQUENTLY ASKED QUESTION

What Type of Tires Should Be Used and When?

Owners of vehicles are often confused when it comes to replacing tires. Unless the rims (wheels) have been replaced with ones of a different size than the vehicle originally came with, the information needed can be found either in the owner's manual or on a sticker on the driver's door jamb. The four things that need to be checked when replacing tires include

1. **The correct size.** A tire size describes the width of the tire, the height of the sidewall, and the rim diameter. This should be the same size that was originally on the vehicle.
2. **Speed rating.** The speed rating is given as a letter (Q, T, S, H, V, W, and Y) and should be the same as the original tires that came with the vehicle.
3. **The load rating.** This is especially important when tires are being purchased for a pickup truck or SUV where a full load may be carried. Check the load rating on the sidewall of the tires to make sure that they match or exceed the load rating of the original tires. The load rating is given as a number in combination with the speed rating (i.e., 93 V) and together is known as the "service description" of the tire.
4. **Summer, Winter, or All-Season-Summer tires.** If the vehicle will be driven in a climate that is above 45°F (7°C), then summer-type tires can be used.
    - **Winter tires.** If the vehicle is going to be driven in winter conditions at temperatures always below 45°F (7°C), then winter tires should be selected.
    - **All-season tires.** If the vehicle will be driven under a variety of conditions and both above and below 45°F (7°C), then all-season type tires should be selected.

design features as specified by the Rubber Manufacturers Association (RMA).

Tires labeled M & S are constructed with an aggressive tread design, as well as tread compounds and internal construction that are designed for mud and snow. One design feature is that the tire has at least 25% void area. This means that the tread blocks have enough open space around them to allow the blocks to grab and clean themselves of snow and mud. Block angles, dimensional requirements, and minimum cross-sectional width are also a requirement for the M & S designation.

The tread rubber used to make all-season tires is also more flexible at low temperatures. This rubber compound is low-bounce (called high-hysteresis) and is more likely to remain in contact with the road surface. The rubber compound is also called *hydrophilic*, meaning that the rubber has an affinity for water (rather than being *hydrophobic* rubber, which repels water).

NOTE: Most vehicle manufacturers recommend that the same *type* of tire be used on all four wheels even though the size of the tire may vary between front and rear on some high-performance vehicles. Therefore, if all-season replacement tires are purchased, a complete set of four should be used to be assured of proper handling and uniform traction characteristics. While *tire* manufacturers have been recommending this for years—since the late 1980s—most *vehicle* manufacturers are also recommending that all four tires be of the same construction and tread type to help ensure proper vehicle handling.

FOUR SEASONS TIRES This is a new category created by tire companies. Four seasons tires are the same as all-season tires except most of these are also three-peak mountain snowflake (3PMSF) rated. They have minimum snow traction ability tested versus an industry standard reference test tire (SRTT)—minimum 110 rating.

The three-mountain snowflake rated tires are required to be installed on vehicles in many states and provinces during the winter months, usually December 15 to March 15. ● **SEE FIGURE 108–14**. For reference, most all-season tires have a traction rating of 70-80, so this means that the four-season tires offer more traction on snow.

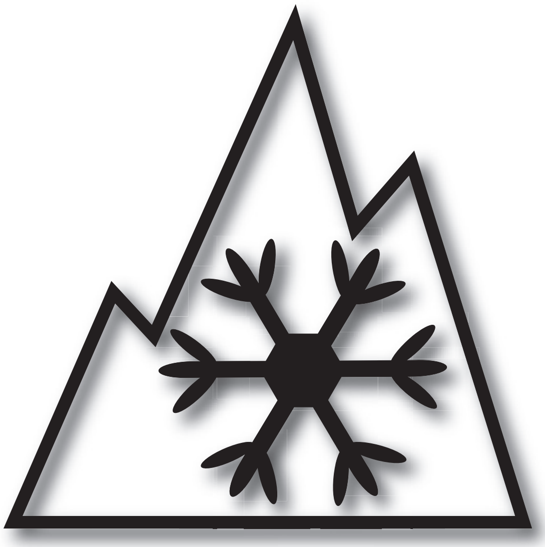

FIGURE 108–14 The three-mountain peak symbol indicates that the tire is rated with the necessary snow traction to be the specified winter tire required in some states and Canadian provinces for use in the winter months.

ALL-TERRAIN AND PERFORMANCE TIRES All -terrain (A/T) designates a performance category for marketing differentiation, not actual performance rating. Other names used by marketing without actual test specifications include

- Touring-Usually an all-season tire and often include an asymmetrical tread pattern.
- All-season High Performance (AS HP).
- Mud-terrain (M/T) tires. The tire is designed to handle both off and on road driving.
- Highway-terrain (H/T) tires. H/T tires allow a driver to use the same tires for everyday highway driving as well occasional off-road driving.

DOT TIRE CODE

All tires sold in the United States must be approved by the U.S. Federal Department of Transportation (DOT). The **DOT tire code** requirements include resistance to tire damage that could be caused by curbs, chuckholes, and other common occurrences for a tire used on public roads.

NOTE: Most race tires are *not* DOT-approved and must never be used on public streets or highways.

Each tire that is DOT-approved has a DOT number molded into the sidewall of the tire. This number is usually imprinted on only one side of the tire and is usually on the side *opposite the whitewall*. The DOT code includes letters and numbers, such as **MJP2CBDX264.**

The first two letters identify the manufacturer and location. For this example, the first two letters (MJ) mean that the tire was made by the Goodyear Tire and Rubber Company in Topeka, Kansas. The last three numbers are the build date code, which is the year (1994),

CASE STUDY

Tire Date Code Information Saved Me Money!

This author was looking at a three-year-old vehicle and noticed that the right rear tire had a build date code newer than the vehicle. I asked the owner, "How badly was this vehicle hit?" The owner stumbled and stuttered a little, then said, "How did you know that an accident occurred?" I told the owner that the right rear tire, while the exact same tire as the others, had a date code indicating that it was only one year old, whereas the original tires were the same age as the vehicle.

The owner immediately admitted that the vehicle slid on ice and hit a curb, damaging the right rear tire and wheel. Both the tire and wheel were replaced and the alignment checked. The owner then dropped the price of the vehicle $500!

Summary:

Complaint—buyer of a used car noticed that one tire was newer than the others.
Cause—The owner admitted that the vehicle had slid off the road and hit a curb causing damage to the wheel and tire.
Correction—Because the perspective buyer knew the date code, and mentioned this to the seller, the purchase price was reduced saving the buyer money.

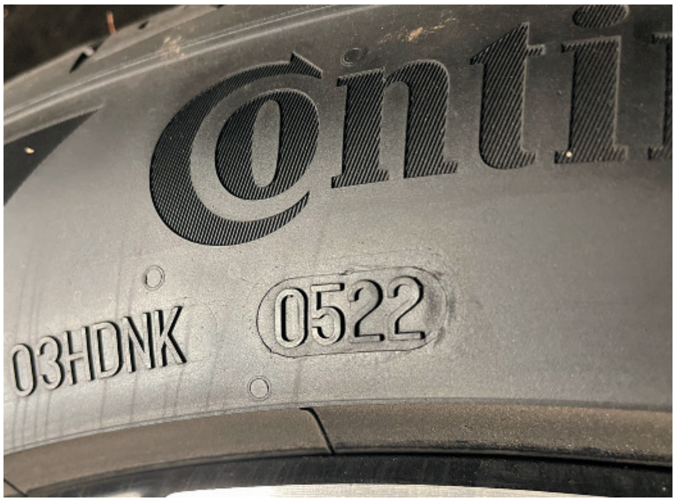

FIGURE 108–15 Typical DOT date code. This tire was built in the 5th week of 2022. While there is no official standard for replacement intervals for tires, many experts recommend that tires be replaced, regardless of thread depth, when they are older than ten years.

and the 26 means that it was built during the 26th week of 1994. Starting with tires manufactured after January 1, 2000, the tire build date includes four digits rather than three digits. A new code such as "3406" means the 34th week of 2006. ● **SEE FIGURE 108–15**.

TIRE CONICITY AND PLY STEER

Tire **conicity** can occur during the construction of any radial or belted tire when the parts of the tire are badly positioned, causing the tire to be smaller in diameter on one side. When this tire is installed on a vehicle, it can cause the vehicle to pull to one side of the road due to the cone shape of the tire. ● **SEE FIGURE 108–16**.

Since the cause of conicity is due to the construction of the tire itself, there is nothing the service technician can do to correct the condition. The exact cause of the conicity is generally due to the slight movement of the belt and tread in the mold during inflation. If a vehicle pulls to one side of the road, the service technician should switch tires left to right (left-side tires to the right side and right-side tires to the left side of the vehicle). If this swap of tires corrects the pulling condition, then tire conicity was the possible cause.

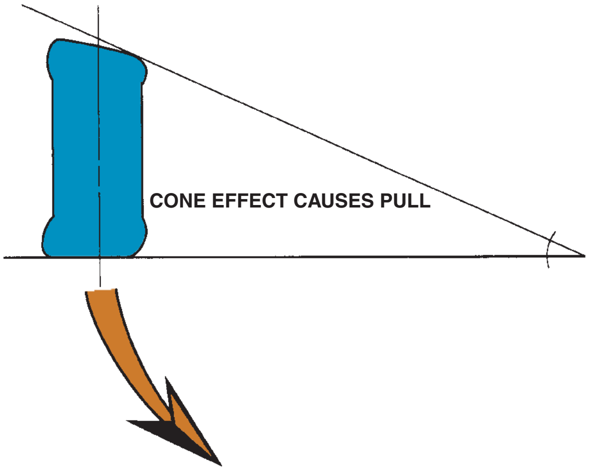

FIGURE 108–16 Conicity is a fault in the tire that can cause the vehicle to pull to one side due to the cone effect (shape) of the tire.

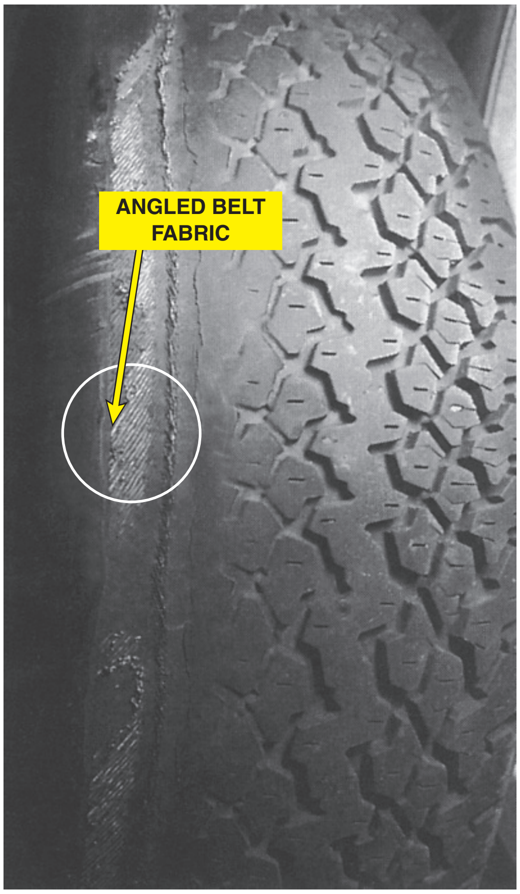

FIGURE 108–17 Notice the angle of the belt material in this worn tire. The angle of the belt fabric can cause a "ply steer" or slight pulling force toward one side of the vehicle.

NOTE: *Radial pull* or *radial tire pull* are other terms often used to describe tire conicity.

Ply steer is another term that describes a slight pulling force on a vehicle due to tire construction. Ply steer is due to the angle of the cords in the belt layers, as seen in ● **FIGURE 108–17**, and not in the ply layer of the carcass (body), as the name implies. Ply steer will cause a slight drift regardless of its direction of rotation. Switching tires left to right will *not* correct a ply steer condition.

NOTE: Whenever a wheel and tire assembly is switched from one side of a vehicle to the other, the tire revolves in the opposite direction.

Ply steer is built into the tire during construction. There is nothing a service technician can do to correct ply steer, except to compensate for it with alignment angles or replace the tire.

SPARE TIRES

Most vehicles today come equipped with space-saver spare tires that are smaller than the wheels and tires that are on the vehicle. The reason for the small size is to reduce the size and weight of the entire vehicle and to increase fuel economy by having the entire vehicle weigh less by not carrying a heavy spare tire and wheel around. The style and type of these spare tires have changed a great deal over the last several years, and different makes and types of vehicles use various types of spare tires.

CAUTION: Before using a spare tire, always read the warning label (if so equipped) and understand all use restrictions. For example, some spare tires are not designed to exceed 50 MPH (80 km/h) or be driven more than 500 miles (800 km).

Many small, space-saving spare tires use a higher-than-normal air inflation pressure, usually 60 PSI (414 kPa). Even though the tire often differs in construction, size, diameter, and width from the vehicle's original tires, it is amazing that the vehicle usually handles the same during normal driving. Obviously, these tires are not constructed with the same durability as a full-size tire and should be removed from service as soon as possible.

NOTE: When was the last time you checked the tire pressure in your spare tire? The spare tire pressure should be checked regularly.

RUN-FLAT TIRES

Run-flat tires (abbreviated RFT) are designed to operate without any air for a limited distance (usually 50 miles at 55 MPH). This feature allows vehicle manufacturers to build vehicles without the extra room and weight of a spare tire and jack assembly.

A typical run-flat tire (also called *extended mobility tire* [EMT] or *zero pressure* [ZP] *tire*) requires the use of an air pressure sensor/transmitter and a dash-mounted receiver to warn the driver that a tire has lost pressure. Because of the reinforced sidewalls, the vehicle handles almost the same with or without air pressure. ● **SEE FIGURES 108–18 AND 108–19**.

CAUTION: Tire engineers warn that rapid cornering should be avoided if a run-flat tire has zero air pressure. The handling during quick maneuvers is often unpredictable and could be dangerous.

WHEELS

The concept of a wheel has not changed in the last 5,000 years, but the style and materials used have changed greatly. Early automotive wheels were constructed from wood with a steel band as the tire.

Today's wheels are constructed of steel or aluminum alloy. The center section of the wheel that attaches to the hub is called the **center section** or **spider** because early wheels used wooden spokes that resembled a spider's web. The rubber tire attaches to the rim of the wheel. The rim has two *bead flanges* where the bead of the tire is held against the wheel when the tire is inflated. The shape of this flange is very important and is designated by Tire and Rim Association letters. For example, a wheel designated 14 × 6JJ means that the diameter of the wheel is 14 inch and the wheel is 6 inch wide measured from inside to inside of the flanges. The letters JJ indicate the *exact* shape of the flange area. ● **SEE FIGURE 108–20**. This flange area shape and the angle that the rim drops down from the flange are important because of the following reasons:

- They permit a good seal between the rim and the tire.
- They help retain the tire on the rim in the event of loss of air. This is the reason why modern wheels are called "safety rim wheels." ● **SEE FIGURE 108–21**.
- Run-flat tires (tires that are designed to operate without air for a limited distance without damage) often require a specific wheel rim shape.

WHEEL OFFSET

Offset is a very important variable in wheel design. If the center section (spider) is centered on the outer rim, the offset is zero. Wheel offset is often referred to as ET, which stands for *Einpress Tieffe* in German. ● **SEE FIGURE 108–22**.

POSITIVE OFFSET The wheel has a positive offset if the center section is outward from the wheel centerline. Front-wheel-drive vehicles commonly use positive-offset wheels to improve the loading on the front wheels and to help provide for a favorable scrub radius.

NEGATIVE OFFSET The wheel has a negative offset if the center section is inboard (or “dished”) from the wheel centerline. ● **SEE FIGURE 108–23**. Avoid using replacement wheels that differ from the original offset.

BACK SPACING

Back spacing, also called *rear spacing* or *backside setting,* is the distance between the back rim edge and the wheel center section mounting pad. *This is not the same as offset.* Back spacing can be measured directly with a ruler, as shown in ● **FIGURE 108–24**.

DETERMINING BOLT CIRCLE

On four-lug axles and wheels, the **bolt circle** measurement is simply taken from center to center on opposite studs or holes, as shown in ● **FIGURE 108–25**.

On five-lug axles and wheels, it is a little harder to determine bolt circle. One method is to measure from the far edge of one bolt hole to the center of the hole two over from the first, as shown in ● **FIGURE 108–26**. Another method for a five-lug wheel is to measure from center to center between two adjacent studs and convert this measurement into bolt circle diameter, as in the following chart. ● **SEE FIGURE 108–27**.

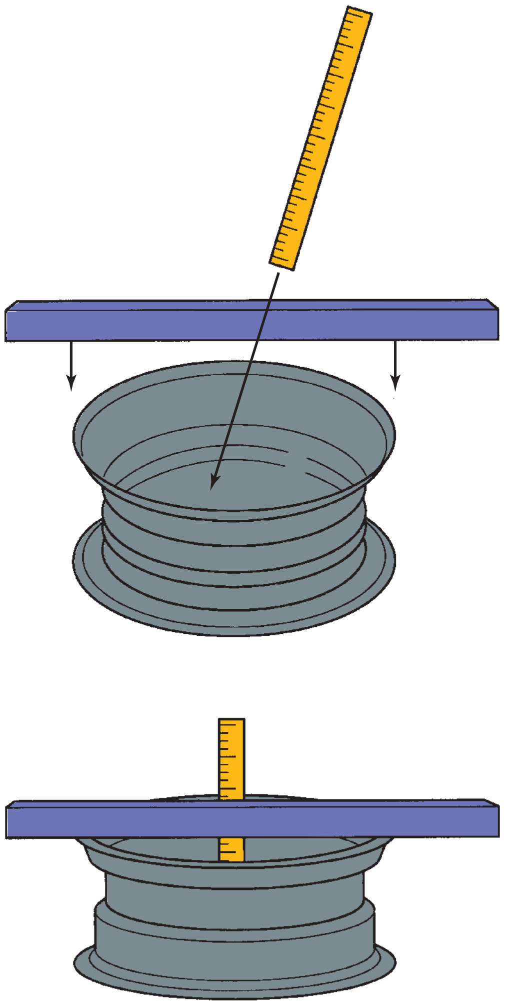

FIGURE 108–24 Back spacing (rear spacing) is the distance from the mounting pad to the edge of the rim. Most custom wheels use this measurement method to indicate the location of the mounting pad in relation to the rim.

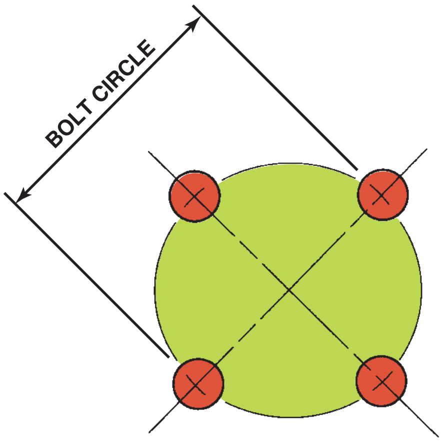

FIGURE 108–25 Bolt circle is the diameter of a circle that can be drawn through the center of each lug hole or stud. The bolt circle is sometimes referred to as PCD for pitch circle diameter.

FIGURE 108–26 Measuring the bolt circle on a five-lug wheel is difficult, but a quick and easy way includes measuring as shown to determine the approximate bolt circle of a five-lug wheel.

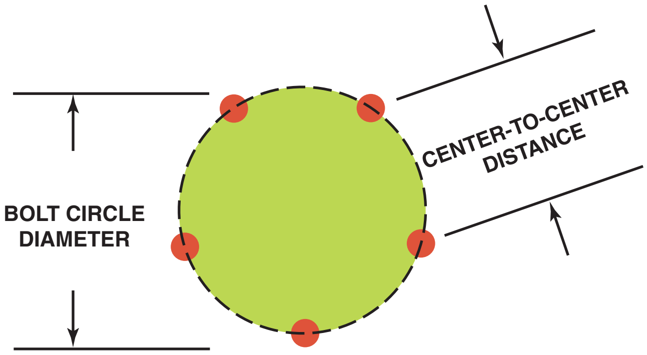

FIGURE 108–27 Measure center-to-center distance and compare the distance to the figures in the chart in the text to determine the diameter for a five-lug bolt circle.

STEEL WHEELS Steel is the traditional wheel material. A steel wheel is very strong due to its designed shape and the fact that it is *work hardened* during manufacturing. In fact, most of the strength of a steel wheel is due to its work hardening. Painting and baking cycles also increase the strength of a steel wheel. Steel wheels are formed from welded hoops that are flared and joined to stamped spiders.

ALUMINUM WHEELS Forged and cast aluminum wheels are commonly used on cars and trucks. *Forged* means that the aluminum is hammered or forged under pressure into shape. A forged aluminum wheel is much stronger than a *cast* aluminum wheel.

A cast aluminum wheel is constructed by pouring liquid (molten) aluminum into a mold. After the aluminum has cooled, the

FREQUENTLY ASKED QUESTION

What Does This Mark in a Wheel Mean?

The symbol **JWL**, for Japan Wheel Light Metal, means that the wheel meets the technical standards for passenger-car light-alloy disc wheels. See the mark in ● **FIGURE 108–28**.

The manufacturer is responsible for conducting the inspections set forth in the technical standard, and the JWL mark is displayed on those products that pass the inspection.

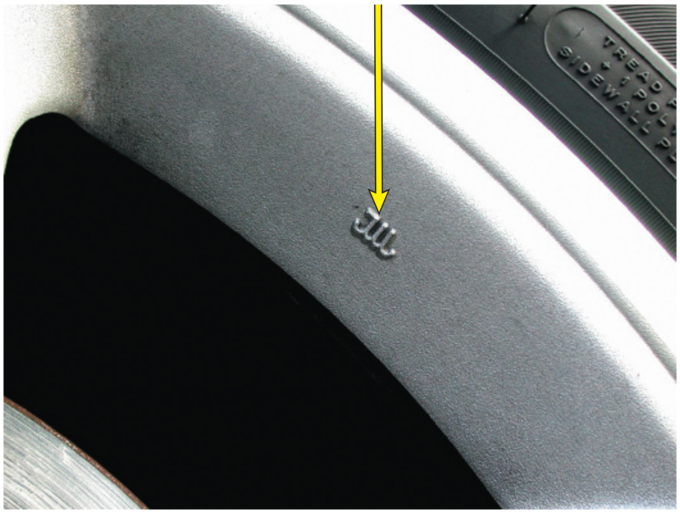

FIGURE 108–28 A typical JWL symbol for the Japan Wheel Light Metal standard mark.

cast aluminum wheel is removed from the mold and machined. Aluminum wheels are usually thicker than steel wheels and require special wheel weights when balancing. Coated or covered wheel weights should be used when balancing aluminum wheels to prevent galvanic corrosion damage to the wheel. Most aluminum wheels use an alloy of aluminum. Aluminum can be combined (alloyed) with copper, manganese, silicon, or other elements to achieve the physical strength and characteristics for the exact product. Aluminum alloy wheels are often called alloy wheels.

Some racing wheels are made from a lighter-weight metal called magnesium. These wheels are called *mag* wheels (an abbreviation for *magnesium*). True magnesium wheels are not practical for production because their cost and corrosion are excessive compared with steel or aluminum alloy wheels. The term *mag wheel*, however, is still heard when referring to alloy (aluminum) wheels.

NOTE: If purchasing replacement aftermarket wheels, check that they are certified by the SFI. SFI is the Specialty Equipment Manufacturers Association (SEMA) Foundation, Incorporated. SEMA and SFI are nongovernment agencies that were formed by the manufacturers themselves to establish standards for safety.

CHROME CLAD WHEELS Chrome clad wheels have become an increasingly popular option on many vehicles. This type of wheel has the following construction features:

- A chrome-plated plastic cladding applied to the front of the wheel.
- The cladding is permanently attached to the aluminum wheel with adhesive foam.
- The foam material is not present near the conical seat area (center) of the wheel.

NOTE: Without the support of the backing foam around the mounting stud holes, it is possible to damage the cladding when mounting the wheel on a balancer. Always follow the vehicle manufacturer's instructions when working with chrome clad wheels.

TIRE VALVES

All tires use a tire valve, called a **Schrader valve**, to hold air in the tire. The Schrader valve was invented in New York in 1844 by August Schrader for the Goodyear Brothers: Charles, Henry, and Nelson. Today, Schrader valves are used not only as valves in tires but on fuel-injection systems, air-conditioning systems, and air shock (ride control) systems. Most tire experts agree that the valve stem (which includes the Schrader valve) should be replaced whenever tires are replaced—tires can last four or more years, and in that time the valve stem can become brittle and crack. A defective or leaking valve stem is a major cause of air loss. Low tire pressure can cause the tire to become overheated. Replacement valve stems are therefore a wise investment whenever purchasing new tires. Aluminum (alloy) wheels often require special metal valve stems that use a rubber washer and are actually bolted to the wheel. ● **SEE FIGURE 108–29.**

NOTE: If the vehicle is equipped with a tire-pressure monitoring system, a nickel tire valve is used. See Chapter 109 for details.

LUG NUTS

Lug nuts are used to hold a wheel to the brake disc, brake drum, or wheel bearing assembly. Most manufacturers use a stud in the brake or bearing assembly with a lug nut to hold the wheel. Some models of VW, Audi, and Mazda use a lug *bolt* that is threaded into a hole in the brake drum or bearing assembly.

NOTE: Some aftermarket manufacturers offer a stud conversion kit to replace the lug bolt with a conventional stud and lug nut.

Typical lug nuts are tapered so that the wheel stud will center the wheel onto the vehicle. Another advantage of the taper of the lug nut and wheel is to provide a suitable surface to prevent the nuts from loosening. The taper, usually 60 degrees, forms a wedge that helps ensure that the lug nut will not loosen. Steel wheels are deformed slightly when the lug nut is torqued down against the wheel mounting flange; be certain that the taper is *toward* the vehicle.

Many alloy wheels use a *shank-nut*-type lug nut that has straight sides without a taper. This style of nut must be used with wheels designed for this nut type. If replacement wheels are used on any vehicle, check with the wheel manufacturer as to the

(b) A metal clamp-type tire valve assembly used on most high-pressure (over 60 PSI) tire applications such as is found on many trucks, RVs, and trailers. The internal Schrader valve threads into the valve itself and can be replaced individually, but most experts recommend replacing the entire valve assembly every time the tires are replaced to help prevent air loss.

proper type and style of lug nut. ● **FIGURE 108–30** shows several of the many styles of lug nuts that are available.

SIZE Lug nuts are sized to the thread size of the stud onto which they screw. The diameter and the number of threads per inch are commonly stated. Since some vehicles use left-hand threads, RH and LH are commonly stated, indicating "right-hand" and "left-hand" threads. A typical size is 7/16-20RH, where the 7/16 indicates the diameter of the wheel stud and 20 indicates that there are 20 threads per inch. Another common fractional size is 1/2 × 20. Metric sizes such as M12 × 1.5 use a different sizing method.

M	metric
12	12 mm diameter of stud
1.5	1.5 mm distance from one thread peak to another

Other commonly used metric lug sizes include M12 × 1.25 and M14 × 1.5 Obviously, metric wheel studs require metric lug nuts.

LUG STUDS Lug studs are usually installed in hubs or drums using a press fit. Serrations on the shoulder of the stud provide support. Most studs are replaceable and should be replaced if the threads are damaged. ● **SEE FIGURES 108–31 AND 108–32**.

FREQUENTLY ASKED QUESTION

What Is a "Knock-Off" Wheel?

A knock-off design wheel is retained to the axle hub using one large retaining nut that has three arms that are used to loosen and tighten them. They are mostly found on older European sports cars and race cars. The wheel is removed by using a lead hammer which has the weight to loosen the nut yet soft enough to not damage the aluminum spokes of the nut. ● **SEE FIGURE 108–33**.

Check the tire information placard, usually located on the driver's door or door jamb, for the specified tire size and inflation pressure.

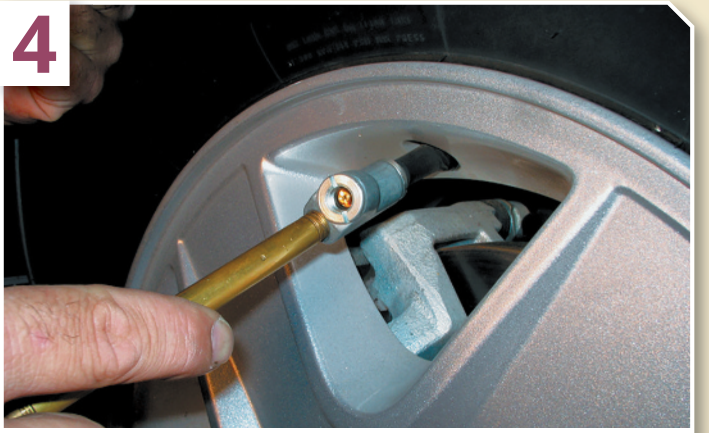
2

Visually check the tires for abnormal wear or damage.

3

Remove the tire valve cap and visually check the condition of the valve stem.

4

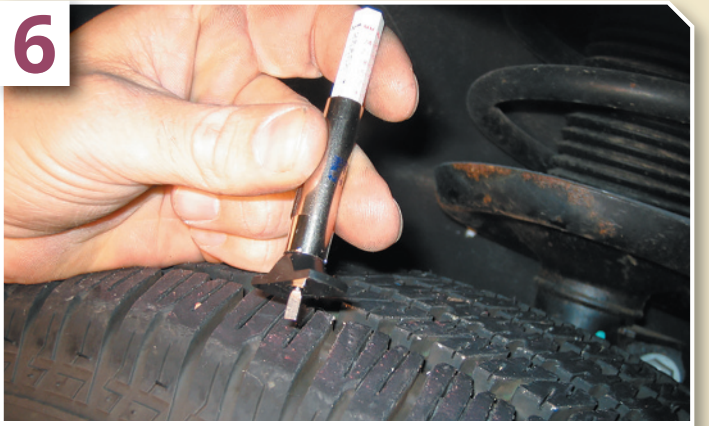


Check inflation pressure by pushing the tire-pressure gauge straight onto the end of the tire valve. If a "hissing" sound is heard, then the reading will not be accurate.

5

Read the pressure and compare to specifications. Use an analog or digital gauge if possible which have been proven to be more accurate than a mechanical pencil-type gauge.

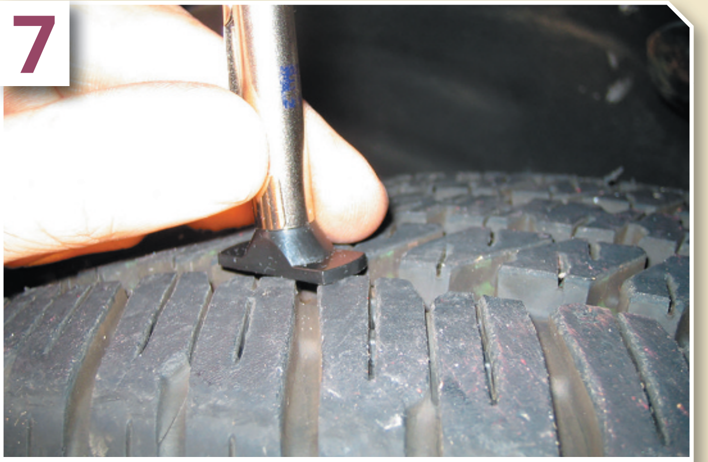
6



A typical tire tread depth gauge.

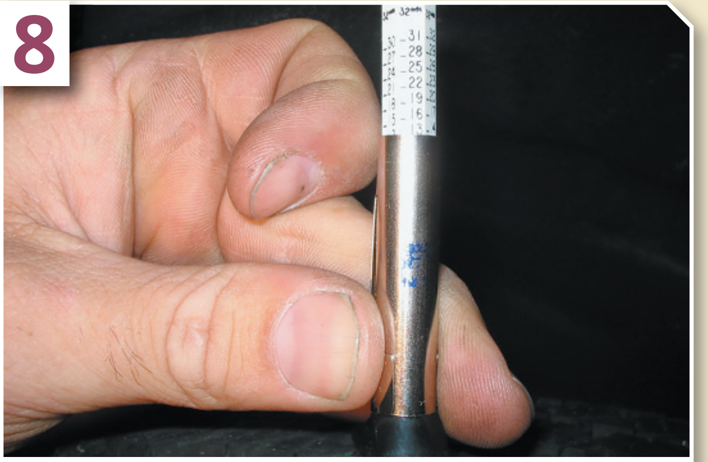
TIRE INSPECTION

7



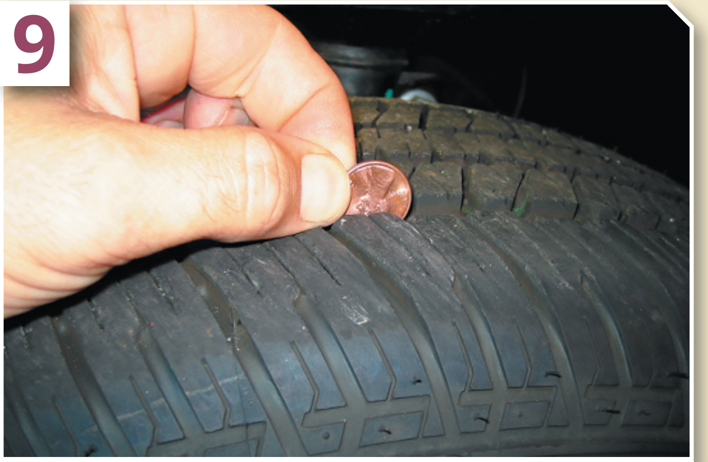
The blade of the tire tread depth gauge is pushed down into the groove of the tire at the lowest part.

8



Remove the gauge from the tire and read the tread depth at the metal housing. Tread depth is usually measured in 1/32's of an inch.

9



If the top of Lincoln's head is visible, then the tread depth is lower than 2/32 inch, which is the legal limit in many states. Most tire experts recommend replacing tires when they reach 4/32 inch instead of 2/32. To check for this depth, use a quarter instead of a penny and look for the top of Washington's head.

TIRE-PRESSURE MONITORING SYSTEMS

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Explain why a tire-pressure monitoring system (TPMS) is used.
- Discuss the TREAD Act.
- Explain indirect TPMS.
- Explain direct TPMS.
- List the two types of TPMS pressure sensors.
- Discuss TPMS sensor operation.
- Discuss the TPMS receiver.
- Explain direct TPMS diagnosis.
- Explain TPMS sensor activations.
- Describe TPMS diagnostic tools.
- List replacement options for TPMS sensors.
- Describe how to relearn TPMS sensors.
- Describe the tools needed to service a TPMS.

NEED FOR TIRE PRESSURE MONITORING

BACKGROUND A **tire-pressure monitoring system (TPMS)** is a system that detects a tire that has low inflation pressure and warns the driver. A tire-pressure monitoring system was first used when run-flat tires were introduced in the 1990s. A driver was often not aware that a tire had gone flat after a puncture. Because a run-flat tire is designed to be driven a limited distance and at limited speed after it loses air pressure, a method of alerting the driver had to be found. There were two systems used:

1. **Indirect**—Commonly used until the 2008 model year and then from 2010 on, there are some vehicles that use the indirect system.
2. **Direct**—A direct-reading pressure system that uses a pressure sensor in each tire is the most commonly used system at this time.

LOW TIRE-PRESSURE EFFECTS Low tire-inflation pressures lead to the following issues:

- Reduces fuel economy due to increased rolling resistance of the tires—3 PSI below specifications results in an increase of 1% in fuel consumption.
- Reduces tire life—3 PSI below specifications results in a decrease of 10% of tire life.
- Increases the number of tire-related faults, which have been estimated to be 90% of all vehicle faults.
- Reduces handling and braking efficiency.
- Hundreds of deaths and thousands of personal injuries are due to problems associated with low tire inflation pressure.

PLACARD COLD INFLATION PRESSURE The term **placard cold inflation pressure** is used in service information to indicate the specified tire inflation pressure. The "placard" is the driver's side door jamb sticker that shows the tire size and the specified tire inflation pressure. It is also normal for a tire to lose one PSI per month just through normal leakage that occurs in any tire. Therefore, it is very important to check and correct inflation pressures regularly. The pressure stated is measured when the tires are cold or at room temperature, which is about 70°F (21°C). ● **SEE FIGURE 109–1**.

TEMPERATURE AND INFLATION PRESSURE The tires become warmer while the vehicle is being driven, so tires should be checked before the vehicle has been driven or allowed to cool after being driven. Tire inflation pressure changes 1 PSI for every 10 degrees. ● **SEE CHART 109–1**.

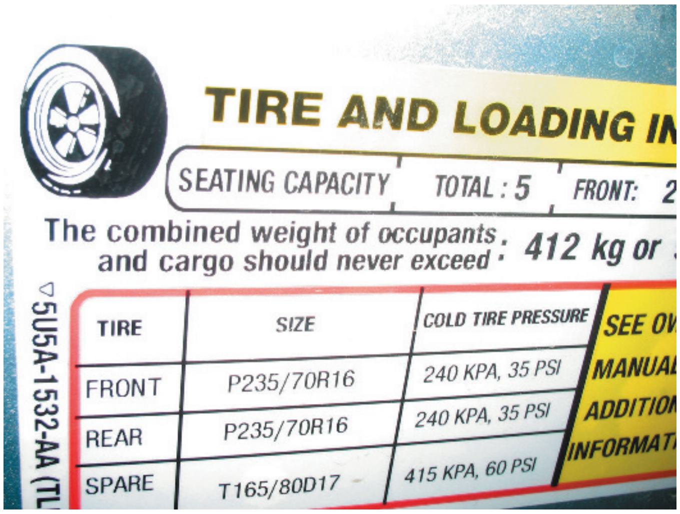

FIGURE 109–1 The tire-pressure placard (sticker) on the driver's side door or door jamb indicates the specified tire pressure.

TECH TIP

Add 2 to 4 PSI

When servicing tires, it is often not practical to allow the time needed for the tires to cool after the vehicle has been driven. To help compensate for the higher pressures due to higher temperature, add 2 to 4 PSI to the cold inflation pressures. ● **SEE FIGURE 109–2**.

TREAD ACT

The **Transportation Recall Enhancement, Accountability, and Documentation (TREAD) Act** requires that all vehicles be equipped with a tire-pressure monitoring system that will warn the driver in the event of an underinflated tire. This act was passed due to many accidents that were caused at least in part to underinflated tires, which resulted in many deaths.

Congress passed the TREAD Act on November 1, 2000. The National Highway Traffic Safety Administration (NHTSA) requires the installation of tire-pressure monitoring systems (TPMSs) in passenger vehicles and light trucks manufactured after September 1, 2007 (2008 model year).

The NHTSA ruling is part one of a two-part final ruling.

- Part one establishes a new Federal Motor Vehicle Safety Standard (FMVSS) 138 that requires tire-pressure monitoring systems be installed in passenger vehicles and light trucks to warn the driver when a tire is 25% below the cold placard pressure.
- Part two includes the requirement to equip vehicles with a tire-pressure monitoring system that was phased-in starting in 2004 with 100% of the vehicles by September 1, 2007 (2008 model-year vehicles).

FMVSS 138 requires all cars, trucks, and vans with a gross vehicle weight rating (GVWR) of 10,000 pounds or less to illuminate a warning lamp within 10 minutes when the inflation pressure drops 25% or more from the vehicle manufacturer's specified cold tire inflation pressure as printed on the door placard.

WARNING LAMP The FMVSS 138 specifies that the driver must be warned of a low tire inflation pressure by turning on an amber warning lamp. The warning lamp must also come on during a bulb check. The spare tire is not required to be monitored, but many vehicle manufacturers do equip full-size spare tires with a pressure sensor.

- If the TPMS warning lamp is on after start-up, the system has detected a tire with low inflation pressure.
- If the TPMS warning lamp is flashing for 60 to 90 seconds, a system fault has been detected.

TWENTY-FIVE PERCENT RULE The TREAD Act specifies that the driver be warned if any tire inflation pressure drops by 25% or more from the placard cold inflation pressure. ● **SEE CHART 109–2**.

INDIRECT TPMS

FUNCTION Indirect TPMSs do not measure the actual tire pressure. Instead, the system uses the wheel speed sensors to detect differences in the speed of the wheels. If a tire is underinflated, the following occurs:

- A tire that is underinflated will have a smaller diameter than a properly inflated tire. ● **SEE FIGURE 109–3**.
- An underinflated tire will rotate faster than a properly inflated tire.

COMPENSATION FOR CORNERING When a vehicle turns a corner, the outside wheels rotate faster than the inside wheels. To compensate for this normal change in wheel rotation speed,

FIGURE 109–2 Inflation pressure increases as the temperature increases. When checking or correcting inflation pressure when the tires are hot, add 2 to 4 PSI to the placard cold inflation pressure. Most experts recommend the use of an electronic tire pressure gauge that is accurate to 0.1 PSI so that all tires can be equally matched and inflated to the specified pressure.

the indirect tire-pressure monitoring system checks the diagonally opposed wheels. ● **SEE FIGURE 109–4**.

If the calculation of the diagonal wheel speed indicates that one of the wheels is rotating faster than the other, the TPMS warning light is illuminated.

DIAGNOSIS OF INDIRECT TPMS The diagnosis of an indirect TPMS system includes the following steps:

STEP 1 Verify the fault.

- If the TPMS warning light is on but not flashing, this indicates that the system has detected a tire with low inflation pressure.

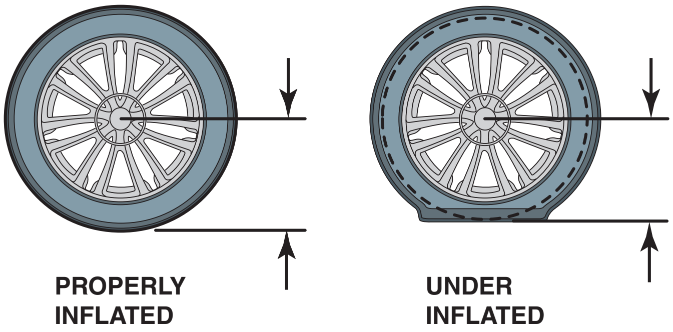

FIGURE 109–3 A tire with low inflation will have a shorter distance (radius) between the center of the wheel and the road and will therefore rotate faster than a tire that is properly inflated.

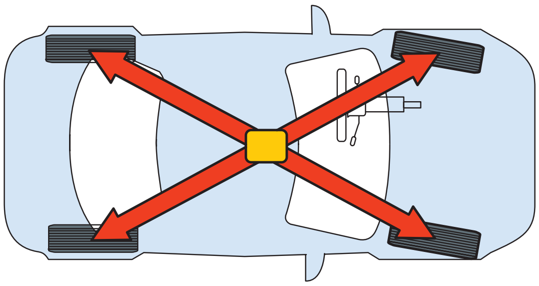

FIGURE 109–4 The speeds of the diagonally opposed wheels are added together and then compared to the other two wheels to check if one tire is rotating faster.

- If the TPMS warning light flashes, this indicates that the system has detected a fault. Check service information for the specified steps to follow.

STEP 2 If the system has detected low tire pressure, check and adjust the tire pressure to that listed on the door pillar

placard or factory specifications as stated in the owner's manual or service information.

STEP 3 Determine and correct the cause of the underinflated tire.

INDIRECT TPMS RELEARN PROCEDURES After checking that all four tires are the same size and condition, the system may require resetting, also called relearn or initialization. Check service information for the exact steps to follow, which could include driving the vehicle over an extended period of time. The procedure usually includes the following steps:

- Inflate all four tires to the placard inflation pressure.
- Depress and hold the reset switch for three seconds. ● **SEE FIGURE 109–5.** The TPMS warning lamp should flash three times.
- Drive the vehicle so the ABS (antilock braking system) controller can learn the new "good" values. Typical driving times include

  Ford—20 minutes of driving
  Toyota—30 to 60 minutes of driving
  General Motors—60 minutes of driving
  Check service information for the exact procedure to follow.

Many service technicians ask the vehicle owner to drive the vehicle instead of taking the technician's time.

DIRECT TPMS

FUNCTION Direct tire-pressure monitoring systems (TPMSs) use individual pressure sensors located in each wheel to measure the inflation pressure.

IDENTIFYING THE SYSTEM All vehicles sold in the United States since the 2008 model year must be equipped with a tire-pressure monitoring system. Often because some vehicles use an indirect system, it is sometimes difficult to determine what type of system is being used by visual inspection only. Therefore, service information is needed to determine what type of system should be on the vehicle before service work is started.

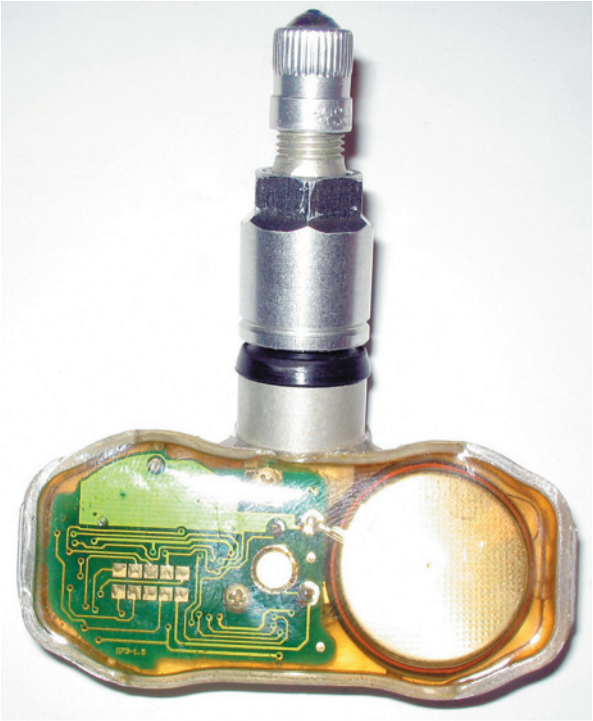

FIGURE 109–6 A clear plastic valve-stem tire-pressure monitoring sensor, showing the round battery on the right and the electronic sensor and transistor circuits on the left.

FREQUENTLY ASKED QUESTION

How Can an Indirect System Meet the TREAD Act Requirements?

Some newer vehicles such as 2009 and newer Audis, plus many models of Honda after 2013 and some Mazda models, use active wheel speed sensors to measure the slight change in vehicle speed compared to the speed in the internal memory of the TPMS module. Always check service information for the exact procedure to follow when a newer vehicle appears to not be equipped with a tire-pressure monitoring system because of no visible signs of a tire pressure sensor.

- Many early (prior to 2008) and some newer vehicles (2010+) use indirect TPMS so there is no visual indication that the vehicle is equipped with a tire-pressure monitoring system.
- If the tire/wheel assembly has a TPMS valve-type sensor, it can usually be identified by the threaded portion of the valve stem. ● **SEE FIGURE 109–6.**

TPMS PRESSURE SENSORS

MANUFACTURERS All direct TPMS sensors transmit tire inflation pressures to a module using a radio frequency (RF) signal. These sensors are manufactured by a variety of manufacturers, including those listed here:

- Beru
- Lear

- Pacific
- Schrader
- Siemens
- TRW

Each sensor uses a 3-volt lithium ion battery that has a service life of 7 to 10 years or 60,000 to 100,000 miles (97,000 to 161,000 km).

TYPES There are two basic types of pressure sensors used in direct pressure-sensing systems.

- **Valve-stem-mounted sensor**—This type of sensor uses the valve stem as the transmitter. The correct (nickel-plated) valve core *must* be used in the aluminum valve stem. If a conventional brass valve is used, moisture in the air will cause corrosion between the two different metals. There are two designs of stem-mounted sensors including
  1. **Snap-in**—This design looks like a rubber valve stem but it uses a tapered brass section and a longer cap. ● **SEE FIGURE 109–7**.

If the cap is short then it does not have a stem-mounted tire pressure sensor. However, the wheel may be equipped with a wheel-mounted (banded) sensor, so care should still be taken to avoid damaging the sensor during service.

  2. **Clamp–in**—This design uses anodized aluminum housing and is held to the wheel using a threaded cap, which must be properly tightened to the specified torque to provide the necessary clamping force. The valve stem itself is the antenna for the sensor. ● **SEE FIGURE 109–8**.

- **Banded sensors**—Banded sensors are installed in the drop well of the wheel and banded or clamped to keep them secure. Early banded sensors, such as those used in Corvettes equipped with run-flat tires, were piezoelectric and did not require a battery. All newer banded sensors include a battery. ● **SEE FIGURE 109–9**.

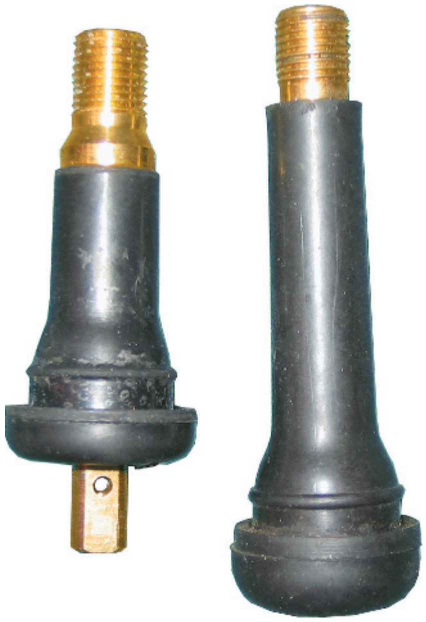

FIGURE 109–7 A conventional valve stem is on the right compared with a rubber TPMS sensor stem on the left. Notice the tapered and larger brass stem. The rubber TPMS sensor also uses a longer cap that makes it easy for a technician to spot that this is not a conventional rubber valve stem.

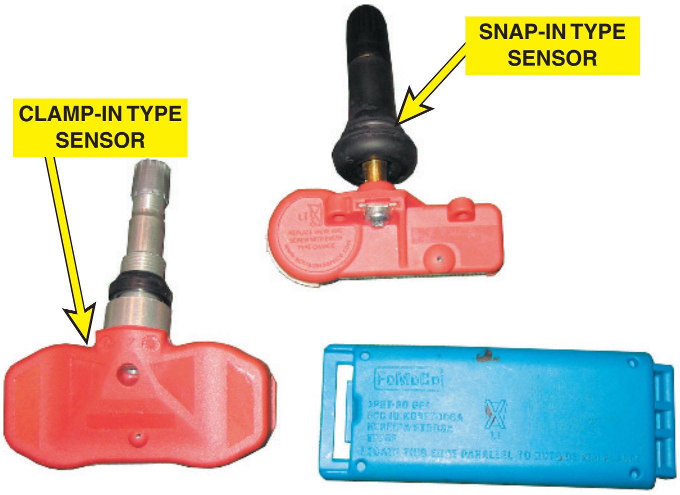

FIGURE 109–9 The three types of TPMS sensors most commonly found include the two stem-mounted rubber (snap-in) and aluminum (clamp-in), left and top, and the banded sensors (right).

MODES OF OPERATION Tire-pressure sensors have three modes of operation:

1. **Active mode**—When the sensor inside detects that the vehicle is traveling above 20 mph (32 km/h), the sensor transmits once every minute.
2. **Sleep mode**—When the vehicle is stopped, the sensor "goes to sleep" to help improve battery life. In this mode, the transmitter still will broadcast tire inflation information every hour or every six hours, depending on the sensor.

3. **Alert mode**—Alert mode is triggered if a rapid change in inflation pressure is detected. In alert (or rapid mode), the tire inflation pressure is sent about every second (every 800 milliseconds on some sensors).

TPMS SENSOR OPERATION

DESIGNS Depending on the type and manufacturer, tire-pressure monitoring sensors can be any of several different designs. The TREAD Act does not specify the type or operation of the pressure sensors, only that the system must be capable of measuring tire inflation pressure and light the TPMS warning lamp. The types of sensors are:

- **Continuous-wave-type sensor**—Designed to signal a tester when exposed to five to seven seconds of continuous 125 kHz wave signal.
- **Magnetically triggered-type sensor**—Designed to trigger a tester if exposed to a powerful magnetic force.
- **Pulse-width-modulated-type sensor**—Designed to be triggered when exposed to modulated wave 125 kHz signal.

The sensor can also vary according to the frequency at which it transmits tire-pressure information to the receiver in the vehicle. The two most commonly used frequencies are:

- 315 kHz
- 433.92 MHz (commonly listed as 434 MHz)

TPMS RECEIVER

LOCATIONS The wireless TPMS receiver is housed in one of the following locations, depending on the vehicle:

- Remote keyless entry (RKE) receiver
- Body control module (BCM)
- Door module
- Individual antennas near each wheel well. These individual antennas then transmit tire-pressure information to the driver information center. ● **SEE FIGURES 109–10 AND 109–11**.

FREQUENTLY ASKED QUESTION

Does a TPMS Sensor Work before Being Installed?

No. New tire-pressure warning sensors (transmitters) are shipped in **storage mode**. This mode prevents the battery from becoming discharged while in storage. When the transmitter is installed in a wheel/tire assembly and the tire is inflated to more than 14 PSI (97 kPa), the transmitter automatically cancels storage mode. Once a transmitter has canceled storage mode, it cannot enter this mode again. Therefore, once a sensor has been installed and the tire inflated above 14 PSI, the clock is ticking on battery life.

CASE STUDY

The TPMS Warning Lamp

The owner of a six-year-old Honda Civic was concerned that the tire-pressure warning lamp was on even though all of the tires had the proper inflation pressure. The technician noted that the TPMS warning lamp was not the one that indicates a low tire, but it was the one that indicates that a fault with the system has been detected. ● **SEE FIGURE 109–12**.

The technician used a factory-level aftermarket scan tool and retrieved several diagnostic trouble codes for "pressure sensor signal failures." ● **SEE FIGURE 109–13**.

The technician also noted that the tires were relatively new and recommended to the owner that all four TPMS sensors be replaced. The major reason why the technician recommended that all of them be replaced is that the battery life is normally 7 to 10 years so the life of the sensors is near the end of their useful life. Also, the technician thought that one or more of the sensors may have been damaged when the new tires were replaced. The vehicle owner approved the replacement of the sensors and the system was restored to normal operation.

Summary:

Complaint—TPMS warning lamp was on.
Cause—Most of the tire-pressure warning system sensors had a stored diagnostic trouble code.
Correction—All four tire-pressure sensors were replaced and the system relearned to the new sensors. The codes were cleared and the system was restored to normal operation.

TECH TIP

Check the TPMS Sensors before and after Service

It is wise to check that all of the TPMS sensors are working before beginning service work. This is commonly called "test before you touch." For example, if the tires need to be rotated, the sensors will have to be reprogrammed for their new location. If a tire-pressure monitoring sensor is defective, the procedure cannot be performed. Use an aftermarket or original equipment tire-pressure monitoring sensor tester to check that the sensors respond. ● **SEE FIGURE 109–14**.

Then the tire-pressure sensors should be checked again after the service to make sure that they are working correctly before returning the vehicle to the customer.

TPMS DIAGNOSIS

WARNING LIGHT ON If the TPMS warning light is on and not flashing, the system has detected a tire that has low inflation pressure. ● **SEE FIGURE 109–15**.

If the TPMS light is on, perform the following steps:

STEP 1 Check the door placard for the specified tire inflation pressure.

STEP 2 Check all tires using a known-accurate tire-pressure gauge.

STEP 3 Inflate all tires to the specified pressure.

NOTE: Some systems will trigger the TPMS warning light if a tire is overinflated. An overinflated tire is also a safety-related problem.

WARNING LIGHT FLASHING If the TPMS warning lamp is flashing on and off or if a separate TPMS system warning light is on, the system has detected a fault. Faults could include the following issues:

- Defective wheel sensors, such as a sensor with a dead battery.
- A fault in the receiver, such as in the remote keyless entry module.

TECH TIP

Check the Spare

Many vehicles equipped with a full-size spare tire also have a TPMS sensor. If the inflation pressure decreases enough, the system will trigger the TPMS warning light. This is confusing to many vehicle owners who have checked all four tires and found them to be properly inflated. This fault often occurs during cold weather when the tire inflation pressure drops due to the temperature change. Most 2008 and newer vehicles with a full-size spare tire will come equipped with a TPMS sensor in the spare.

Check service information for the exact procedure to follow if the TPMS warning lamp is flashing. Always follow the specified diagnostic and service procedures.

CAUTION: Stop leak should never be used in a tire that is equipped with the TPMS sensor because the sensor can be damaged.

TPMS SENSOR ACTIVATIONS

ACTIVATING THE SENSOR A tire-pressure monitoring system (TPMS) sensor needs to be activated to verify that the sensor actually works. This should be performed before any tire or wheel service is performed. There are three methods used to activate a TPMS sensor to cause it to send a signal that can be captured to verify proper operation. These activation methods include those listed here:

1. Using a magnet (aluminum wheels and stem-mounted sensors only). ● **SEE FIGURE 109–16**.
2. Changing inflation pressure (usually requires lowering the inflation pressure by 5 to 10 PSI). This method is called the **delta pressure method**. The term *delta* refers to a change and is named for the Greek letter delta (Δ).
3. Triggered by a handheld TPMS tester that transmits a signal to wake up the sensor.

There are two formats used, depending on the sensor. They include the following:

- 125 kHz constant or continuous pulse
- 125 kHz pulse-width-modulated pulse

TPMS DIAGNOSTIC TOOLS

SCAN TOOLS Scan tools can be used for TPMS service if the scan tool is an original equipment tool for the vehicle make or if an aftermarket scan tool has original equipment compatible

CASE STUDY

The Acura Dash Display Problem

The tires were rotated on an Acura equipped with a direct-type TPMS. The published relearn procedure included driving the vehicle above 15 MPH for at least 40 seconds. However, even after driving for over 10 miles, the pressures were not being displayed on the instrument panel cluster (IPC). The technician thought that maybe there was fault with the IPC. The owner decided to think it over what to do and drove the vehicle home. The next day, when the vehicle was driven, the tire pressure display worked as designed. Apparently the system needed to be powered down and allowed to go to sleep before it would start to transmit the new locations to the IPC.

Summary:

Complaint—The tire pressures for each wheel were not being displayed on the dash after the tires were rotated.
Cause—The TPMS apparently needed to go to sleep and then awaken before the tire pressure would be displayed on the dash.
Correction—No action was required by the service technician because the system started to transmit after going to sleep, and the display operated as designed.

software to access the chassis or body functions of the vehicle. A scan tool is used to perform the following functions:

1. **Register TPMS sensors**—A replacement TPMS transmitter has an eight-digit number, called the **transmitter ID**, on each valve/transmitter assembly. ● **SEE FIGURE 109–17**.
2. **Perform initialization**—This step assigns a transmitter ID to the correct position on the vehicle, such as right front (RF).
3. **Monitor sensor values**—TPMS transmitters send information to the controller on the following operations:
    - Sensor identification
    - Tire inflation pressure
    - Tire air temperature (some sensors)
    - Sensor battery voltage (some sensors)

HANDHELD TESTERS Several manufacturers produce handheld testers to reset the sensors. These tools are used to perform the following functions:

- TPMS sensor activation
- TPMS sensor relearn
- To program a new TPMS sensor

Tools are available from the following companies:

- OTC (**http://www.otctools.com**)
- Bartec (**http://www.bartecusa.com**)
- Snap-on (**http://www.snapon.com**)

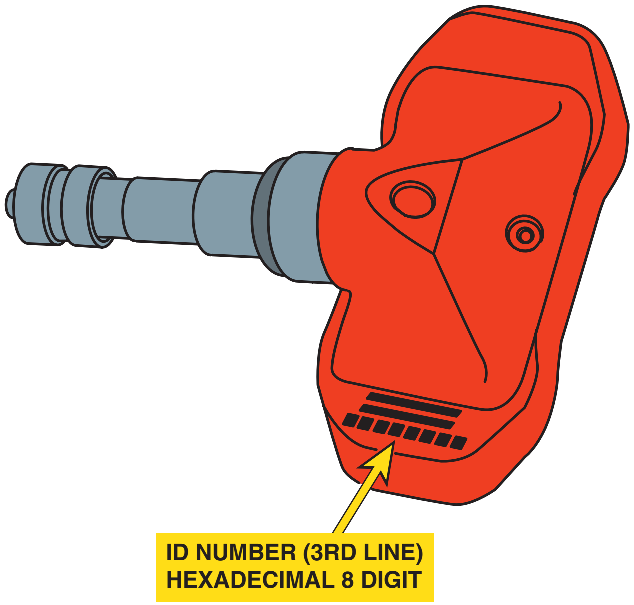

FIGURE 109–17 When replacing a TPMS sensor, be sure to record the sensor ID because this needs to be entered into the system through the use of a tester or scan tool.

SENSOR REPLACEMENT OPTIONS

ORIGINAL EQUIPMENT-BASED SENSORS These sensors are made by the original equipment (OE) manufacturer and usually are direct replacement for the factory unit.

- They are electronically identical to the original sensor.
- The relearn procedure is the same.
- May be a different color.

These sensors are usually tested and validated according to OE specifications, but one part number may cover many factory part numbers.

AFTERMARKET SENSORS There are many aftermarket TPMS sensors and these can be divided into several groups including:

- OE-based replacement
- Multiple protocol sensors that can be programmed to match whatever the vehicle needs
- Fully programmable sensor—also called *clones.* This type needs a separate programming device.

If using aftermarket tire-pressure monitoring system pressure sensors, always check and follow the instructions that came with the sensors to properly program the vehicle being serviced.

TPMS SENSOR RELEARN

TERMS USED Service information should always be checked when performing a relearn procedure. The relearn procedure may be called any of the following terms:

- Calibrate
- Recalibration

- Initialization
- Reprogramming
- Relearn
- Training

CATEGORIES Most relearn procedures fall into four categories:

1. **Auto relearn**—Install sensors, drive the vehicle for a prescribed amount of time and rate of speed. The vehicles that often can be automatically relearned usually include:
    - Chrysler
    - Dodge
    - Ram
    - Jeep
    - Jaguar
    - Land Rover
2. **European relearn**—Install sensors, put the vehicle in reset mode through the driver information center (DIC), and drive the vehicle for a prescribed amount of time and rate of speed. Used on many European brands including those listed here:
    - VW
    - Audi
    - Mercedes Benz
    - BMW
3. **Manual relearn**—Enter the vehicle into learn mode by following the instructions found in the owner's manual, trigger all four sensors with an activation tool or scan tool. Used on many domestic vehicles including the following brands:
    - Chevrolet
    - Buick
    - GMC
    - Ford
    - Lincoln
4. **OBD relearn**—Scan all four sensors with a scan tool, input the electronic serial number (ESN), and download the ESN into the TPMS ECU. Required on many Japanese brands including the brands listed here:
    - Toyota
    - Lexus
    - Nissan
    - Infiniti
    - Subaru
    - Honda

Always check service information for the exact procedures to follow on the vehicle being serviced.

FREQUENTLY ASKED QUESTION

How Does a Vehicle Learn Where the Sensor Is Located?

Vehicles that are capable of automatically learning their new position after a tire rotation or after being replaced can detect their location by the following procedures:

- Some vehicles use an initiator located in each wheel well. The TPMS sensor broadcasts the pressure information which is detected by each initiator and then transmitted over a bus network to the TPMS or body control module. The module then will know where the sensor is located by its unique serial number.
- An accelerometer in the sensor allows the sensor to "know" which side of the vehicle the sensor is located. When a tire revolves, it turns in an opposite direction than a wheel on the opposite side of the vehicle. By using the accelerometer, the TPMS controller can detect which side the sensor is located.
- Then the TPMS module checks for the relative strength of the signal being transmitted by the sensor. If the receiver is located at the rear of the vehicle, and two sensors are showing stronger signal, then these two must be the two rear wheels.

GENERAL MOTORS EXAMPLE The following procedure will allow the service technician to reprogram the TPMS after tire rotation on a General Motors vehicle without using a scan tool:

STEP 1 With KOEO (key on, engine off), the "lock" and "unlock" buttons on the key fob should be simultaneously pressed and held. The horn will chirp within 10 seconds, indicating the receiver is in programming mode. The programming procedure must now be completed within five minutes, with no more than one minute between programming.

NOTE: If the horn does not chirp at the start of this procedure, the TPMS option has not been enabled. A scan tool is needed to enable the system.

STEP 2 At the left front wheel, the special magnet tool must be held over the valve stem to force the sensor to transmit its code. The horn will chirp once, indicating the system has recognized the sensor. The next sensor must be programmed within one minute.

STEP 3 The remaining sensors should be programmed in the following order: RF, RR, LR. The horn will chirp once when each sensor has been detected. It will chirp twice to indicate completion of the programming process. ● **SEE FIGURE 109–18**.

TECH TIP

All Sensors Will Fail

All TPMS pressure sensors will fail because they contain a battery that has a service life of 7 to 10 years. What does this mean to the service technician? This means that if new tires are being installed on a five or six-year-old vehicle equipped with tire-pressure sensors, then the customer should be notified that the TPMS sensors could fail almost anytime.

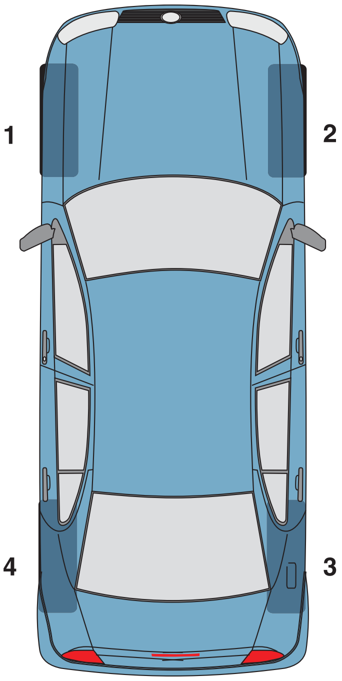

FIGURE 109–18 The sensor relearn procedure is performed in the following order after the system has been placed in learn mode: LF, RF, RR, and then LR.

FREQUENTLY ASKED QUESTION

Can TPMS Sensors Be Switched to New Wheels?

Maybe. It depends on the style of the new or replacement wheels as to whether the sensors will fit or not. Some vehicles are designed to allow for a second set of sensors such as for winter tires. Many Lexus vehicles can be programmed to use set #1 or set #2. It is best to check before purchasing new wheels. Another set of TPMS sensors could be a major added expense.

TPMS SENSOR SERVICE TOOLS

ITEMS NEEDED Whenever servicing a tire/wheel assembly that has a direct TPMS system, certain items are needed:

1. **Information**—Check service information for the exact procedures to follow for the vehicle being serviced. Vehicles and sensors are different for different vehicles.
2. **Digital tire-pressure gauge**—Many mechanical tire-pressure gauges are not accurate. An old mechanical gauge may be used to ensure that all tires are inflated to the same pressure, but the pressure may not be accurate. ● **SEE FIGURE 109–19**.
3. **Tire valve core torque wrench**—This calibrated tool ensures that the valve core is tightened enough to prevent air loss, but not too tight to cause harm. The recommended torque is 3 to 5 inch-pounds (0.34 to 0.56 N-m [Newton meters]). ● **SEE FIGURE 109–20**.
4. **Tire valve nut torque wrench**—Most are 11 or 12 mm in size and the torque ranges from 30 to 90 inch-pounds (4 to 10 N-m).
5. **Sensor service kit**—If a pressure sensor is going to be reused, the following service parts must be replaced:
   - Cap
   - Valve core (nickel-plated only)
   - Nut
   - Grommet

These parts are usually available individually or in an assortment package. Pressure sensor and kit information can be found at the following websites:

- **http://www.rubber-inc.com**

● **SEE FIGURES 109–21 AND 109–22**.

REVIEW QUESTIONS

1. How does the use of wheel speed sensors detect a tire with low inflation pressure?
2. What is the difference between faults when the TPMS warning lamp is on compared with when it is flashing?
3. What is the difference between indirect and direct tire-pressure monitoring system?
4. TPMS pressure sensors can be made by what manufacturer?
5. What are the three modes of sensor operation?

CHAPTER QUIZ

1. What is the purpose of the TPMS system?
   - **a.** To detect a tire that has low inflation pressure
   - **b.** To inflate a low tire if needed
   - **c.** To flash a warning light if a tire with low inflation pressure is detected
   - **d.** All of the above
2. Technician A says that tire pressure will drop 1 PSI for every 10 degrees drop in temperature. Technician B says that the two type of TPMS pressure sensors are snap-in and clamp-in. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
3. The FMVSS 136 law (TREAD Act) requires that the driver be notified if the tire inflation pressure drops how much?
   - **a.** 30%
   - **b.** 25%
   - **c.** 20%
   - **d.** 15%
4. Two technicians are discussing the indirect tire-pressure monitoring system. Technician A says that it was used by some vehicle manufacturers. Technician B says that it uses the speeds of the RF and LR tires and compares the rotating speeds of the LF and RR tires to detect a low tire. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
5. What mode does a direct pressure sensor enter when the vehicle is stopped?
   - **a.** Sleep mode
   - **b.** Storage mode
   - **c.** Alert mode
   - **d.** Active mode

6. What tools and supplies are needed to service TPMS?
   - **a.** Tire pressure gauge
   - **b.** Tire valve core torque wrench
   - **c.** Sensor service kit
   - **d.** All of the above
7. The tire pressure sensor sends a signal to the ____________.
   - **a.** door module
   - **b.** RKE receiver
   - **c.** BCM
   - **d.** Any of the above, depending on the vehicle
8. What does the "delta pressure method" mean?
   - **a.** Change the inflation pressure
   - **b.** Activate the sensor so it broadcasts the pressure to the scan tool
   - **c.** Inflate the tire to the specified pressure
   - **d.** Use a handheld tester to read the pressure as reported by the sensor
9. When a TPMS sensor needs replacement, which of the following is *not* an option?
   - **a.** Replace with an OE sensor
   - **b.** Replace with a programmable aftermarket sensor
   - **c.** Replace the sensor battery and program it to the vehicle
   - **d.** Replace with a multiple protocol sensor
10. To activate or learn a direct pressure sensor, what does the service technician need to do?
   - **a.** Enter learn mode and use a magnet.
   - **b.** Enter learn mode and decrease inflation pressure.
   - **c.** Use a handheld tester.
   - **d.** Any of the above depending on the vehicle and system.

TIRE AND WHEEL SERVICE

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- State the importance of proper tire inflation.
- Discuss nitrogen inflation.
- Describe tire inspection.
- Describe the correct sequence for lug nut removal, tightening procedure, and torque for wheel installation.
- State the purpose of tire rotation.
- Discuss radial runout.
- Discuss lateral runout.
- List the steps for replacing a tire.
- Discuss tire balancing.
- Discuss wheel weights.
- Discuss wheel/tire balancers.
- Discuss how to repair tires using internal patch.

KEY TERMS:

Lateral runout 1329 • Match mounting 1332 • Modified X 1328 • Radial force variation (RFV) 1329 • Radial runout 1329 • Shimmy 1329 • Tire rotation 1327 • Tramp 1329

TIRE SERVICE AND PROPER INFLATION

NEED FOR SERVICE Proper tire service is extremely important for the safe operation of any vehicle. Premature wear can often be avoided by checking and performing routine service, such as frequent rotation and monthly inflation checks. Avoid overloading the vehicle and have any leaks repaired as soon as possible. ● **SEE FIGURE 110–1**.

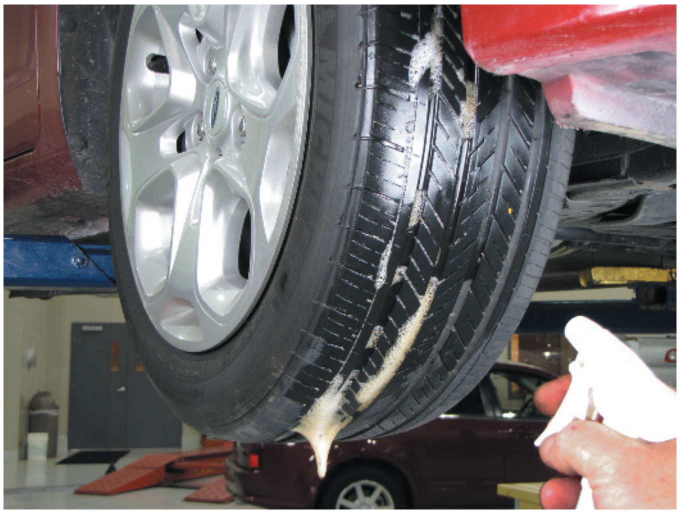

FIGURE 110–1 Using soapy water from a spray bottle is an easy method to find the location of an air leak from a tire.

TIRE INFLATION PRESSURE Tires should always be inflated to the pressure indicated on the driver's door or pillar sticker. Tires should be checked when cold, before the vehicle has been driven, because driving on tires increases the temperature and therefore the pressure of the tires. Proper tire inflation is important for the following reasons:

- **Inflation pressure carries the load of the vehicle.** If the pressure is low, the load capacity of the tire is decreased. ● **SEE FIGURE 110–2**.
- **Inflation pressure varies with temperature.** Tires lose 1 PSI for every 10 degree drop in temperature. This means that as the temperatures and seasons change, so does the inflation pressure inside the tires. For example, if tires were inflated to 35 PSI on the first day of summer (June 21) when the temperature was 90°F (32°C) then the following pressures would occur, assuming no air loss at all:
  - Summer (June 21) 90°F—35 PSI
  - Fall (September 21) 70°F—33 PSI

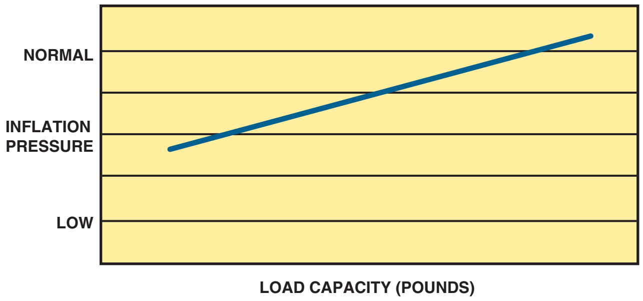

FIGURE 110–2 Chart showing the relationship between tire inflation pressure and load capacity of the tire.

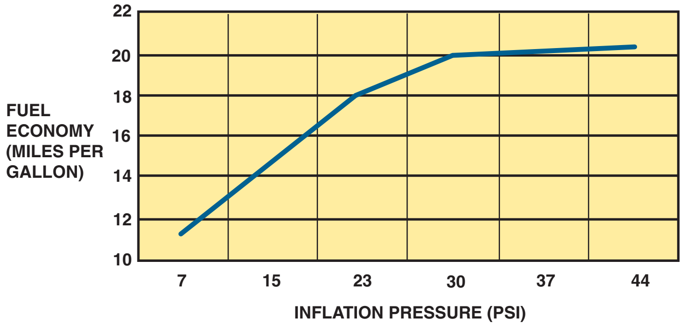

FIGURE 110–3 Note that a drop in inflation pressure has a major effect on fuel economy.

- Winter (December 21) 30°F—29 PSI
- Spring (March 21) 60°F—32 PSI

Also, it is normal for a tire to lose 1 PSI per month just through normal leakage that occurs in any tire. Therefore, it is very important to check and correct inflation pressures regularly.

- **Tire inflation affects fuel economy.** A drop in inflation pressure from 30 to 23 PSI can result in a drop of fuel economy from 20 miles per gallon to 18 miles per gallon. ● **SEE FIGURE 110–3**.
- **Tire inflation affects tire life.** Even a slight drop in air pressure can have a major effect on the life of a tire. If, for example, the inflation pressure dropped 10 PSI, the life of the tire would be reduced by 40%. ● **SEE FIGURE 110–4**.
- **The TREAD Act specifies** that the driver be notified if the inflation of a tire drops by 25%. However, 25% represents a loss of air pressure of about 8 PSI. A drop of 8 PSI means an approximate 2 mpg (miles per gallon) decrease in fuel economy as well as about a 25% reduction in tread wear.

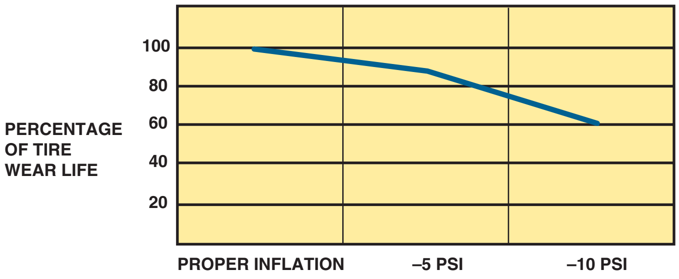

FIGURE 110–4 Note that if a tire is underinflated by 5 PSI, the life expectancy is reduced by 20% and by about 40% if the inflation pressure is less than specified by 10 PSI.

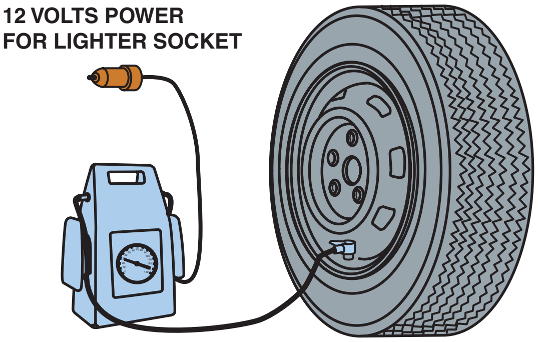

12 VOLTS POWER FOR LIGHTER SOCKET

FIGURE 110–5 A temporary inflation pump that uses 12 volts from the cigarette lighter to inflate the tire.

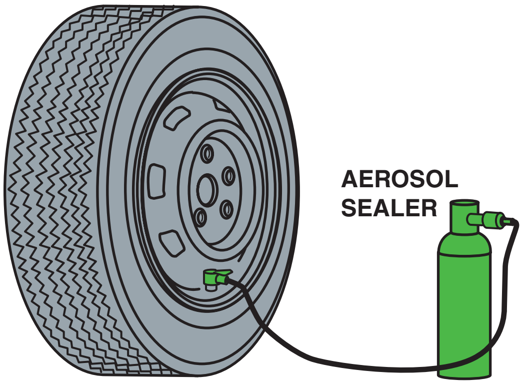

FIGURE 110–6 Many vehicle manufacturers include an aerosol can of sealer on vehicles that are not equipped with a conventional spare tire.

FREQUENTLY ASKED QUESTION

What Is a "Temporary Mobility Kit"?

A temporary mobility kit is a system to inflate a flat tire supplied by the vehicle manufacturer instead of a spare tire. A temporary mobility kit can include

- An electric compressor powered by the cigarette lighter and a can of stop leak. ● **SEE FIGURE 110–5**.
- An aerosol spray can that provides inflation and sealer. ● **SEE FIGURE 110–6**.

Either type can be found in many vehicles because such devices save weight, increase trunk space, and cost less than a conventional spare tire and jack. However, these kits are designed to be a temporary repair only because the cause of the low tire was never determined. If the tire appears to be fixed, many vehicle owners may think that the tire has been repaired. However, the tire should be carefully inspected inside and out for damage and properly repaired.

NITROGEN INFLATION

DEFINITION Air contains about 78% nitrogen, 21% oxygen, and 1% other gases. When tires are inflated using air, oxygen as well as some moisture is included. Some shops recommend and inflate tires using nitrogen instead of using compressed air.

REASONS TO USE NITROGEN The reasons include

- The nitrogen molecule is slightly larger than the oxygen molecule so the tire will lose pressure faster if air is used instead of nitrogen.

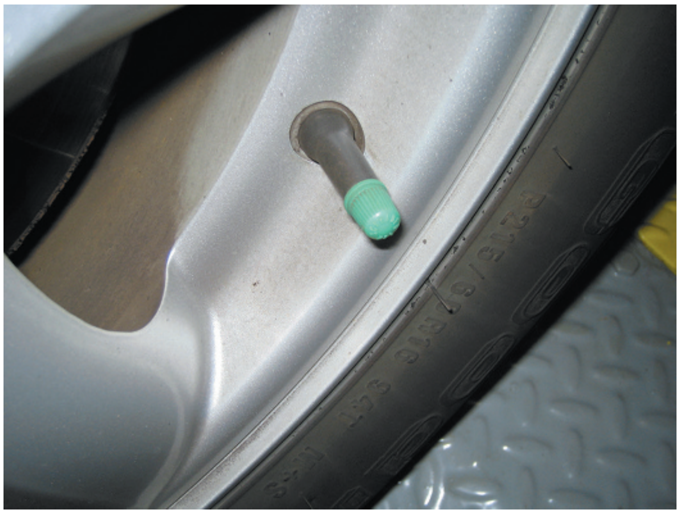

FIGURE 110–7 Most shops that use nitrogen inflation install a green tire valve cap to let others know that nitrogen, rather than air, has been used to inflate the tire.

- Compressed nitrogen contains less moisture than compressed air. When the tire heats up, moisture in the tire vaporizes and expands, causing the pressure inside the tire to increase. Even small changes in tire pressure can noticeably affect the handling of the vehicle.
- Race teams use nitrogen because they come to the track with a cylinder of nitrogen to power the air tools.
- Race teams also have more control over how much the pressure will increase when the tires heat up, because nitrogen is less likely to change pressure with temperature change.
- Some oxygen in the tires could, over a long period of time, cause the oxidation of the inner liner of the tire and the corrosion of the wheel.
- Many shops use green valve caps when they fill the tires with nitrogen. ● **SEE FIGURE 110–7**.

TECH TIP

Fine-Tune Handling with Tire-Pressure Changes

The handling of a vehicle can be changed by changing tire pressures between the front and rear tires.

- **Understeer—**A term used to describe how a vehicle handles when cornering where additional steering input is needed to maintain the corner, or resisting turning into a corner. This is normal handling for most vehicles.
- **Oversteer—**A term used to describe handling where correction while cornering is often necessary because the rear tires lose traction before the front tires.

Tire Pressure	To Decrease Understeer	To Decrease Oversteer
Front tire inflation pressure	Increase	Decrease
Rear tire inflation pressure	Decrease	Increase

CAUTION: Do not exceed the maximum inflation pressure as imprinted on the tire sidewall.

FREQUENTLY ASKED QUESTION

What Is the Color Band on a Valve Core?

The red band cores have a seal temperature range of 130 to 250°F (54 to 121°C), and are mainly for use in trucks or high-performance applications. The valve cores with a black band are rated for 107 to 225°F (54 to 107°C). Brass tire valve cores are for standard rubber stems, whereas nickel plated cores are for TPMS sensors to prevent corrosion.

TIRE INSPECTION

VISUAL INSPECTION All tires should be carefully inspected for faults in the tire itself or for signs that something may be wrong with the steering or suspension systems of the vehicle. Check all tires for the following signs:

- Excessive wear. ● **SEE FIGURE 110–8**.
- Sidewall faults. ● **SEE FIGURE 110–9**.

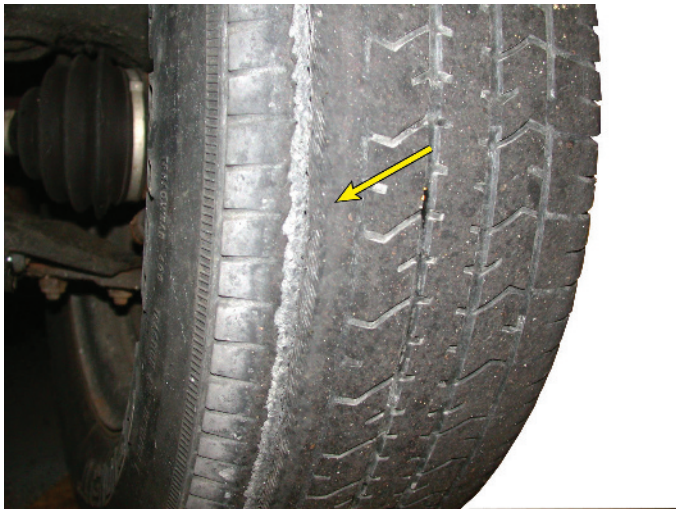

FIGURE 110–8 Excessively worn tire showing the belt material on the inside edge. This tire requires replacement.

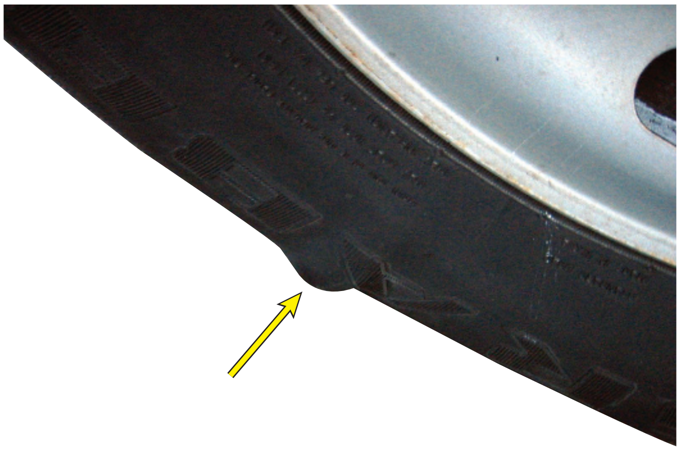

FIGURE 110–9 A bulge in a tire as a result of either an injury to the sidewall, such as contact with a curb, or an internal fault in the tire. This tire requires replacement.

- Underinflation, which shows as wear on both the inside and outside edges of the tread.
- Overinflation, which shows as excessive wear in the center of the tread.
- Wear on the inner or outer part of the tire only which usually indicates alignment problem. ● **SEE FIGURE 110–10**.

TREAD DEPTH Tread depth should always be measured when inspecting tires and the results recorded in the work order. Typical tread depth and what they mean are as follows:

- New tires = 9/32-11/32 (7–9 mm)
- 6/32 inch (5 mm) or more—No need to replace the tire
- 4/32 to 5/32 inch (3 to 4 mm) Consider replacement
- 2/32 inch (2 mm) or less Replace (2/32 in. is the legal limit) ● **SEE FIGURE 110–11**.

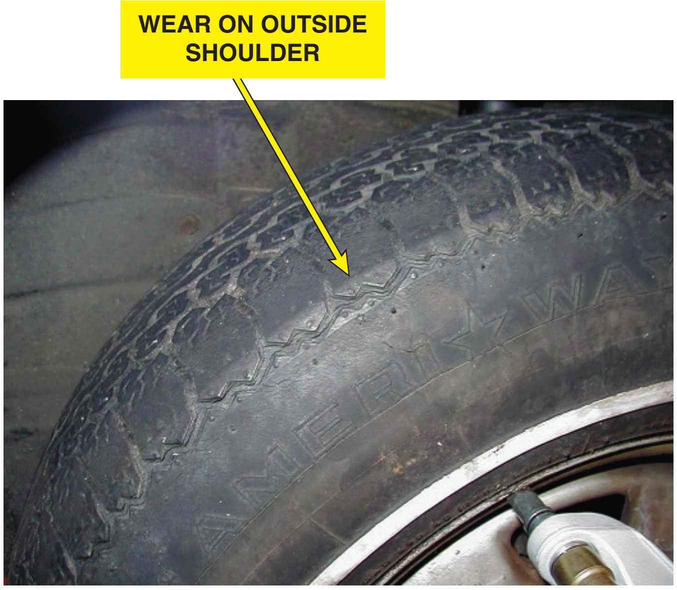

FIGURE 110–10 Wear on the outside shoulder only is an indication of an alignment problem.

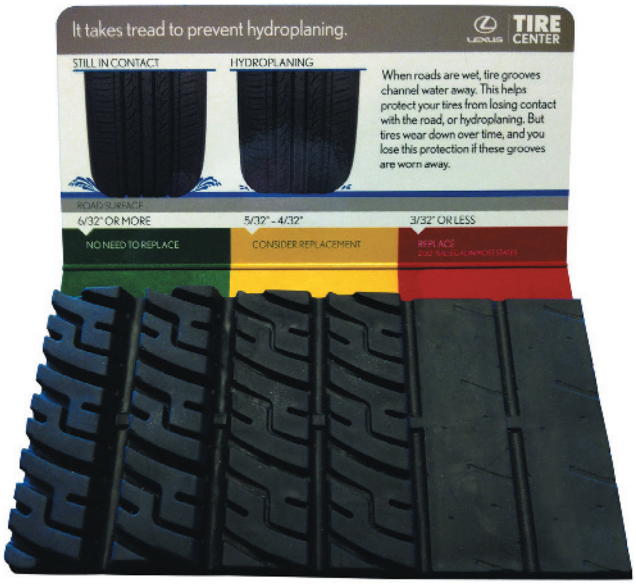

When roads are wet, tire grooves channel water away. This helps protect your tires from losing contact with the road, or hydroplaning. But tires wear down over time, and you lose this protection if these grooves are worn away.

FIGURE 110–11 A display at a Lexus dealer used to show customers a visual representation of what a tire looks like at various tread depth amounts. This display helps vehicle owners understand tire tread depth measurements.

TECH TIP

Stop and Inform the Customer

If a lug nut is hard to turn when removing a wheel, stop. Inform the customer before proceeding because there may be an issue with damaged or corroded wheel studs. If a wheel stud breaks, the service technician is often blamed and the shop may be responsible for the repair. By informing the customer, this issue is fully documented and the customer will have a say whether or not to proceed with the wheel service.

WHEEL REMOVAL/ INSTALLATION

LUG NUTS When removing lug nuts, notice the amount of force needed to remove the nuts. If a wrench or impact wrench is needed to unscrew the nuts, the threads are damaged and should be repaired or the stud replaced. Always start wheel lug nuts by hand. Be certain that all wheel nut threads have been engaged at least three threads before tightening the nut with a wrench or impact.

LUG NUT TORQUE For wheel mounting torque, make certain that the wheel studs are clean and dry, and torqued to the manufacturer's specifications.

CAUTION: Most manufacturers warn that the wheel studs should not be oiled or lubricated with grease; this can cause the wheel lug nuts to loosen while driving. Always follow the vehicle manufacturer's recommended service procedures.

TIGHTENING SEQUENCE Always tighten lug nuts gradually in the proper sequence—star pattern (tighten one nut, skip one, and tighten the next nut). This helps prevent warping the brake drums or rotors, or bending a wheel. ● **SEE FIGURE 110–12**.

Many factory-installed and aftermarket wheels use anti-theft wheel lug nuts, usually on only one wheel stud. When removing or installing a locked lug nut, be sure the key is held square to the lug nut to prevent damaging either the nut or the key. ● **SEE FIGURE 110–13**.

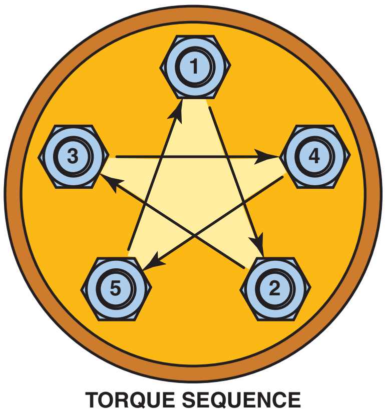

FIGURE 110–12 Always tighten wheel lug nuts (or studs) in a star pattern to ensure even pressure on the axle flange, brake rotors or drums, and the wheel itself.

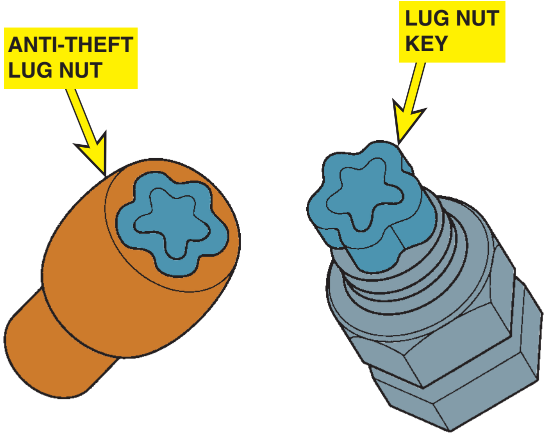

FIGURE 110–13 Most manufacturers recommend using hand tools rather than an air impact wrench to remove and install lock-type lug nuts to prevent damage. If either the key or the nut is damaged, the nut may be very difficult to remove.

TIGHTENING TORQUE All vehicle manufacturers recommend that the lug nuts be tightened to factory specifications using a *torque wrench*. To properly use a torque wrench to tighten wheel lug nuts, perform the following steps:

STEP 1 Check service information for the specified torque for the lug nuts on the vehicle being serviced. For most passenger vehicles, this torque is usually 80 to 100 lb-ft.

STEP 2 With the vehicle raised to a good working height, place the wheel/tire assembly over the lug studs.

STEP 3 Start all lug nuts by hand at least three threads to help assure that the threads are not damaged or cross threaded which can affect the tightening torque.

STEP 4 Snug the lug nuts in a star pattern using a ratchet and socket or a battery-powered impact set to a light torque. Snug the lug nuts in a star pattern (snug one, skip one, then snug another). This method helps insure that the wheel is installed straight onto the hub.

STEP 5 Lower the vehicle to the ground.

STEP 6 Set the torque wrench to the specified torque. This is usually achieved on a "clicker" type torque wrench by twisting the end of the handle until the specified torque setting is reached and then the lock is set to prevent it from changing.

STEP 7 Using the torque wrench with the correct socket, slowly and gently tighten the lug nuts. Do not jerk or move the torque wrench rapidly as this will affect the torque applied to the lug nuts. The torque wrench will click when the wrench reaches the preset to tightening torque. When the click occurs, release the force on the torque wrench. Another click will be heard when the torque is relieved. ● **SEE FIGURE 110–14**.

STEP 8 Double-check that all lug nuts are correctly tightened.

STEP 9 When finished, set the torque setting on the torque wrench to its lowest setting to keep pressure off the internal spring when it is stored. This helps prevent inaccurate torque readings the next time it is used.

Whenever you install brand-new aluminum wheels, retorque the wheels after the first 25 miles. The soft aluminum often compresses slightly, loosening the torque on the wheels.

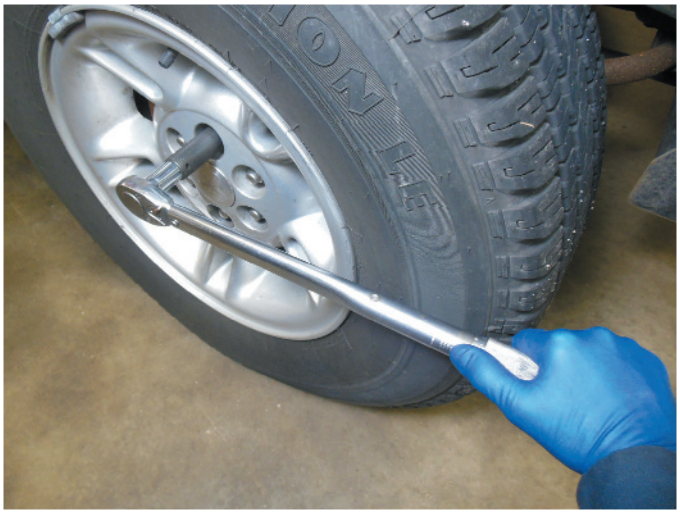

FIGURE 110–14 A torque wrench being used to tighten lug nuts on a pickup truck.

The use of torque-absorbing adapters (*torque sticks*) on lug nuts with an air impact wrench properly set has proved to give satisfactory results as long as the specified air pressure is used and that they are used according to the torque-absorbing instructions. ● **SEE FIGURE 110–15**.

If the exact torque value is not available, ● **SEE CHART 110–1** as a guide for the usual value based on the size (diameter) of the lug studs.

TIRE ROTATION

PURPOSE **Tire rotation** is essential to ensure long life and even tire wear. It is important to rotate each tire to another location. Some rear-wheel-drive vehicles, for example, may show premature tire wear on the front tires. The wear usually starts on the outer tread row. It usually appears as a front-to-back (high and low) wear pattern on individual tread blocks. These *blocks of tread* rubber are deformed during cornering, stopping, and turning. This type of tread block wear can cause tire noise and/or tire roughness.

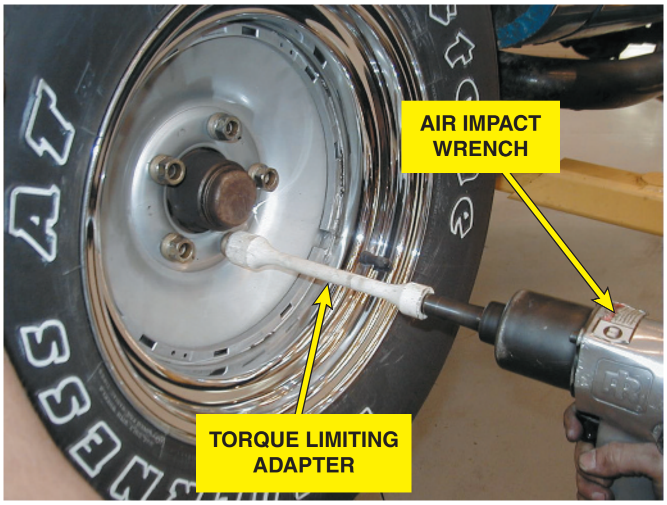

FIGURE 110–15 A torque-limiting adapter (torque stick) used with an air impact wrench still requires care to prevent overtightening. The air pressure to the air impact should be limited to 125 PSI (860 kPa) in most cases, and the proper adapter must be selected for the vehicle being serviced. The torque adapter absorbs any torque beyond its designed rating. Most vehicle manufacturers recommend that final tightening be performed using a torque wrench.

CHART 110–1

Typical lug nut torque based on the diameter of the wheel stud.

CASE STUDY

I Thought the Lug Nuts Were Tight!

Proper wheel nut torque is critical, as one technician discovered when a customer returned complaining of a lot of noise from the right rear wheel. The lug (wheel) nuts had loosened and ruined the wheel. ● **SEE FIGURE 110–16**.

CAUTION: Most vehicle manufacturers also specify that the wheel studs/nuts should not be lubricated with oil or grease. The use of a lubricant on the threads could cause the lug nuts to loosen.

Summary:

Complaint—Customer complained of a lot of noise from the rear of the vehicle after a routine tire rotation.
Cause—The service technician got distracted when installing the wheels during a tire rotation and forgot to properly torque the lug nuts.
Correction—A new wheel was used and the tire mounted and balanced and properly installed.
The technician learned to always keep focused on the job being performed.

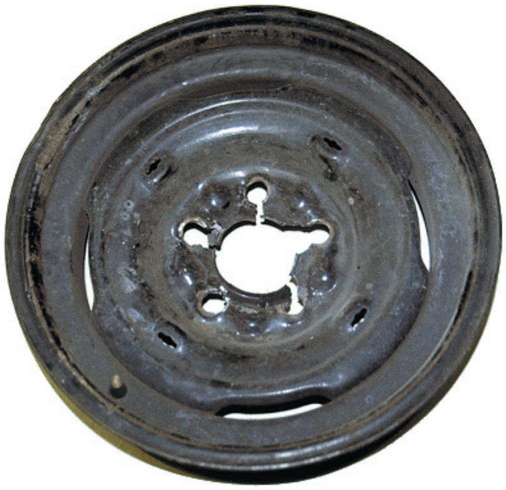

FIGURE 110–16 This wheel was damaged because the lug nuts were not properly torqued.

TECH TIP

All-Wheel-Drive Tire Concerns

It is very important that all-wheel-drive vehicles be equipped with tires that are all the same outside diameter. If, for example, the vehicle has 20,000 miles and the tires are half worn, all of the tires should be replaced in the event of a problem requiring replacement of only one tire. Most vehicle manufacturers specify that all tires must be within 2/32 inch of tread depth without causing a constant strain on the drivetrain.

While some shoulder wear on front tires is normal, it can be reduced by proper inflation, alignment, and tire rotation.

METHODS For best results, tires should be rotated every 6,000 miles or every six months. ● **SEE FIGURE 110–17** for suggested methods of rotation, such as the **modified X**.

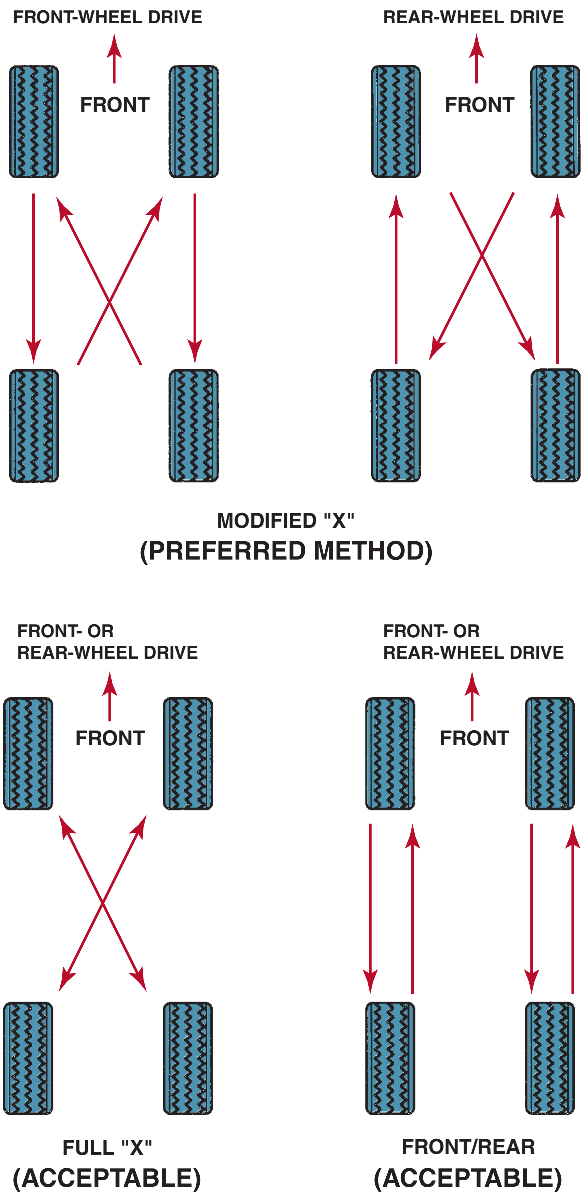

FIGURE 110–17 The method most often recommended is the modified X method. In this method, each tire eventually is used at each of the four wheel locations. An easy way to remember the sequence, whether front-wheel drive or rear-wheel drive, is to say to yourself, "Drive wheels straight, cross the nondrive wheels."

NOTE: Radial tires can cause a radial pull due to their construction. If wheel alignment is correct, attempt to correct a pull by rotating the tires front to rear or, if necessary, side to side.

RADIAL RUNOUT

WHY CHECK Even though a tire has no visible faults, it can be the cause of vibration. If vibration is felt above 45 MPH, regardless of the engine load, the cause is usually due to an out-of-balance or a defective out-of-round tire. Both of these problems cause a **tramp**, which is an up-and-down-type vibration. If the vibration is seen in the hood of the vehicle or felt in the steering wheel, then the problem is usually the *front* tires. If the vibration is felt throughout the entire vehicle or in the seat of your pants, then the rear tires (or drive shaft, in rear-wheel-drive vehicles) are the problem.

CHECKING RADIAL RUNOUT This can be checked by using a runout gauge. ● **SEE FIGURES 110–18 AND 110–19**.

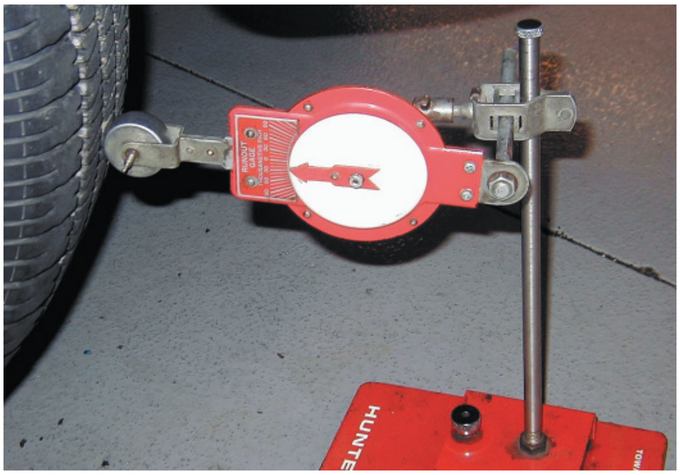

FIGURE 110–18 A tire runout gauge being used to measure the radial runout of a tire.

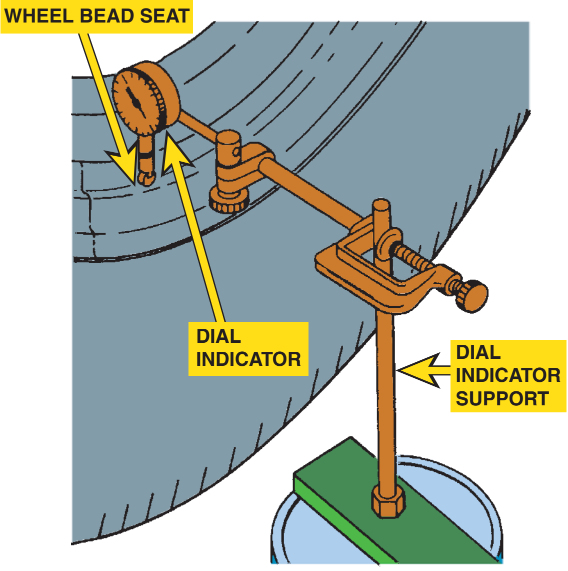

FIGURE 110–19 To check wheel radial runout, the dial indicator plunger tip rides on a horizontal surface of the wheel, such as the bead seat.

To check **radial runout** (checking for out of round) and **lateral runout** (checking for side-to-side movement), perform the following steps:

STEP 1 Raise the vehicle so that the tires are off the ground approximately 2 inches (5 cm).

STEP 2 Place the runout gauge against the tread of the tire in the center of the tread and, while rotating the tire, observe the gauge reading.

STEP 3 Note that maximum radial runout should be less than 0.060 inch (1.5 mm). Little, if any, tramp will be noticed with less than 0.030 inch (0.8 mm) runout. If the reading is over 0.125 inch (3.2 mm), replacement of the tire is required.

STEP 4 Check all four tires.

CORRECTING RADIAL RUNOUT Excessive radial runout may be corrected by one of several methods:

Method **#1.** Try relocating the wheel on the mounting studs. Mark one stud and remount the wheel two studs away from its original position. Excessive wheel hole and/or stud tolerance may be the cause. If the radial runout is now satisfactory, remark the stud and wheel to prevent a future occurrence of the problem.

Method **#2.** Remount the tire on the wheel 180 degrees from its original location. This can solve a runout problem, especially if the tire was not match mounted to the wheel originally.

Method **#3.** If runout is still excessive, remove the tire from the wheel and check the runout of the *wheel.* If the wheel is within 0.035 inch (0.9 mm), yet the runout of the tire/wheel assembly is excessive, the problem has to be a defective tire and it should be replaced.

Sometimes a problem within the tire itself can cause a vibration, and yet not show up as being out of round when tested for radial runout. A condition called **radial force variation (RFV)** can cause a vibration even if correctly balanced. Many tire balancers are equipped with a roller that is pressed against the tread of the tire to measure radial force variations. Follow the instructions as shown on the balancer display to correct for excessive radial force variations. ● **SEE FIGURE 110–20**.

LATERAL RUNOUT

WHY CHECK A possible problem that tires can cause is a type of vibration called **shimmy**, which is the rapid back-and-forth motion transmitted through the steering linkage to the steering wheel. Excessive lateral runout is usually noticeable by the driver of the vehicle as a side-to-side vibration, especially at low speeds between 5 and 45 mph (8 and 72 km/h). Shimmy can be caused by an internal defect of the tire or a bent wheel.

CHECKING LATERAL RUNOUT This can be checked by using a runout gauge on the side of the tire or wheel. Place the runout gauge against the side of the tire and rotate the wheel. Observe the readings.

- Most manufacturers specify a maximum lateral runout of 0.035 inch (0.9 mm) for alloy wheels and 0.045 inch (1.1 mm) for steel wheels. ● **SEE FIGURE 110–21**.

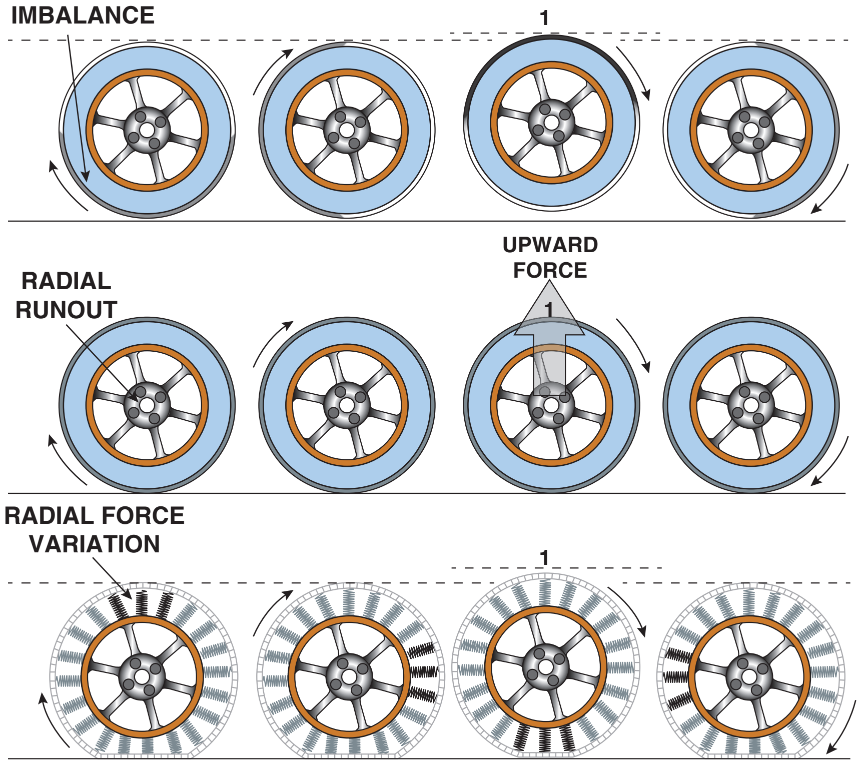

FIGURE 110–20 Out-of-balance causes the wheel/tire to move vertically as it rotates causing a tramp-type vibration. Excessive radial runout also causes a tramp-type vibration. Excessive radial force variation (RFV) can cause a vibration due to the varying stiffness of the tire carcass.

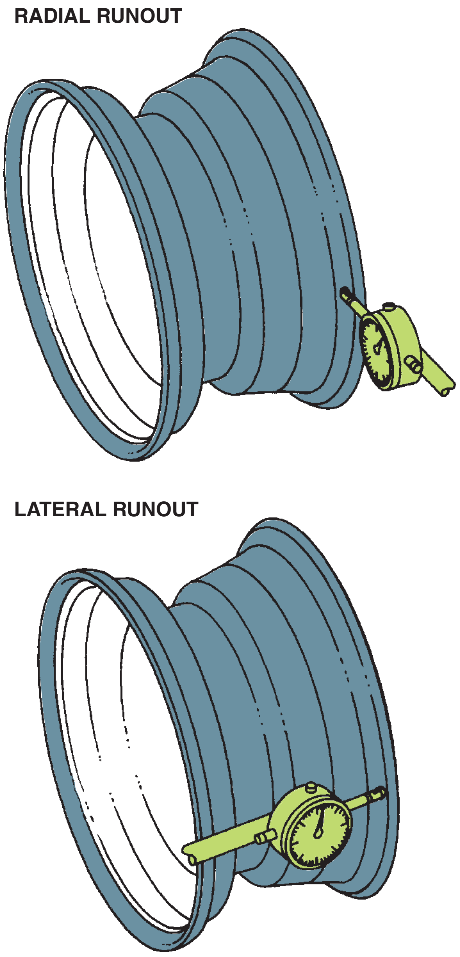

FIGURE 110–21 The most accurate method of measuring wheel runout is to dismantle the tire and take dial indicator readings on the inside of the wheel rim.

CORRECTING LATERAL RUNOUT Excessive lateral runout may be corrected by one of several methods:

Method **#1—**Re-torque the wheel in the proper star pattern to the specified torque. Unequal or uneven wheel torque can cause excessive lateral runout.

Method **#2—**Remove the wheel and inspect the wheel-mounting flange for corrosion or any other reason that could prevent the wheel from seating flat against the brake rotor or drum surface.

Method **#3—**Check the condition of the wheel or axle bearings. Looseness in the bearings can cause the wheel to wobble.

TIRE REPLACEMENT

REMOVING WHEEL/TIRE ASSEMBLY When removing a wheel from a vehicle for service, perform the following steps:

STEP 1 Check the operation of the tire-pressure monitoring system (TPMS) sensor using a handheld tester before removing the wheel so the customer can be warned about a defective sensor before the wheels are removed from the vehicle.

STEP 2 Make certain that the wheel has a good, clean metal-to-metal contact with the brake drum or rotor. Grease, oil, or dirt between these two surfaces could cause the wheel lug nuts to loosen while driving.

TIRE REMOVAL FROM THE WHEEL Tire removal from a wheel procedure includes the following steps:

STEP 1 Before the tire can be removed from the wheel, the air must be removed by removing the valve core. Removing the valve core allows the air to escape.

TECH TIP

Spin the Tires

When performing a vehicle inspection and the vehicle has been hoisted on a frame-type lift, check the tires by rotating them by hand. The tires on the non-drive wheels should spin freely.

- On front-wheel-drive vehicles, rear wheels should rotate easily.
- On rear-wheel-drive vehicles, front wheels should rotate easily.
- On all-wheel-drive vehicles, all four wheels may require effort to rotate.

What to Look For?

- When rotating the wheels, look at the tires from the front or rear and check that the tread of the tires does not change or look as if the tread is moving inward or outward. If the tread is moving, this indicates an internal fault with the tire and it should be replaced. This type of fault can cause a vibration even though the tire/wheel assembly has been correctly balanced.
- Look from the side of the vehicle as the wheel/tire assembly is being rotated. Look carefully at the tread of the tire and see if the tire is round. If the tire is out of round, the tread will appear to move up and down as the tire is being rotated.

TECH TIP

Think Like a Wheel

When mounting directional tires, keep in mind which direction the wheels will be rotating when the vehicle is moving forward.

- When looking at the right side of the vehicle, the wheels will be rotating in a clockwise direction.
- When looking at the left side of the vehicle, the wheels will be rotating counterclockwise.

STEP 2 After the air has been removed from the tire, the beads are broken from both sides. Use caution when working on a wheel that has TPMS so as to not harm the sensor. Position the valve stem 90 degrees away from the bead breaker shovel to protect the sensor.

STEP 3 Remove the tire from the rim following the tire machine instructions for proper use.

INSTALLING NEW TIRES

STEP 1 Clean the wheel flange (seat bead) of any dirt, scale, corrosion, or loose or flaked rubber buildup prior to mounting the tire to insure of a proper seal. ● **SEE FIGURE 110–22.**

STEP 2 Install the tire-pressure monitoring system in the specified position. ● **SEE FIGURE 110–23.**

STEP 3 Many tires have been marked with a paint dot or sticker. ● **SEE FIGURE 110–24.** This mark represents the largest diameter (high point) and/or stiffest portion of the tire. This variation is due to the overlapping of carcass and belt fabric layers, as well as tread and sidewall rubber splices. The tire should

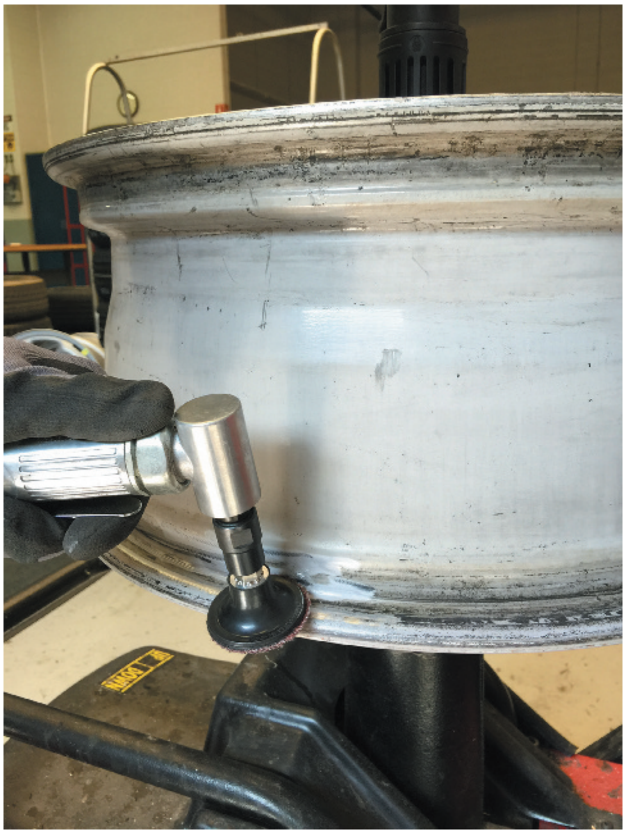

FIGURE 110–22 Cleaning the bead seat of an alloy wheel using an abrasive pad.

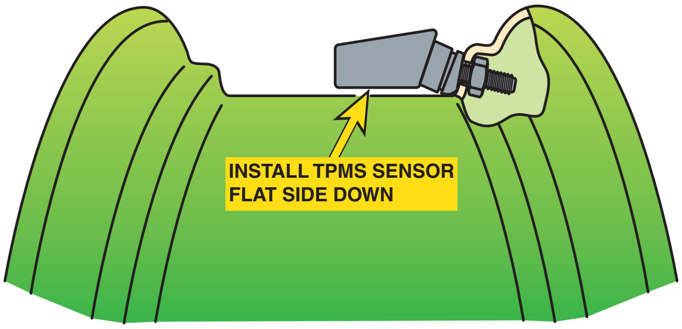

FIGURE 110–23 When installing a tire-pressure monitoring system sensor, be sure that the flat part of the sensor is parallel to the center section of the rim.

TECH TIP

Dispose of Old Tires Properly

Old tires cannot be thrown out in the trash but instead must be disposed of properly. Tires cannot be buried because they tend to come to the surface. They also trap and hold water, which can be a breeding ground for mosquitoes. Used tires should be sent to a local or regional recycling center where the tires will be ground up and used in asphalt paving or other industrial uses. Because there is often a charge to dispose of old tires, it is best to warn the customer of the disposal fee.

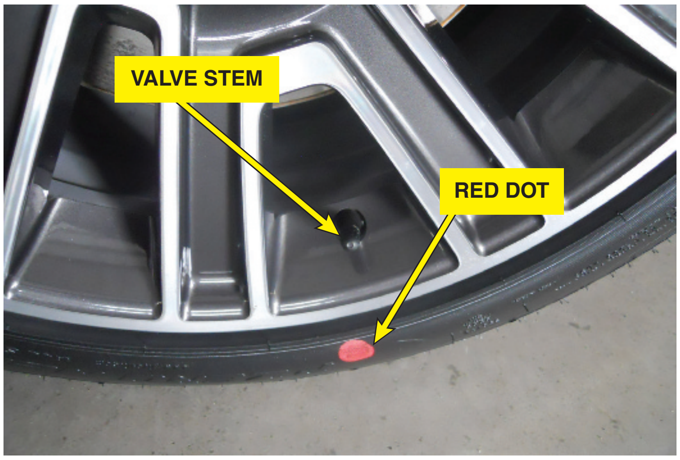

FIGURE 110–24 Many new tires have painted dots placed there at the tire manufacturer. Yellow Dot Indicates the light (static) balance point of the tire. Red Dot Indicates the "radial force variation first harmonic maximum." If a tire has both red and yellow dots, the red dot has priority so ignore the yellow dot. Match the yellow dot to the wheel valve stem if no red dot. Just remember "red rules." If any other color of dot is seen, ignore them as they are used for factory purposes only.

be mounted to the rim with this mark lined up with the valve stem.

- The valve stem hole is typically drilled at the smallest diameter (low point) of the wheel.
- The major splice is usually at the largest diameter of the tire.
- On steel rims, align the mark on the tire with the dimple on the rim (if used). This is called **match mounting**. ● **SEE FIGURE 110–25**.

STEP 4 Check for directional and asymmetric tires.

- Directional tires have the direction of rotation arrow on the sidewall of the tire.

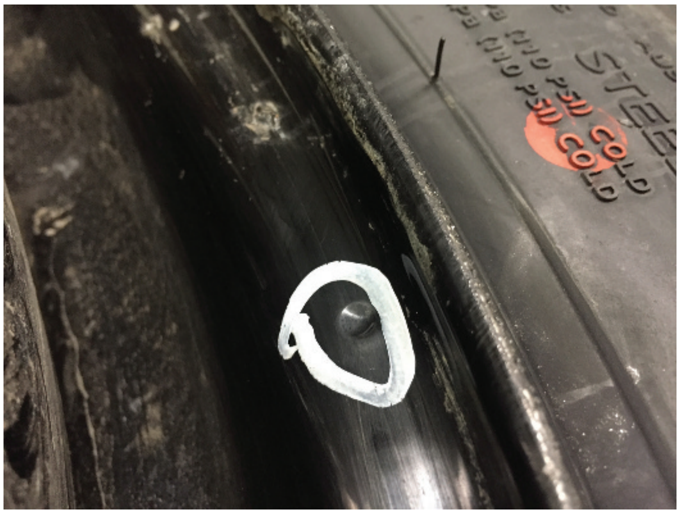

FIGURE 110–25 Most steel wheels are not as round as alloy wheels that are machined as part of the production process. Look for a "dimple" on the steel wheel and align the red dot of the tire with this dimple when match mounting tires on steel wheels. If there is no dimple, align the red dot with the valve stem.

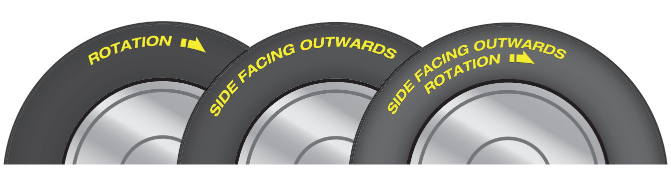

FIGURE 110–26 Always check the wording on tires and install them correctly to insure that the tire performs as designed.

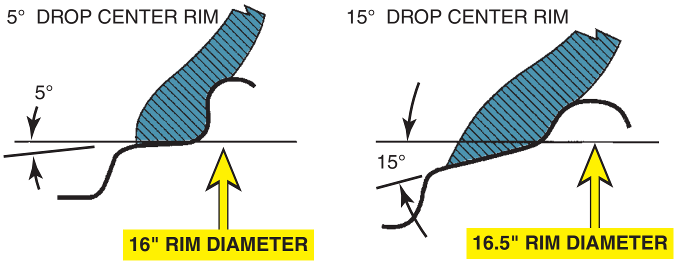

FIGURE 110–27 Note the difference in the shape of the rim contour of the 16 inch and 16 1/2 inch diameter wheels. While it is possible to mount a 16 inch tire on a 16 inch rim, it cannot be inflated enough to seat against the rim flange. If an attempt is made to seat the tire bead by overinflating (over 40 PSI), the tire bead can break, resulting in an explosive force that could cause serious injury or death.

- Asymmetric tires have sidewall lettering indicating which side of the tire has to face outward.
- Directional and asymmetric tires have "side facing outwards" and a rotation arrow showing the direction of rotation when the vehicle is traveling forward. ● **SEE FIGURE 110–26**.

CAUTION: Always check the rim size. For example, simply by looking, it is hard to distinguish a 16 inch wheel from a 16.5 inch wheel used on some older trucks. The rim size is marked on the sidewall of the tire, and the rim's diameter and width are stamped somewhere on the wheel. ● SEE FIGURE 110–27.

STEP 5 When mounting new tires, use only special lubricant such as rendered (odorless) animal fat or rubber lubricant to help prevent tire rotation on the rim. This rubber lube is a water-based soap product that is slippery when wet (coefficient of friction when less than 0.3) and acts almost as an adhesive when dry (coefficient of friction when dry of over 0.5 for natural products and over 1.0 for synthetic products). ● **SEE FIGURE 110–28**.

STEP 6 Inflate the tire but never use more than 40 PSI (275 kPa) to seat a tire bead.

NOTE: Many experts recommend that when a new tire is installed, the vehicle should be driven at less than 50 mph (80 km/h) for the first 50 miles (80 km) to allow the tires to adhere to the rim. During this break-in period, the rubber lube used to mount the tire is drying and the tire is becoming fully seated on the rim. By avoiding high speeds, rapid acceleration, and fast braking, the driver is helping to prevent the tire from rotating on the rim.

FIGURE 110–28 Rendered (odorless) animal fat is recommended by some manufacturers of tire changing equipment for use as a rubber lubricant.

TIRE BALANCING

PURPOSE Proper tire balance is important for tire life, ride comfort, and safety. Tire balancing is needed because of the lack of uniform weight and stiffness (due to splices) and a combination of wheel runout and tire runout. While balancing a tire can compensate for most of these conditions, if a tire or wheel is excessively out of round or bent, then replacement of the wheel or tire is required.

STATIC BALANCE The term *static balance* means that the weight mass is evenly distributed around the axis of rotation. For example:

- If a wheel is spun and stops at different places with each spin, then the tire is statically balanced.
- If the static balance is not correct, wheel tramp-type (vertical up and down shake) vibration and uneven tire wear can result.

DYNAMIC BALANCE The term *dynamic balance* means that the centerline of weight mass is in the same plane as the centerline of the wheel. ● **SEE FIGURE 110–29**.

- Dynamic balance must be checked while the tire and the wheel are rotated to determine side-to-side as well as up-and-down out of balance.
- Incorrect dynamic balance causes shimmy. Shimmy-type vibration causes the steering wheel to shake from side to side.

Computer tire balance machines balance tires for both static and dynamic balance at the same time.

PREBALANCE CHECKS Before attempting to balance any tire, the following should be checked and corrected to ensure good tire balance:

1. Check the wheel bearing adjustment for looseness or wear.
2. Check the radial runout.
3. Check the lateral runout.
4. Remove stones from the tread.

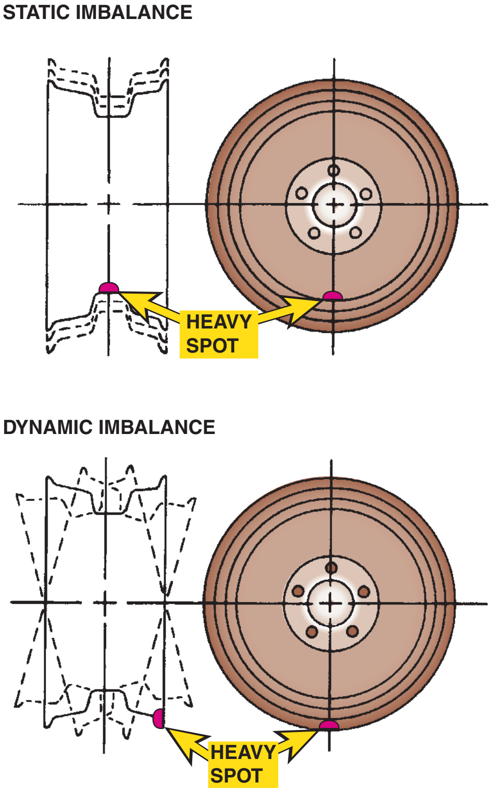

FIGURE 110–29 A wheel balancer detects heavy spots on the wheel and tire, and indicates where to place weight to offset both static and dynamic imbalance.

5. Remove grease or dirt buildup on the inside of the wheel.
6. Check for dragging or misadjusted brakes.
7. Check for loose or backward lug nuts.
8. Check for proper tire pressures.
9. Remove all of the old weights.
10. Check for bent or damaged wheel covers.

WHEEL WEIGHTS

PURPOSE AND FUNCTION The purpose and function of wheel weights is to correct any imbalance that can normally occur in a tire/wheel assembly. This imbalance can cause the wheels to hop when rotating causing a vibration that is felt by the driver in the steering wheel, and often the entire vehicle, especially if the rear wheels are out of balance.

WHEEL WEIGHT MATERIALS Lead was the most common material used for wheel weights until the early 2000s when they started to be phased out due to environmental concerns of lead on the ground from lost wheel weights.

Wheel balancing materials include

- **Lead** (chemical symbol PB)—being phased out (stick-on and clip-on designs)
- **Zinc** (chemical symbol ZN)—(stick-on and clip-on designs)
- **Steel** (chemical symbol FE)—(stick-on and clip-on designs)
- **Thermoplastic Polypropylene**—high specific gravity plastic (stick-on only)

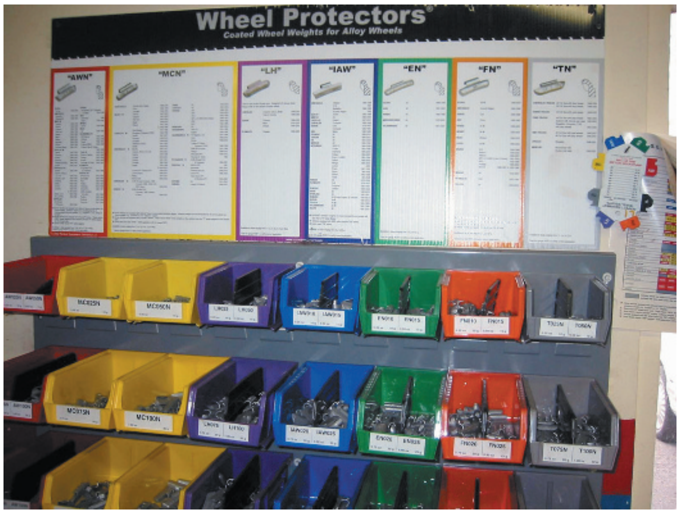

FIGURE 110–30 An assortment of wheel weights designed to fit different shaped rims.

Steel wheel weights are usually coated with a nylon or polyester-type material that often matches the color of the aluminum wheels to prevent rust and corrosion of the steel.

CLIP-ON WHEEL WEIGHTS Clip-on wheel weights must match the flange of the rim to fit properly. Use wheel weight pliers to help ensure proper installation and removal of wheel weights. ● **SEE FIGURE 110–30**.

FREQUENTLY ASKED QUESTION

Does "MC" Mean "Most Cars"?

Maybe. MC is the wheel flange shape that is used on most domestic alloy rims. The next most popular shape is "AW," which is used on older GM, Ford, and Chrysler alloy rim and then "FN" which is used on many Acura, Honda, Nissan, and Toyotas since about 1990. To be sure, always use a rim flange gauge to determine the exact shape before using clip-on wheel weights. ● **SEE FIGURE 110–31**.

● **SEE CHART 110–2** for the wheel rim flange shape for most vehicles.

STICK-ON WHEEL WEIGHTS Adhesive (stick-on) wheel weights are used on the inside of the rim where they do not show. Stick-on weights come with an adhesive backing that is most often used on alloy wheels. ● **SEE FIGURES 110–32 AND 110–33**.

Most wheel weights come in 1/4 ounce (0.25 oz.) increment (oz. × 28 = grams). ● **SEE CHART 110–3** for a conversion between ounces and grams.

Use wheel weight pliers to help ensure proper installation and removal of wheel weights.

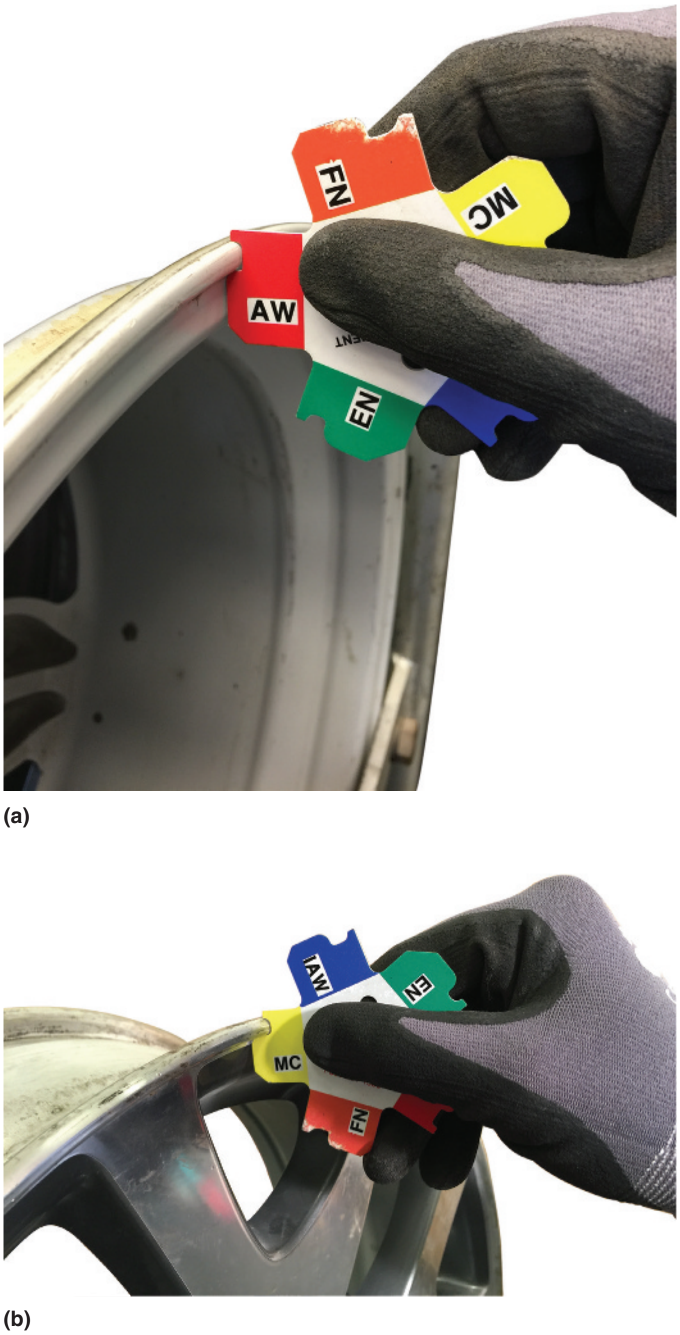

FIGURE 110–31 (a) Using a rim gauge can be a little tricky as the shape may appear to match several patterns on the rim gauge. This "AW" shape is not a good match. (b) Using the gauge shape for "MC" appears to be a perfect match to their rim flange.

FREQUENTLY ASKED QUESTION

How Much Is Too Much Weight?

Whenever balancing a tire, it is wise to use as little amount of weight as possible. For most standard-size passenger vehicle tires, most experts recommend that no more than 5.5 ounces of total weight be added to correct an imbalance condition. If more than 5.5 ounces total or more than 3 ounces on either side is needed, remove the tire from the wheel (rim) and carefully inspect for damage to the tire or the wheel. If the tire still requires more than 5.5 ounces and the wheel is not bent or damaged, replace the tire.

WHEEL/TIRE BALANCERS

BUBBLE BALANCER A bubble balancer is portable and can be easily stored away when not in use. It is also easy to use and is relatively inexpensive but not as accurate as a professional tire balancing machine.

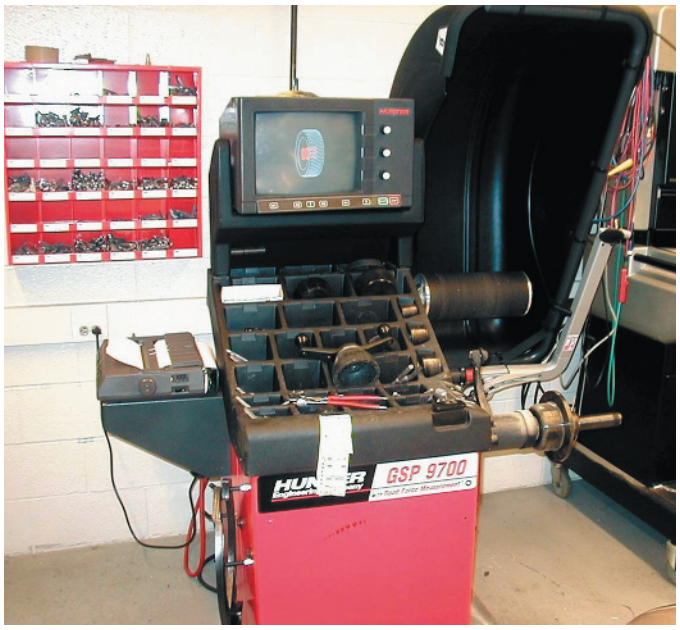

FIGURE 110–34 A tire balancer that can also detect radial and lateral force variation and instruct the operator where to rotate the tire to achieve the best ride, or indicate a bent wheel.

COMPUTER BALANCER The most popular type of tire balancer is the computer dynamic balancer. Computer balancers are designed to balance wheels and tires off the vehicle. Computer dynamic balancers spin the tire at a relatively slow speed (approximately 20 mph). Sensors attached to the spindle of the balancer determine the amount and location of weights necessary to balance the tire statically and dynamically. All computer balancers must be programmed with the actual rim size and tire location for the electronic circuits to calibrate the required weight locations. Some computer balancers can perform loaded radial force and lateral force variation testing on the tire/wheel assembly and display corrective actions. ● **SEE FIGURE 110–34**.

Most computer balancers will be accurate to within 1/4 ounce (0.25 oz.), while some are accurate to within 1/8 ounce

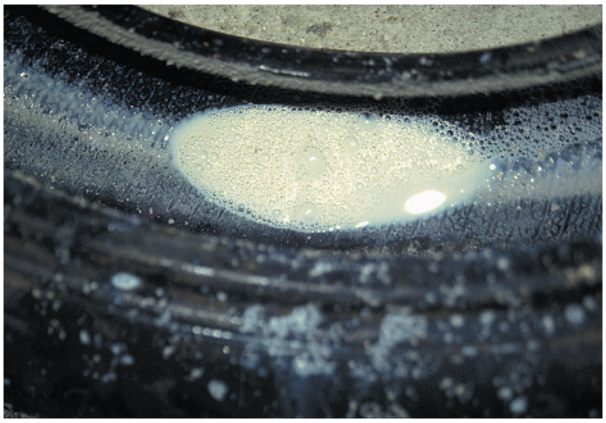

FIGURE 110–35 Liquid tire stop leak was found in all four tires. This liquid caused the tires to be out of balance.

FREQUENTLY ASKED QUESTION

When Are Pin Plates Used When Tire Balancing?

Pin plates are often specified to attach a chrome clad wheel to the tire balancers to insure an accurate balance. The chrome cladding is not removable or replaceable and has cladding tabs that extend into the wheel bore. Traditional high-taper cones will come into contact with the cladding tabs rather than properly seat on the hub bore chamfer. Many recent aluminum wheel designs cannot be mounted with traditional cones.

Most vehicle manufacturers recommend using a pin plate clamping method as the only way to properly center and protect clad wheels during the balance process. Most balance manufacturers have clad wheel packages along with standard cone mounting. Some national tire chains use only pin plates when balancing any wheel because they get better results and it eliminates some operator influence when using a cone in the center bore. ● **SEE FIGURE 110–36**.

CASE STUDY

The Vibrating Ford Van

A technician was asked to solve a vibration problem on a rear-wheel-drive Ford van. During a test-drive, the vibration was felt everywhere—the dash, the steering wheel, the front seat, the shoulder belts; everything was vibrating! The technician balanced all four tires on a computer balancer. Even though wheel weights were put on all four wheels and tires, the vibration was even worse than before. The technician rebalanced all four wheels time after time, but the vibration was still present. The shop supervisor then took over the job of solving the mystery of the vibrating van. The supervisor balanced one wheel/tire assembly and then tested it again after installing the weights. The balance was way off! The supervisor broke the tire down and found about 1 quart (1 liter) of liquid in each tire! No wonder the tires couldn't be balanced! Every time the tire stopped, the liquid would settle in another location. The customer later admitted to using a tire stop-leak liquid in all four tires. Besides stop leak, another common source of liquid in tires is water that accumulates in the storage tank of air compressors, which often gets pumped into tires when air is being added. All air compressor storage tanks should be drained of water regularly to prevent this from happening. ● **SEE FIGURE 110–35**.

Summary:

Complaint—Customer complained of a vibration.
Cause—The technician found stop leak liquid in all four tires.
Correction—The stop leak was removed from all the tires and then they were rebalanced. The vibration issues were corrected.

CAUTION: Stop leak should never be used in a tire that is equipped with the TPMS sensor because the sensor can be damaged.

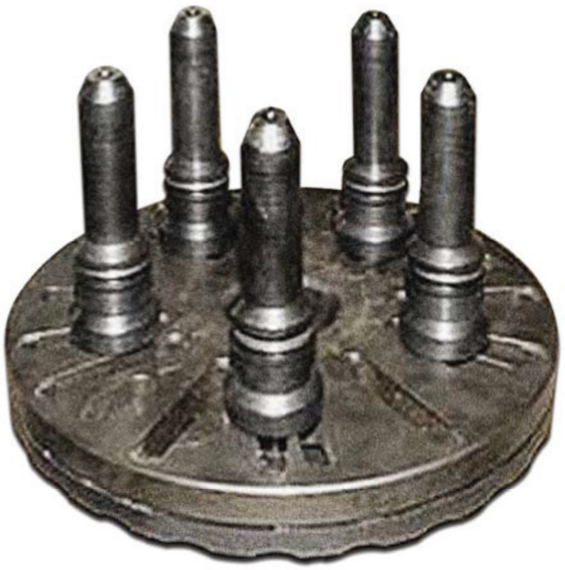

FIGURE 110–36 A pin plate adapter that is designed to support the wheel/tire assembly on a tire balancer instead of using a centering cone.

FREQUENTLY ASKED QUESTION

What Are Hubcentric Wheels?

Most wheels are designed to fit over and be supported by the axle hub. Some wheels use an enlarged center hub section and rely on the wheel studs for support and to keep the wheel centered on the axle. Some aftermarket wheels may be designed to fit several different vehicles. As a result, the wheel manufacturers use plastic hubcentric adapter rings.
● **SEE FIGURE 110–37**.

(0.125 oz.). (Most drivers can feel an out of balance of 1 oz or more, but few can feel a vibration caused by just 1/4 oz.) For sensitive drivers or vehicles used for high speeds, such as racing, most computer balancers can be programmed to balance within 1/8 ounce (0.125 oz.). Refer to the manufacturer's instructions for the exact capabilities and procedures for the balancer being used.

TIRE REPAIR

ACCEPTABLE LOCATION Tread punctures, nail holes, or cuts up to 1/4 inch (2.6 mm) can be repaired only within the tire repair area. ● **SEE FIGURE 110–38**.

Repairs should be done from the inside of the tire using plugs or patches. The tire should be removed from the rim to make the repair. With the tire off the wheel, inspect the wheel and the tire for hidden damage.

TIRE REPAIR PROCEDURE The proper steps to follow for a tire repair are as follows:

STEP 1 Mark the location of the tire on the wheel.

STEP 2 Dismount the tire and use caution around the tire-pressure monitoring system (TPMS) pressure sensor.

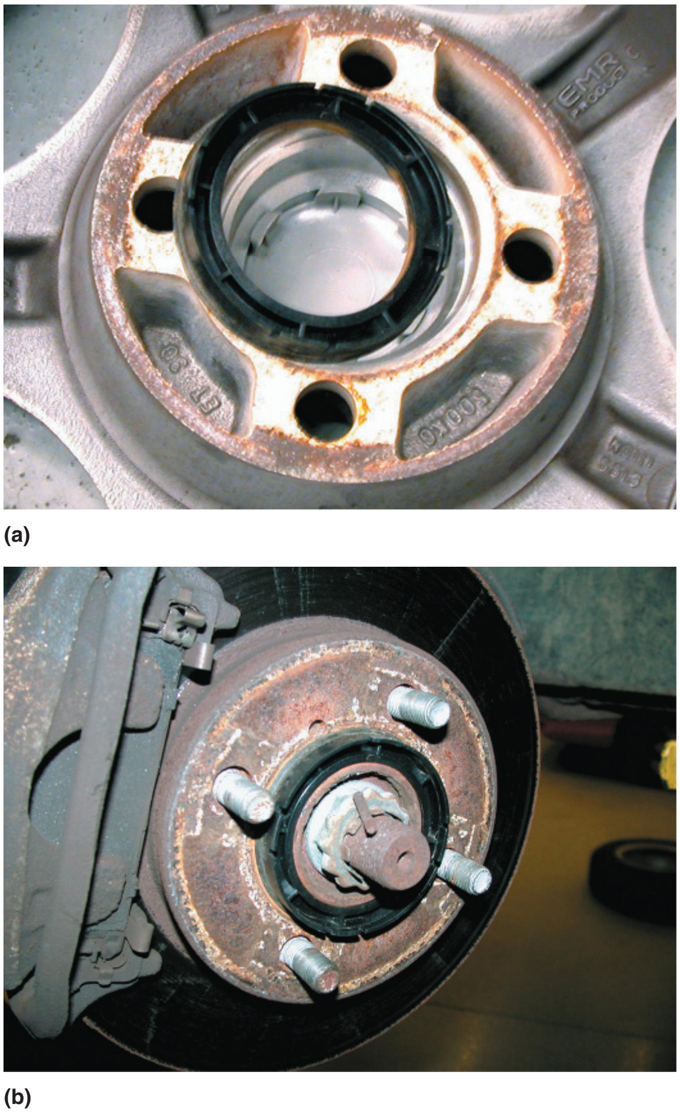

FIGURE 110–37 (a) A hubcentric plastic ring partially removed from an aftermarket wheel. (b) A hubcentric plastic ring left on the hub when removing a wheel.

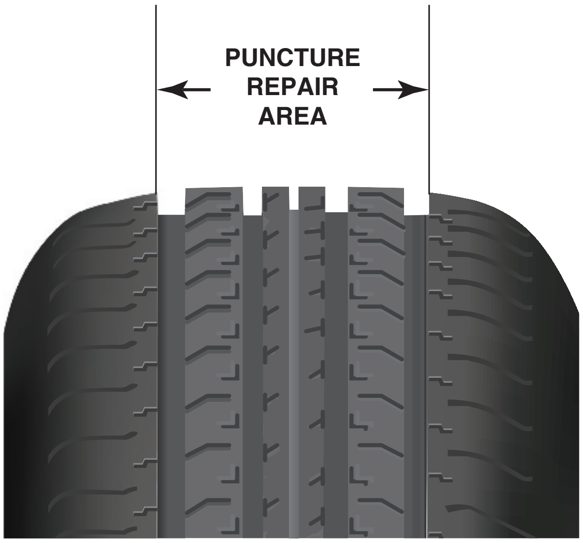

FIGURE 110–38 A tire should only be repaired if the hole is within the tire puncture repair area. Do not make a repair that is located in the shoulder or belt edge part of the tire. If a tire is punctured outside of the area, the tire will require replacement.

WARNING

Most experts agree that tire repairs should be done from the inside. Many technicians have been injured and a few killed when the tire they were repairing exploded as a steel reamer tool was inserted into the tire. The reamer can easily create a spark as it is pushed through the steel wires of a steel-belted tire. This spark can ignite a combustible mixture of gases inside the tire caused by using stop leak or inflator cans. Since there is no way a technician can know if a tire has been inflated with a product that uses a combustible gas, always treat a tire as if it could explode.

STEP 3 Inspect and clean the punctured area with a pre-buff cleaner. DO NOT USE GASOLINE!

STEP 4 Buff the cleaned area with sandpaper or a tire-buffing tool until the rubber surface has a smooth, velvet finish.

STEP 5 Ream the puncture with a fine reamer from the inside. Cut and remove any loose wire material from the steel belts.

STEP 6 Fill the puncture with contour filling material, and cut or buff the material flush with the inner liner of the tire.

STEP 7 Apply chemical vulcanizing cement and allow to dry until it is no longer sticky.

STEP 8 Apply the patch and use a stitching tool from the center toward the outside of the patch to work any air out from between the patch and the tire. ● **SEE FIGURE 110–39**.

Another excellent tire repair procedure uses a rubber plug. Pull the stem through the hole in the tire, as shown in ● **FIGURE 110–40**.

STEP 9 Remount the tire on the rim, aligning the marks made in step 1. Inflate to the recommended pressure and check for air leaks.

STEP 10 Balance the wheel before reinstalling it on the vehicle.

NOTE: Most vulcanizing (rubber) cement is highly flammable. Use out of the area of an open flame. Do not smoke when making a tire repair. There are many tire repair products on the market. Always follow the installation and repair procedures exactly per the manufacturer's instructions.

TECH TIP

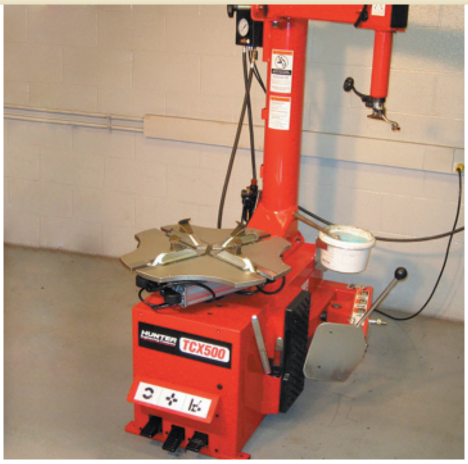
Open-End Wrenches Make It Easier

Tire repair is made easier if two open-end wrenches are used to hold the beads of the tire apart. See step 4 in the tire repair photo sequence.

TIRE MOUNTING

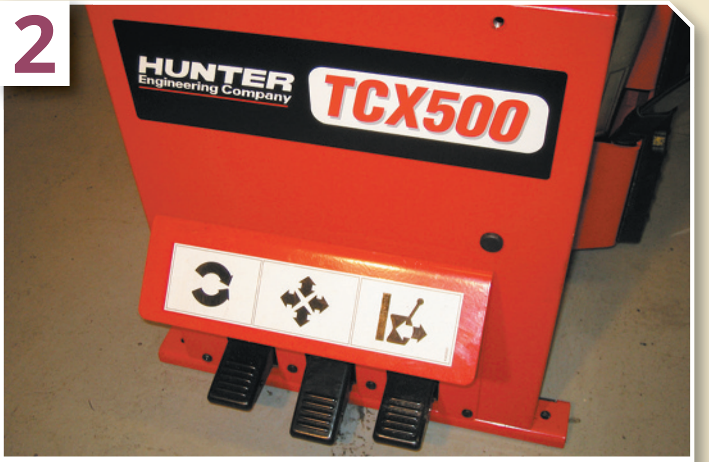
STEP BY STEP

1



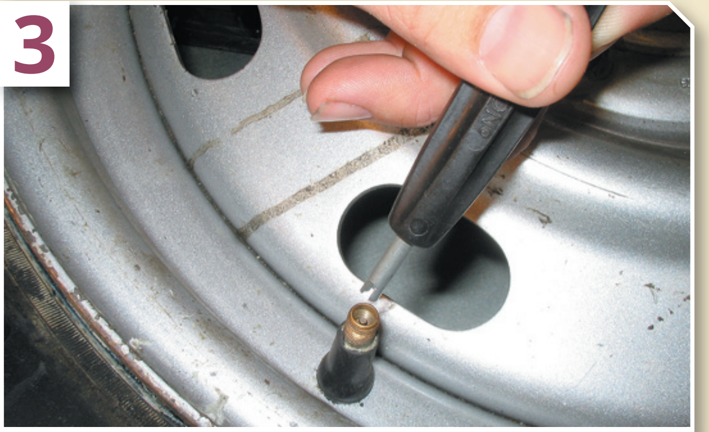
A typical tire-changing machine showing the revolving table and movable arm used to remove a tire from the wheel.

2



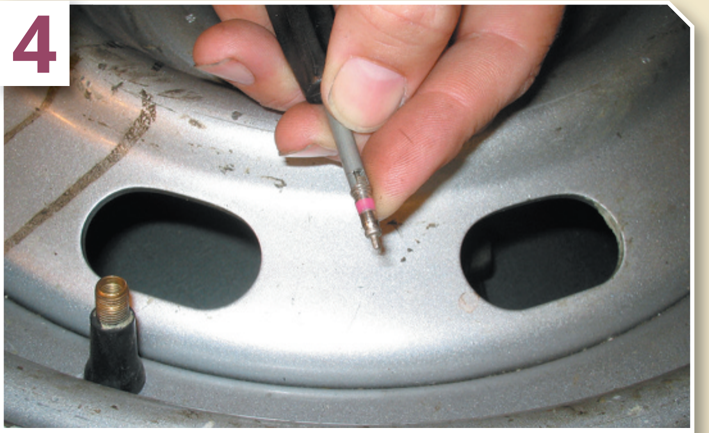
The foot-pedal controls allow the service technician to break the tire bead, damp the wheel (rim) to the machine, rotate the tire/wheel assembly, and still have both hands free.

3



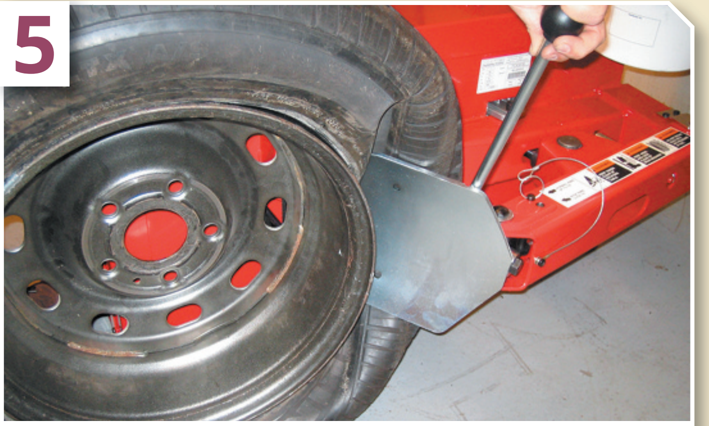
Using a tire valve removal tool, unscrew the valve core using extreme caution because the valve is under pressure and can be forced outward and cause personal injury.

4



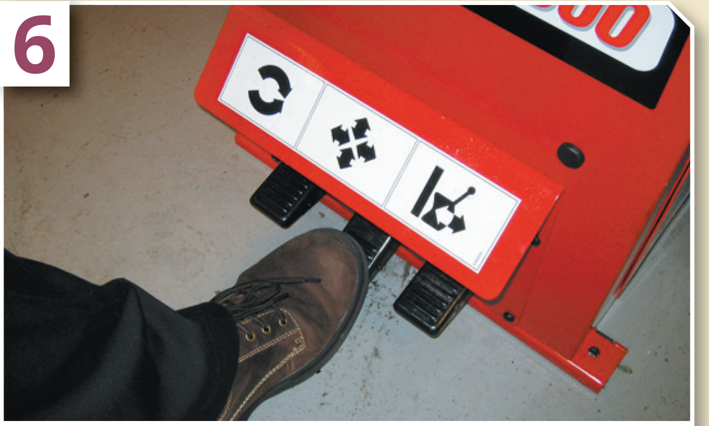
The valve core removed from the tire valve. Allow all of the air in the tire to escape.

5



A bead breaker is being used to separate the tire from the bead seat of the wheel. Repeat as needed to break the bead on both sides of the wheel.

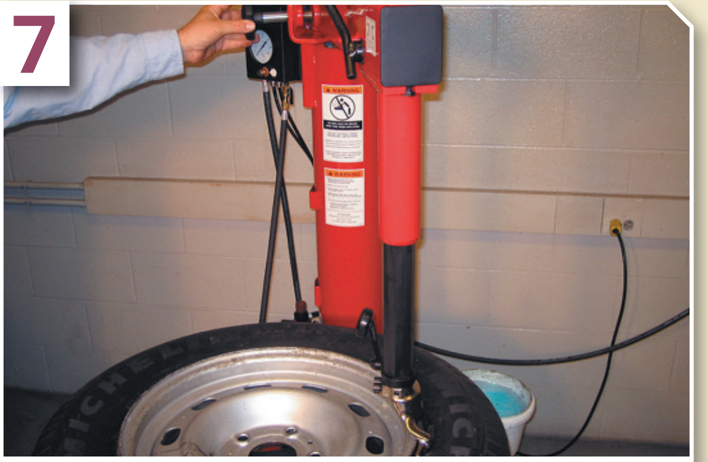
6



After breaking the beads from both sides of the tire, install the wheel/tire assembly flat onto the machine and, using the foot-pedal control, lock the wheel to the changer.

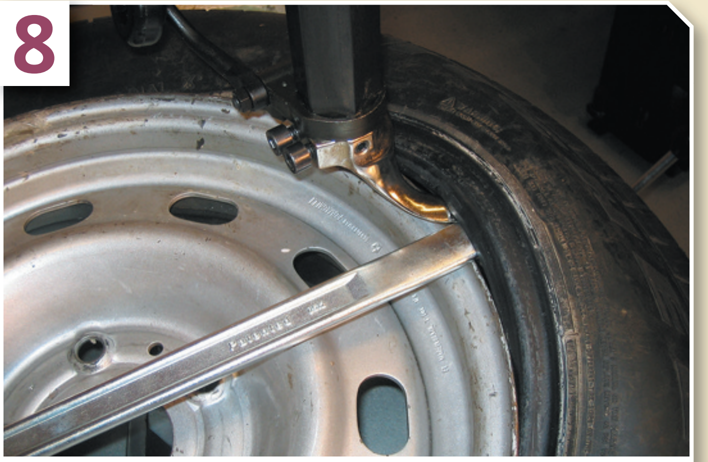
TIRE MOUNTING

7



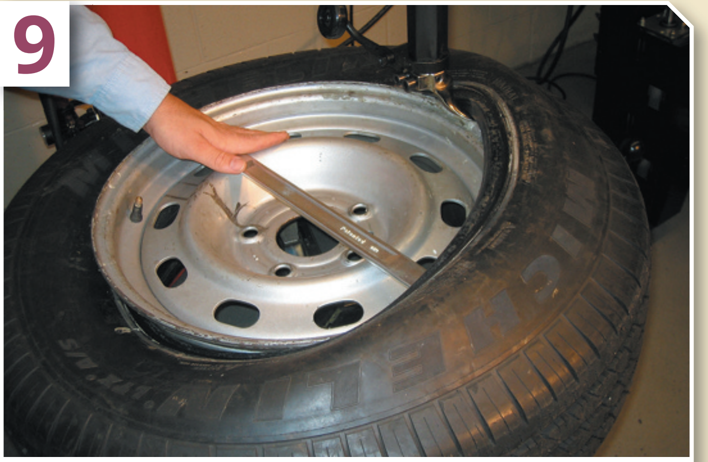
To remove the tire from the wheel, position the arm of the changer against the rim of the wheel and lock in position.

8



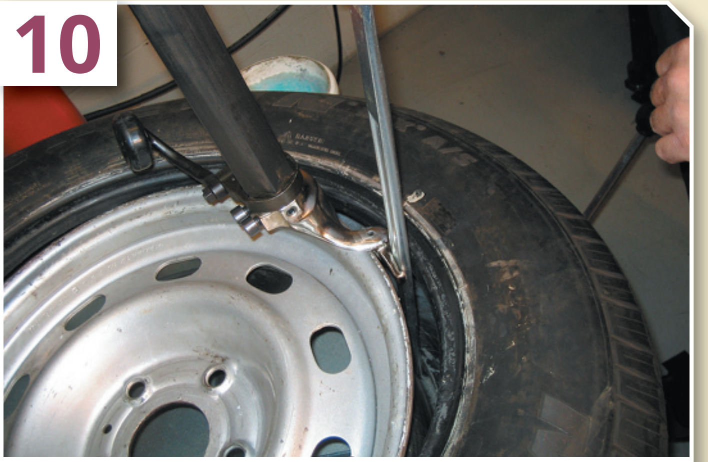
The tire tool (flat bar) is placed between the bead of the tire and the wheel. Using tire lubricant can help prevent damage to the tire.

9



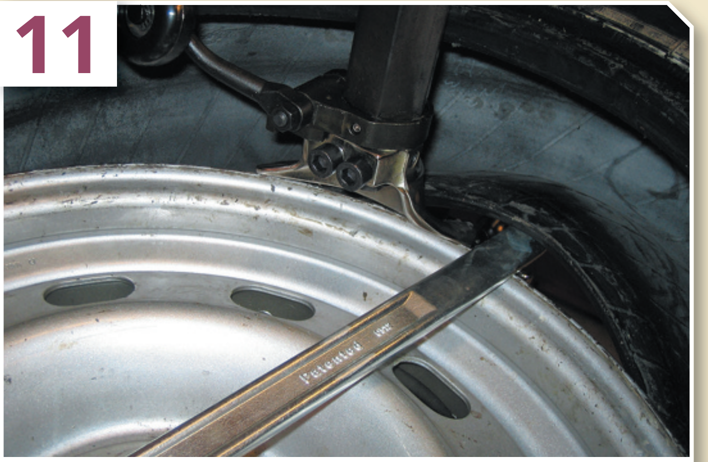
The foot-pedal that causes the table to rotate is depressed and the tire is removed from the wheel.

10



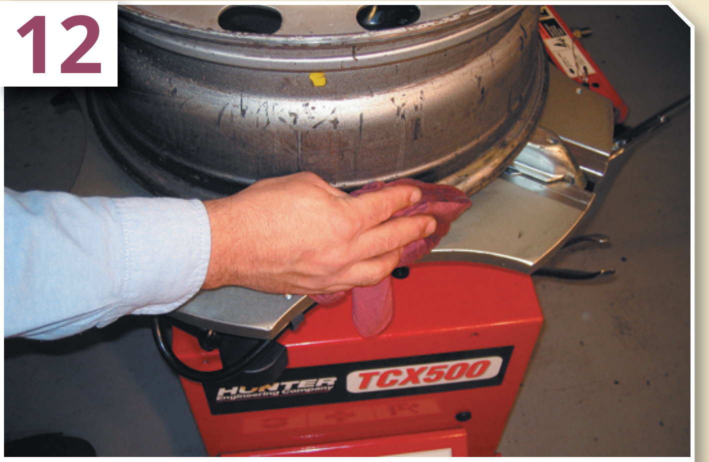
Reposition the tire tool to remove the lower bead of the tire from the wheel.

11



As the table of the tire changer is rotated, the tire is released from the wheel and can be lifted off the wheel.

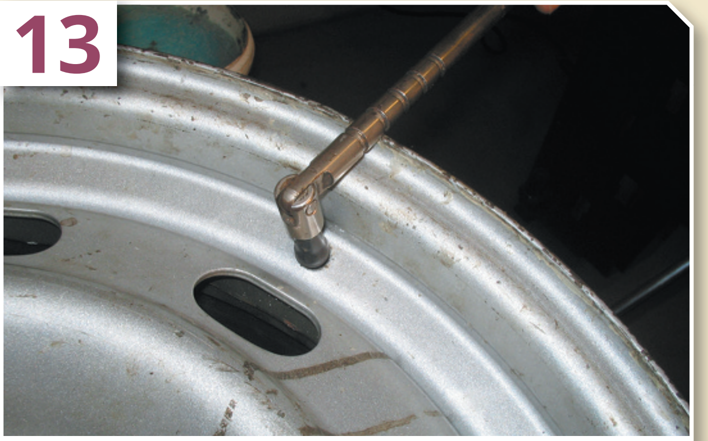
12



Before installing a tire, inspect and clean the bead seat.

STEP BY STEP

13

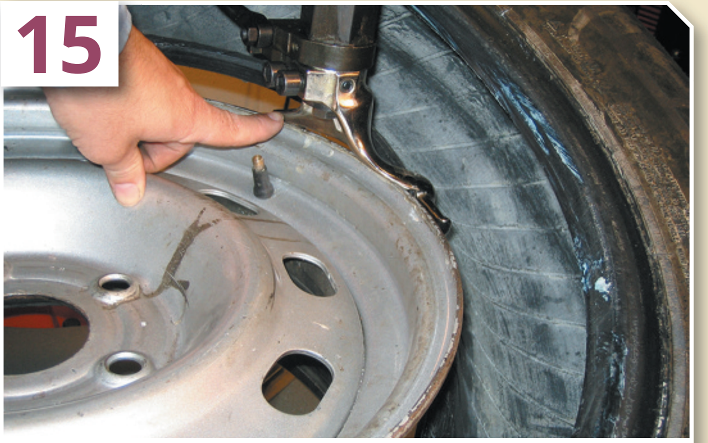


Before installing a new tire, most experts recommend replacing the tire valve, being installed here, using a tool that pulls the valve through the hole in the wheel.

14

Apply tire soap or rubber lubricant to both beads of the tire.

15



Rotate the tire on the wheel and position the arm so that the tire will be guided onto the rim as the wheel is rotated.

16

Repeat for the upper bead.

17

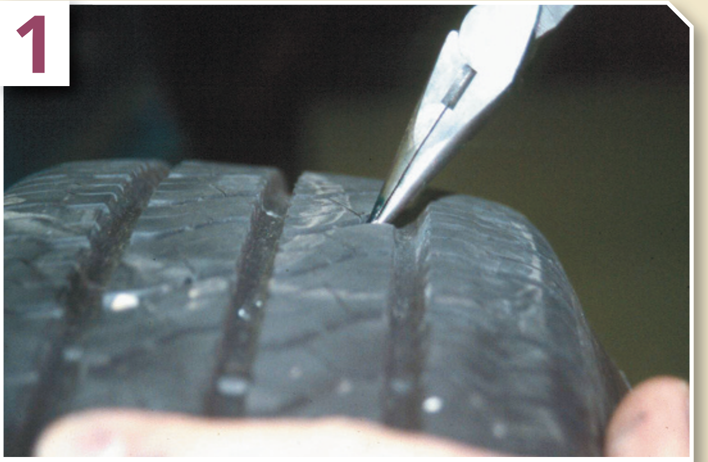
Inflate the tire, being careful to not exceed 40 PSI. Experts suggest that a tire be in a cage during the initial bead seating inflation to help prevent personal injury if the wheel or tire fails.

18

Install the tire valve core and inflate the tire to specifications.

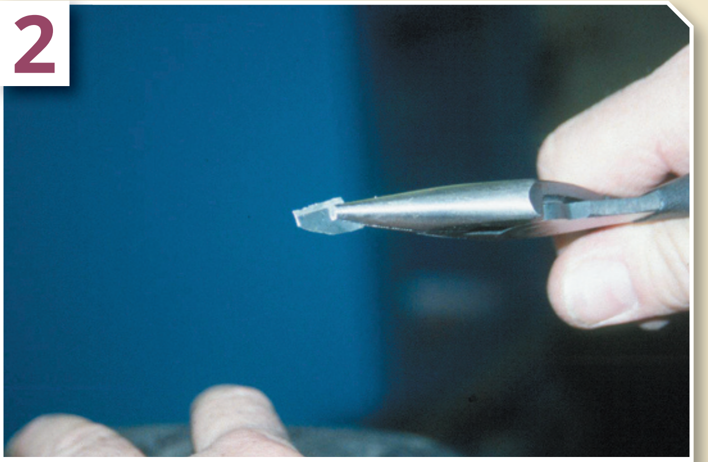
TIRE REPAIR

1



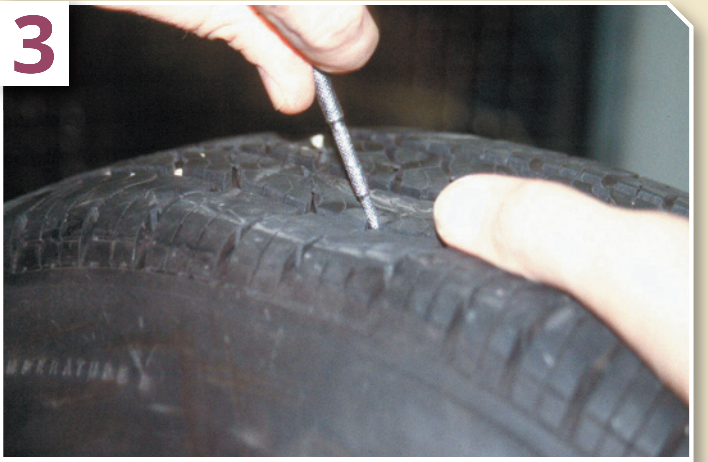
The source of the leak was detected by spraying soapy water on the inflated tire. Needle-nose pliers are being used to remove the object that caused the flat tire.

2



A part of a razor blade was found to be the cause of the flat tire.

3



A reamer is being used to clean the puncture hole.

4

REVIEW QUESTIONS

1. What are the precautions and recommendations regarding tire maintenance?
2. What are the most commonly used tire rotation methods?
3. How are lateral and radial runout of wheels and tires checked?
4. What is the difference between static and dynamic balance?
5. Why is a pin plate used on some wheels when attaching it to a balancer?

CHAPTER QUIZ

1. Proper tire inflation pressure information is found ___________.
   a. on the driver's door or post
   b. under the hood on the VECI sticker
   c. on the sidewall of the tire
   d. Both a and b
2. A tire is worn excessively on both edges. The most likely cause of this type of tire wear is ___________.
   a. overinflation
   b. underinflation
   c. excessive radial runout
   d. excessive lateral runout
3. Lug nuts should be evenly tightened in a(n) ___________ pattern.
   a. linear
   b. star
   c. opposing
   d. random
4. Tire replacement involves all of the following except ___________.
   a. remove the air from the tire
   b. remove the TPMS sensor from the wheel
   c. remove the tire from the rim (wheel)
   d. install the tire on the rim (wheel)
5. Using the modified X method of tire rotation on a front-wheel-drive vehicle, where should the left front wheel be placed?
   a. Right front
   b. Right rear
   c. Left rear
   d. Left front
6. Which statement is *false*?
   a. Excessive radial runout can cause a tramp-type vibration.
   b. Excessive lateral runout can cause a tramp-type vibration.
   c. A tire out of balance dynamically can cause a shimmy-type vibration.
   d. A tire out of balance statically can cause a tramp-type vibration.
7. When seating a bead of a tire, never exceed ___________ PSI.
   a. 30
   b. 40
   c. 50
   d. 60
8. When balancing a tire/wheel assembly, what should the technician do?
   a. Use the proper contour wheel weights.
   b. Set up the tire balancer machine with the location of the wheel as well as the diameter and width.
   c. Clean the rim flange.
   d. All of the above
9. A vehicle vibrates at highway speed. Technician A says that water in the tire(s) could be the cause. Technician B says that an out-of-round tire could be the cause. Which technician is correct?
   a. Technician A only
   b. Technician B only
   c. Both Technicians A and B
   d. Neither Technician A nor B
10. A tire has a nail in the shoulder area. What should the technician do?
    a. Replace the tire.
    b. Repair the tire with a double patch.
    c. Repair the tire with a rubber plug.
    d. Install an inner tube.

FRAME CONSTRUCTION

TERMINOLOGY Frame construction usually consists of channel-shaped steel beams welded and/or fastened together. The frame of a vehicle supports all the "running gear" of the vehicle, including the engine, transmission, rear axle assembly (if rear-wheel drive), and all suspension components.

This frame construction, referred to as **full frame**, is so complete that most vehicles can usually be driven without the body. Most trucks and larger rear-wheel-drive cars use a full frame.

LADDER FRAME A **ladder frame** is a common name for a type of perimeter frame where the transverse (lateral) connecting members are straight across. ● **SEE FIGURE 111–1**. When viewed with the body removed, the frame resembles a ladder. Most pickup trucks are constructed with a ladder-type frame.

PERIMETER FRAME A **perimeter frame** consists of welded or riveted frame members around the entire perimeter of the body. This means that the frame members provide support underneath the sides as well as for the suspension and suspension components. ● **SEE FIGURE 111–2.**

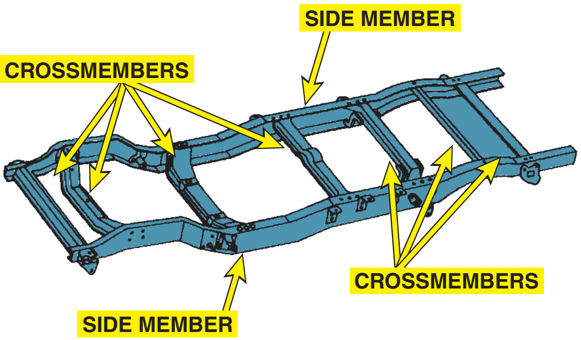

FIGURE 111–1 A typical truck frame is an excellent example of a ladder-type frame. The two side members are connected by crossmembers.

STUB-TYPE FRAMES A **stub-type frame** is a partial frame often used on unit-body vehicles to support the power train and suspension components. It is also called a **cradle** on many front-wheel-drive vehicles. ● **SEE FIGURE 111–3**.

UNIT-BODY CONSTRUCTION **Unit-body** construction (sometimes called *unibody*) is a design that combines the body with

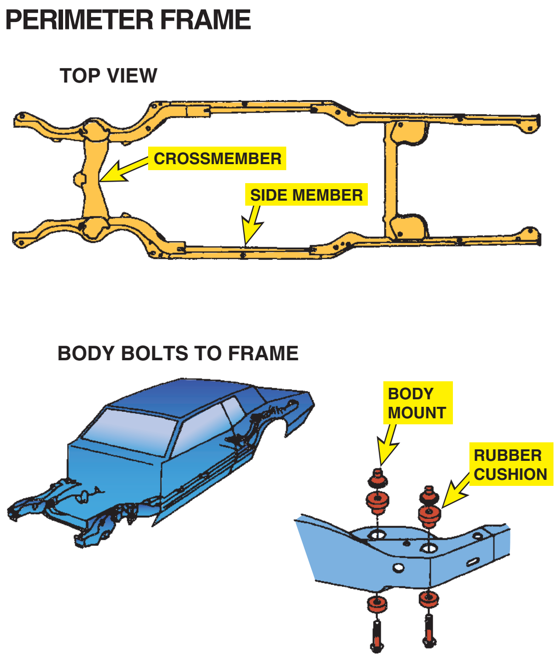

FIGURE 111–2 Rubber cushions used in Body-On-Frame (BOF) construction isolate noise and vibration from traveling to the passenger compartment.

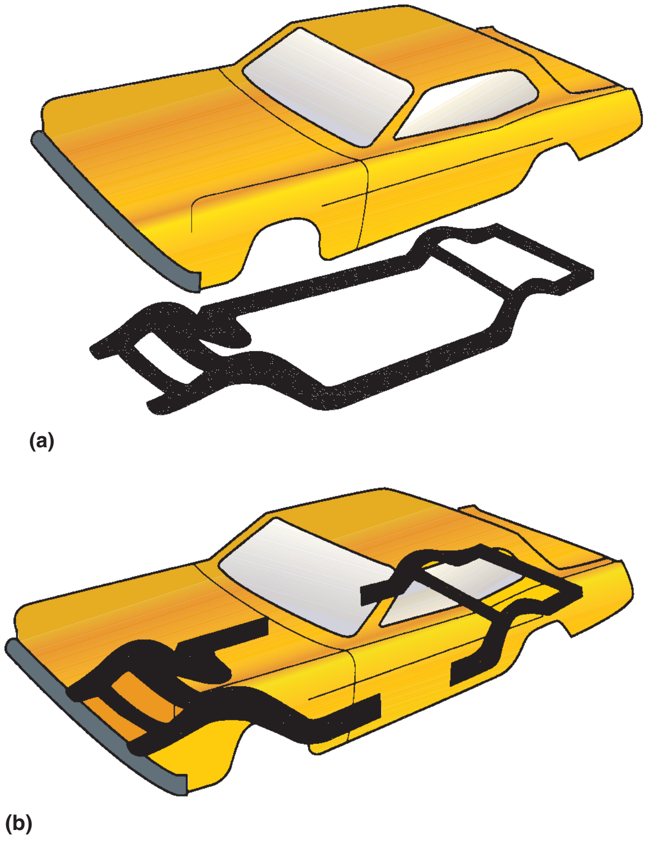

FIGURE 111–3 (a) Separate body and frame construction; (b) stub-type frame: the small frame members are for support of the engine and suspension components. Many vehicles attach the suspension components directly to the reinforced sections of the body and do not require the rear frame section.

the structure of the frame. The body supports the engine and driveline components, as well as the suspension and steering components. The body is composed of many individual stamped-steel panels welded together.

FREQUENTLY ASKED QUESTION

What Does GVW Mean?

GVW, gross vehicle weight, is the weight of the vehicle plus the weight of all passengers the vehicle is designed to carry (× 150 lb [68 kg] each), plus the maximum allowable payload or luggage load. *Curb weight* is the weight of a vehicle when *wet*, meaning with a full tank of fuel and all fluids filled, but without passengers or cargo (luggage). *Model weight* is the weight of a vehicle wet and with passengers.

The GVW is found stamped on a plate fastened to the door jamb of most vehicles. A high GVW rating does not mean that the vehicle itself weighs a lot more than other vehicles. For example, a light truck with a GVW of 6,000 lbs (2,700 kg) will not ride like an old 6,000 pound luxury car. In fact, a high GVW rating usually requires stiff springs to support the payload; these stiff springs result in a harsh ride. Often technicians are asked to correct a harsh-riding truck that has a high GVW rating. The technician can only check that everything in the suspension is satisfactory and then try to convince the owner that a harsher-than-normal ride is the result of a higher GVW rating.

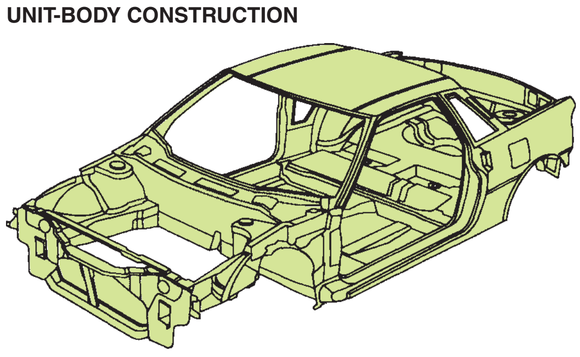

FIGURE 111–4 Welded metal sections create a platform that combines the body with the frame using unit-body construction.

The strength of this type of construction lies in the *shape* of the assembly. The typical vehicle uses 300 separate and different stamped-steel panels that are spot-welded to form a vehicle's body. ● **SEE FIGURE 111–4**.

NOTE: A typical vehicle contains about 10,000 individual parts.

SPACE FRAME CONSTRUCTION **Space frame** construction consists of formed sheet steel used to construct a framework for the entire vehicle. The vehicle is drivable without the body, which uses plastic or steel panels to cover the steel framework.

PLATFORMS

TERMINOLOGY The **platform** of any vehicle is its basic size and shape. Various vehicles of different makes can share the same platform, and therefore many of the same drivetrain (engine, transmission, and final drive components) and suspension and steering components.

A platform of a unit-body vehicle includes all major sheet-metal components that form the load-bearing structure of the vehicle, including the front suspension and engine-supporting sections. The area separating the engine compartment from the passenger compartment is called the **bulkhead**. The height and location of this bulkhead panel to a large degree determines the shape of the rest of the vehicle.

Other components of vehicle platform design that affect handling and ride are the track and wheelbase of the vehicle. *The track of a vehicle is the distance between the wheels, as viewed from the front or rear.* A wide-track vehicle is a vehicle with a wide wheel stance; this increases the stability of the vehicle, especially when cornering. *The wheelbase of a vehicle is the distance between the center of the front wheel and the center of the rear wheel, as viewed from the side.* A vehicle with a long wheelbase tends to ride smoother than a vehicle with a short one.

Examples of common platforms include the following:

1. Chevrolet Impala and Cadillac XTS
2. Toyota Camry and Lexus ES 350
3. Honda CRV and Acura RDX

TYPES OF SUSPENSIONS

Early suspension systems on old horse wagons, buggies, and older vehicles used a solid axle for front and rear wheels. ● **SEE FIGURE 111–5**. If one wheel hit a bump, the other wheel was affected, as shown in ● **FIGURE 111–6**.

Most vehicles today use a separate control-arm-type of suspension for each front wheel, which allows for movement of one front wheel without affecting the other front wheel. This type of front suspension is called **independent suspension**. ● **SEE FIGURE 111–7**.

Many rear suspensions also use independent-type suspension systems. Regardless of the design type of suspension, all suspensions use springs in one form or another.

SPRINGS A suspension **spring** serves two purposes. First, it acts as a buffer between the suspension and frame to absorb vertical wheel and suspension movement without passing it on to the frame. Second, each spring transfers part of the vehicle weight to the suspension component it rests on, which transfers it to the wheels.

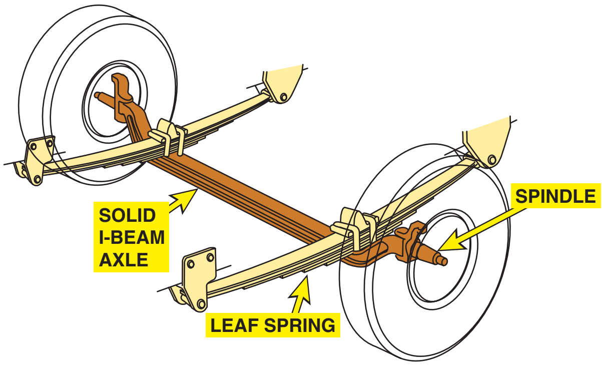

FIGURE 111–5 Solid I-beam axle with leaf springs.

The basic method by which springs absorb road shocks varies according to the type of spring. Simply stated, leaf springs flatten, coil springs and air springs compress, and torsion bars twist. What all springs have in common is that they somehow give way to absorb the vertical force of the moving wheel during jounce, then release that force during rebound as they return to their original shape and position.

SPRING MATERIALS Most springs are made of a tempered steel alloy known as spring steel, usually chrome silicon or chrome vanadium alloy. Tempering is a process of heating and cooling metal under controlled conditions, which increase the resilience of the metal. Resilience is the ability of the metal to return to, or spring back to, its original shape after being twisted or compressed.

HOOKE'S LAW

DEFINITION Regardless of type, all suspensions use springs that share a common characteristic described by **Hooke's law**. Robert Hooke (1635–1703), an English physicist, discovered the

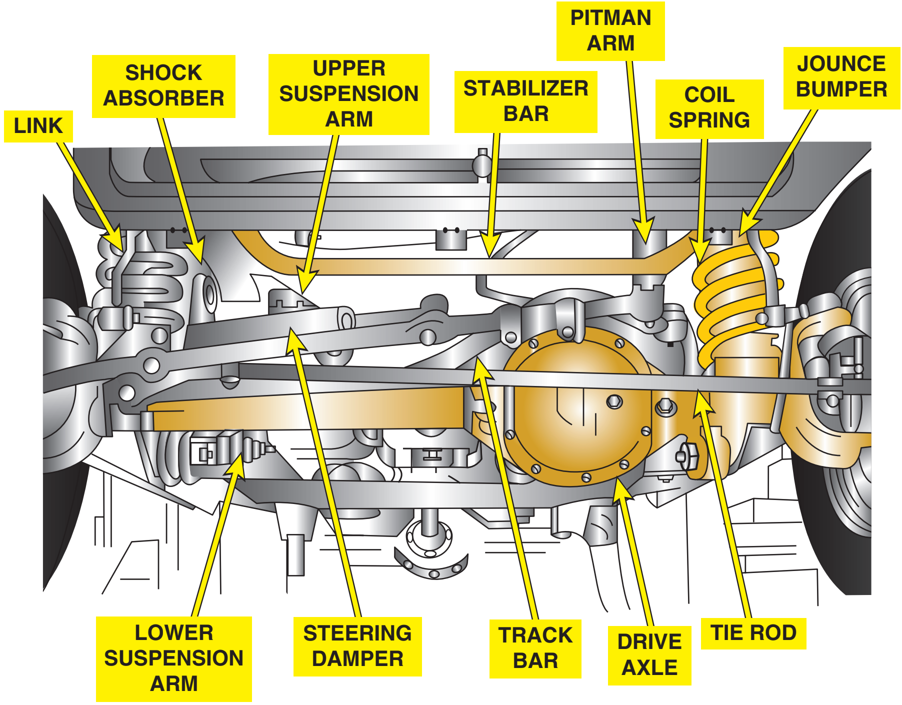

FIGURE 111–6 The front drive axle on a Jeep is a type of solid axle. When one wheel hits a bump or drops into a hole, both left and right wheels are moved. Because both wheels are affected, the ride is often harsh and feels stiff.

FIGURE 111–8 This spring was depressed 4 inches due to a weight of 2,000 pounds. This means that this spring has a spring rate (*K*) of 500 pounds per inch (2,000 ÷ 4 in. = 500 lb./ in.).

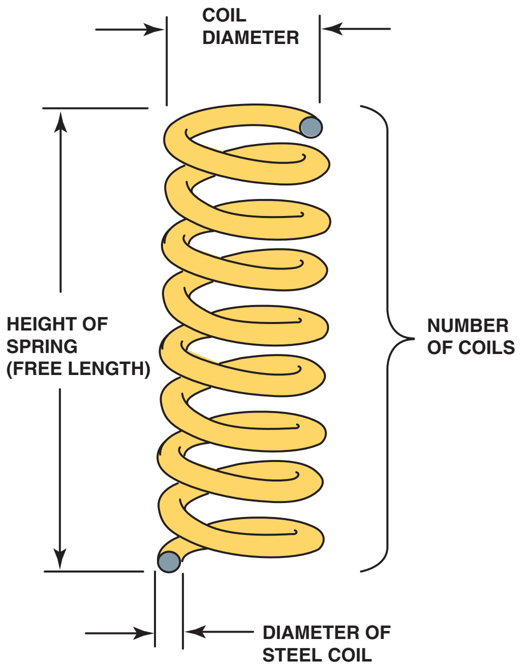
force characteristics of springs: *The deflection (movement or deformation) of a spring is directly proportional to the applied force.*

What this means is that when a coil spring, for example, is depressed 1 inch, it pushes back with a certain force (in pounds), such as 400 pounds. If the spring is depressed another inch, the force exerted by the spring is increased by another 400 pounds. The **spring rate** or force constant for this spring is therefore “400 pounds per inch,” usually symbolized by the letter K. Since the force constant is the force per unit of displacement (movement), it is a measure of the stiffness of the spring. The higher the spring rate (*K*), the stiffer the spring. ● **SEE FIGURE 111–8**.

COIL SPRINGS

TERMINOLOGY **Coil springs** are made of special round spring steel wrapped in a helix shape. The strength and handling characteristics of a coil spring depend on the following:

1. Coil diameter
2. Number of coils
3. Height of spring
4. Diameter of the steel coil that forms the spring. ● **SEE FIGURE 111–9**.



COIL DIAMETER
HEIGHT OF SPRING (FREE LENGTH)
NUMBER OF COILS
DIAMETER OF STEEL COIL

FIGURE 111–9 The spring rate of a coil spring is determined by the diameter of the spring and the diameter of the steel used in its construction, plus the number of coils and the free length (height).

The spring rate (*K*) for coil springs is expressed by the formula:

$$K = \frac{Gd4}{8ND3}$$

where

G = **11,250,000 (constant for steel)**

d = **diameter of wire**

N = **number of coils**

D = **diameter of the coil**

Coil springs are used in front and/or rear suspensions.

The larger the diameter of the steel, the “stiffer” the spring.

The shorter the height of the spring, the stiffer the spring.

The fewer the coils, the stiffer the spring.

Springs are designed to provide desired ride and handling and come in a variety of spring ends, as shown in ● **FIGURE 111–10**.

FIGURE 111–10 Coil spring ends are shaped to fit the needs of a variety of suspension designs.

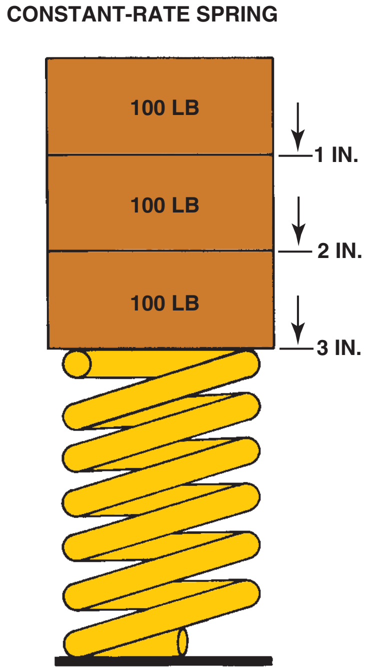

FIGURE 111–11 A constant-rate spring compresses at the same rate regardless of the amount of weight that is applied.

CAUTION: The use of spacers between the coils of a coil spring is *not* recommended because the force exerted by the spacers on the springs can cause spring breakage. When a spacer is installed between the coils, the number of coils is reduced and the spring becomes stiffer. The force exerted on the coil spring at the contact points of the spacer can cause the spring to break.

SPRING RATE Spring rate, also called *deflection rate*, is a value that reflects how much weight it takes to compress a spring a certain amount. Generally, spring rate is specified in pounds per inch, which is the weight in pounds it takes to compress the spring 1 inch. In other words, if a 100 pound weight causes a spring to compress 1 inch, the spring has a spring rate of 100 pounds.

A constant-rate spring continues to compress at the same rate throughout its complete range of deflection. For example, if a constant-rate spring compresses 1 inch under a 100 pound load, it will compress 2 inches under a 200 pound load, and so on. ● **SEE FIGURE 111–11.** Many automotive suspension springs, both coil and leaf, compress at a variable rate. That is, they become stiffer and exert more force the farther they compress. For example, a variable-rate spring may compress 1 inch under a 100 pound load, but only compress an additional 1/2 inch under a 200 pound load. Variable-rate springs offer a soft, comfortable ride under normal circumstances but will not bottom out as quickly when adverse road conditions compress them farther. ● **SEE FIGURE 111–12.**

Before a spring is installed on a vehicle or any load is placed on it, it is at its uncompressed length, or free length. Once installed, the weight of the corner of the vehicle resting on the spring is called its *static load*. The static load constantly compresses the spring. Therefore, the uncompressed length and the spring rate must be such that the spring has room to compress and keep the vehicle at the correct ride height *after* the static load is applied. ● **SEE FIGURE 111–13.**

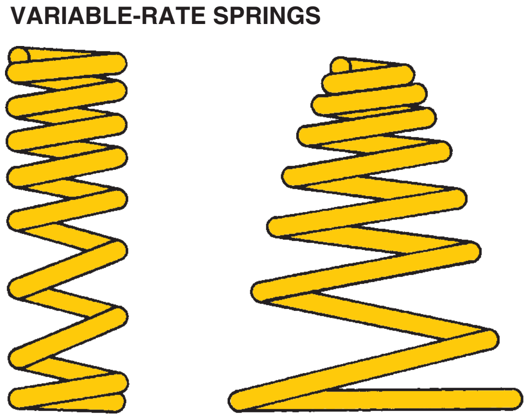

FIGURE 111–12 Variable-rate springs come in a variety of shapes and compress more slowly as weight is applied.

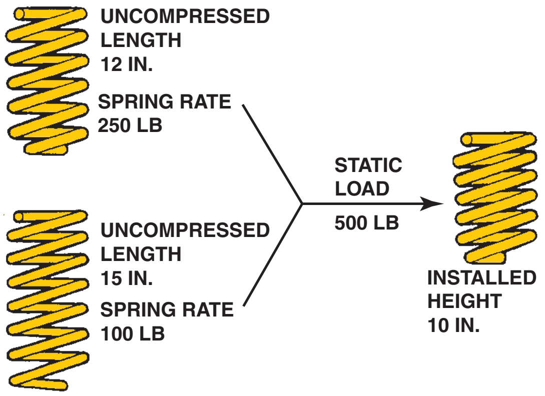

FIGURE 111–13 Two springs, each with a different spring rate and length, can provide the same ride height even though the higher rate spring will give a stiffer ride.

FREQUENTLY ASKED QUESTION

Does the Spring Rate Change as the Vehicle Gets Older?

No, the spring rate of a spring does not change, but the spring load can change due to fatigue. The spring rate is the amount of force it takes to compress the spring 1 inch. The spring load is the amount of weight that a spring can support at any given compressed height. When a spring fatigues, the spring's load capacity decreases and the vehicle will sag.

Typical Front-Wheel-Drive Sedan Springs

	Force @ Height	Spring Rate
LF	1,343 lb @ 7.6 in.	256 lb in.
RF	1,300 lb @ 7.6 in.	254 lb in.
LR	638 lb @ 9.38 in.	200 lb in.
RR	610 lb @ 9.38 in.	195 lb in.

Notice that each of the four coil springs used on this vehicle is unique. The higher spring rate on the left is used to help support the weight of the driver. Because each spring is designed for each location on the vehicle, they should be marked if they are removed from a vehicle during service.

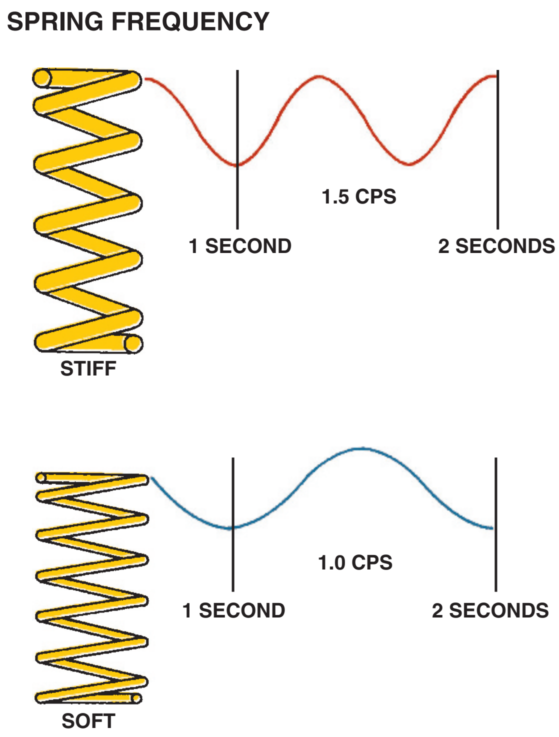

FIGURE 111–14 Stiffer springs bounce at a higher frequency than softer springs.

SPRING FREQUENCY Spring frequency is a value that reflects the speed at which a spring oscillates, or bounces, after it is released from compression or extension. Frequency is typically measured in cycles per second (CPS) or hertz (Hz). ● **SEE FIGURE 111–14**. There is a direct correlation between spring rate and spring frequency: the higher the spring rate, the higher the spring frequency. This means that stiffer springs bounce at a higher frequency, while softer springs bounce more slowly.

WHEEL RATE Depending on the suspension design, springs are installed a certain distance away from the wheel, which determines the ratio of wheel travel to spring travel, or **wheel rate**. ● **SEE FIGURE 111–15**. For example, if a coil spring is mounted on the midpoint of a control arm, or halfway between the center of the wheel and the arm pivot points, it compresses approximately 1 inch when the wheel travels vertically 2 inches. On a strut-type suspension, the coil spring has a more direct ratio because it is closer to the wheel, so when the wheel of a strut travels vertically 2 inches, the spring also compresses 2 inches. This means that a coil spring used on a strut-type suspension is less than half the spring rate of a coil spring used on suspensions that use control arms.

COIL SPRING MOUNTING Coil springs are usually installed in a **spring pocket** or spring seat. Hard rubber or plastic cushions or **insulators** are usually mounted between the coil spring and the spring seat. ● **SEE FIGURE 111–16**. The purpose of these insulators is to isolate and dampen road noise and vibration from the vehicle body. The type of end on the coil spring also varies and determines the style of the spring mount.

SPRING COATINGS All springs are painted or coated with epoxy to help prevent breakage. A scratch, nick, or pit caused by corrosion can cause a **stress riser** that can lead to spring failure. The service technician should be careful not to remove any of the protective coating. Whenever a service operation requires the spring to be compressed, always use a tool that will not scratch or nick the surface of the spring.

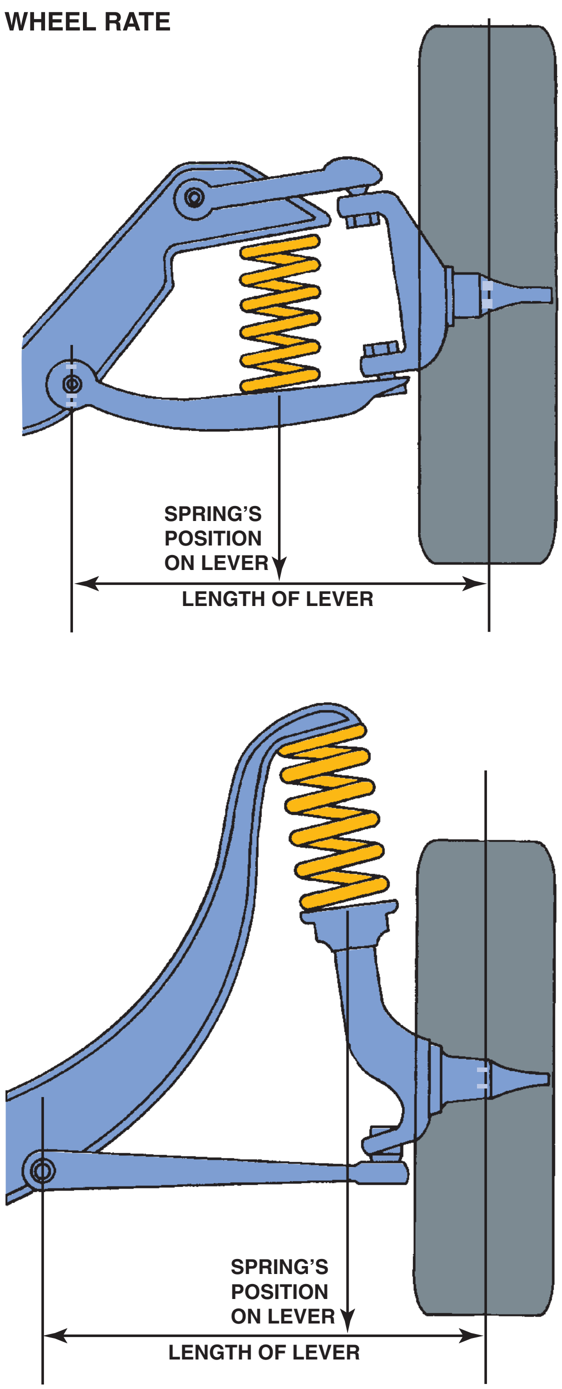

FIGURE 111–15 The wheel and arm act as a lever to compress the spring. The spring used on the top picture must be stiffer than the spring used on the strut-type suspension shown on the bottom because the length of the lever arm is shorter.

LEAF SPRINGS

TERMINOLOGY **Leaf springs** are constructed of one or more strips of long, narrow spring steel. These metal strips, called leaves, are assembled with plastic or synthetic rubber insulators

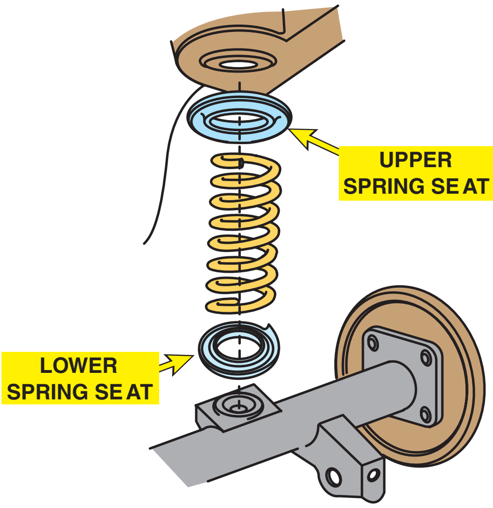

FIGURE 111–16 The spring cushion helps isolate noise and vibration from being transferred to the passenger compartment.

TECH TIP

Don't Cut Those Coil Springs!

Chassis service technicians are often asked to lower a vehicle. One method is to remove the coil springs and cut off half or more coils from the spring. While this *will* lower the vehicle, this method is generally *not* recommended for the following reasons:

1. A coil spring could be damaged during the cutting-off procedure, especially if a torch is used to do the cutting.
2. The spring will get stiffer when shortened, often resulting in a very harsh ride.
3. The amount the vehicle is lowered is *less* than the amount cut off from the spring. This is because as the spring is shortened, it becomes stiffer. The stiffer spring will compress less than the original.

Instead of cutting springs to lower a vehicle, several preferable methods are available if the vehicle *must* be lowered:

1. There are replacement springs designed specifically to lower that model vehicle. A change in shock absorbers may be necessary because the shorter springs change the operating height of the stock (original) shock absorbers. Consult spring manufacturers for exact installation instructions and recommendations. ● **SEE FIGURE 111–17**.
2. There are replacement spindles designed to *raise* the location of the wheel spindle, thereby lowering the body in relation to the ground. Except for ground clearance problems, this is the method recommended by many chassis service technicians. Replacement spindles keep the same springs, shock absorbers, and ride, while lowering the vehicle without serious problems.

FIGURE 111–17 This replacement coil spring is coated to prevent rust and corrosion and colored to help identify the spring and/or spring manufacturer.

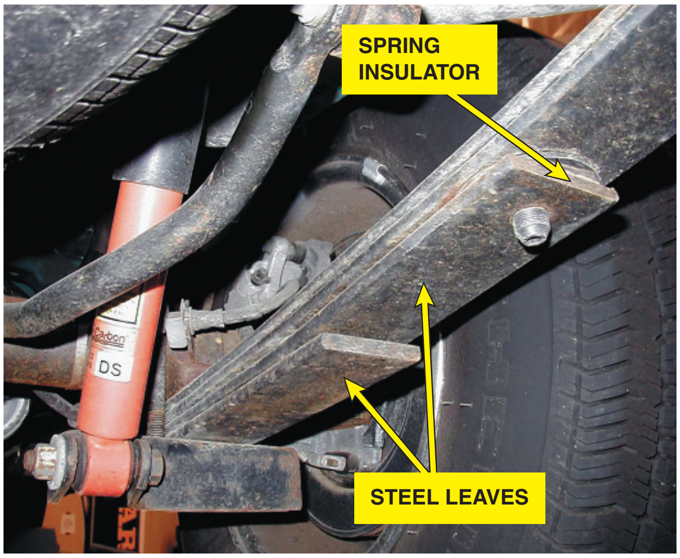

FIGURE 111–18 A typical leaf spring used on the rear of a pickup truck showing the plastic insulator between the leaves, which allows the spring to move without creating wear or noise.

between the leaves, allowing for freedom of movement during spring operation. ● **SEE FIGURE 111–18**.

The ends of the spring are rolled or looped to form eyes. Rubber bushings are installed in the eyes of the spring and act as noise and vibration insulators. Leaf spring rate increases when the thickness increases and decreases as the length increases. ● **SEE FIGURE 111–19**.

The leaves are held together by a **center bolt**, also called a *centering pin*. ● **SEE FIGURE 111–20**.

One end of a leaf spring is mounted to a hanger with a bolt and rubber bushings directly attached to the frame. The other end of the leaf spring is attached to the frame with movable mounting hangers called **shackles**. ● **SEE FIGURE 111–21**.

The shackles are necessary because as the spring hits a bump, the slightly curved spring (semi-elliptical) becomes longer and straighter, and the shackles allow for this rearward movement. **Rebound clips**, or spring alignment clips, help prevent the leaves from separating whenever the leaf spring is rebounding from hitting a bump or rise in the roadway. ● **SEE FIGURE 111–22**.

Single-leaf steel springs, called **mono leaf**, are used on some vehicles. A single or mono leaf spring is usually tapered

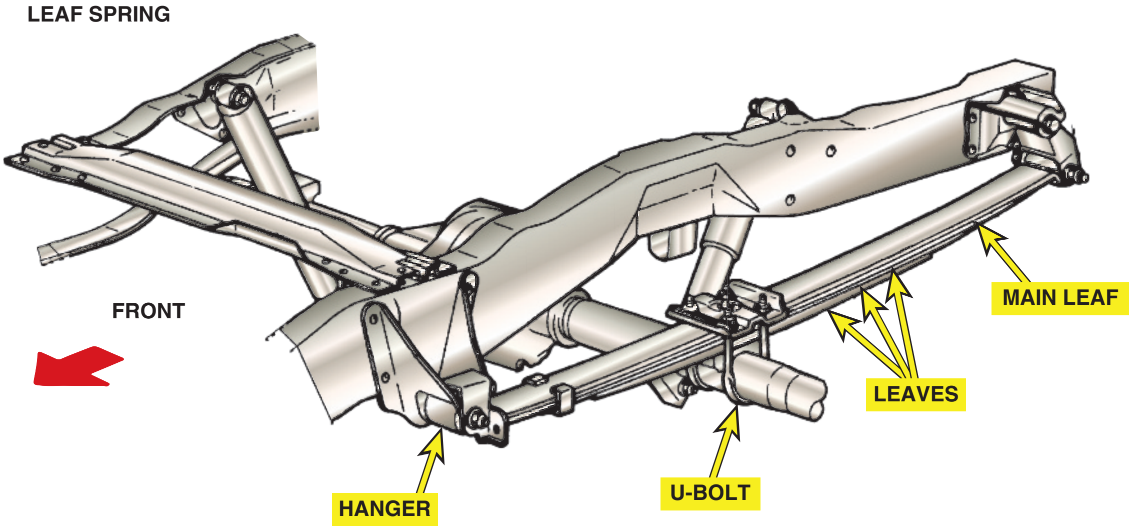

FIGURE 111–19 A typical leaf spring installation. The longest leaf, called the *main leaf*, attaches to the frame through a shackle and a hanger.

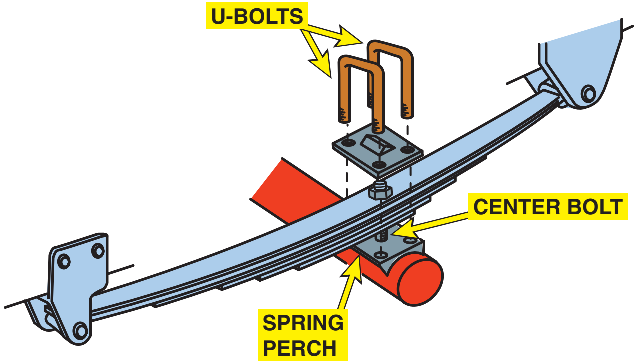

FIGURE 111–20 All multileaf springs use a center bolt to not only hold the leaves together but also help retain the leaf spring in the center of the spring perch.

to produce a variable spring rate. Leaf springs are used for rear suspensions on cars and many light trucks. A variable rate can be accomplished with a leaf-spring suspension by providing contacts on the mount that effectively shorten the spring once it is compressed to a certain point. This provides a smoother ride when the load is light and still provides a stiffer spring when the load is heavy. ● **SEE FIGURE 111–23**.

To provide additional load-carrying capacity, especially on trucks and vans, auxiliary or *helper* leaves are commonly used. This extra leaf becomes effective only when the vehicle is heavily loaded. ● **SEE FIGURE 111–24**.

Leaf springs are used on the front suspension of many four-wheel-drive trucks, especially medium and heavy trucks.

COMPOSITE LEAF SPRINGS Since the early 1980s, fiberglass–reinforced epoxy plastic **composite leaf springs** have been used on production vehicles. They save weight: an 8 pound spring can replace a conventional 40 pound steel leaf spring. The secret to making a strong plastic leaf spring is the glass fibers running continuously from one end of the spring to the other and the use of 70% fiberglass with 30% epoxy composite. The single-leaf composite spring helps isolate road noise and vibrations. It is more efficient than a multileaf spring because it eliminates the interleaf friction of the steel leaves and requires less space. ● **SEE FIGURE 111–25**.

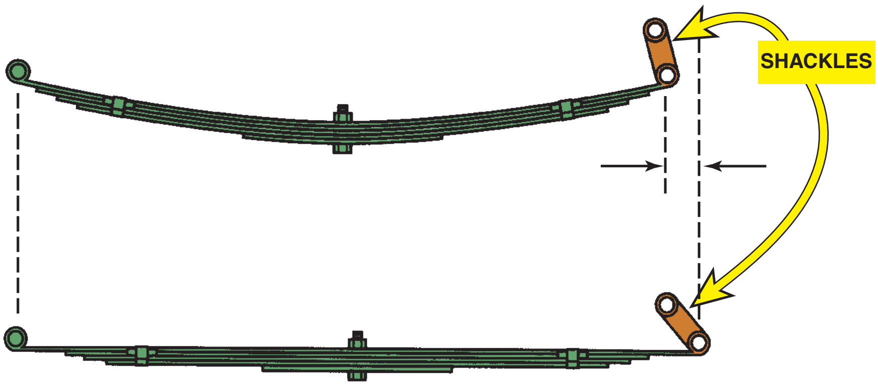

FIGURE 111–21 When a leaf spring is compressed, the spring flattens and becomes longer. The shackles allow for this lengthening. Rubber bushings are used in the ends of the spring and shackles to help isolate road noise from traveling into the passenger compartment.

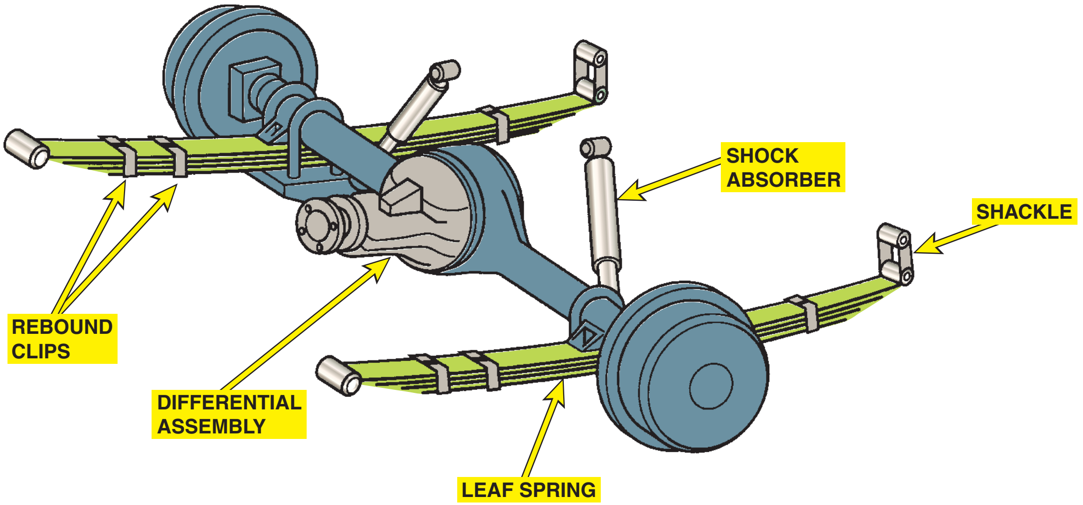

FIGURE 111–22 Typical rear leaf—spring suspension of a rear-wheel-drive vehicle.

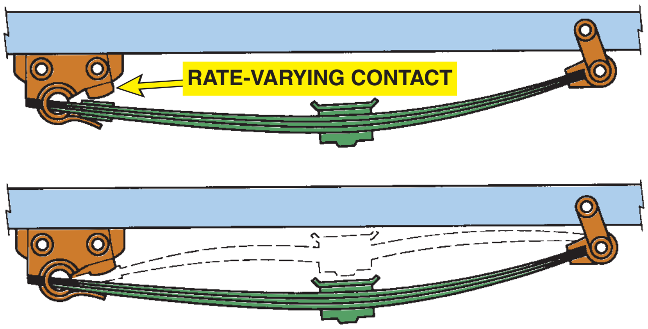

FIGURE 111–23 As the vehicle is loaded, the leaf spring contacts a section of the frame. This shortens the effective length of the spring, which makes it stiffer.

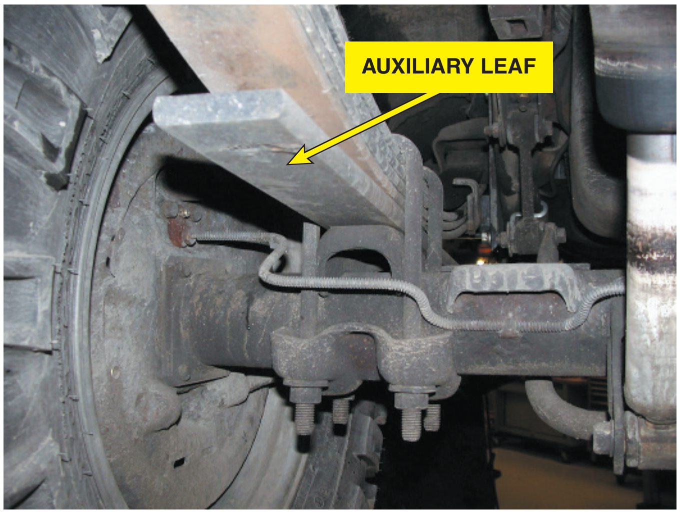

FIGURE 111–24 Many pickup trucks, vans, and sport-utility vehicles (SUVs) use auxiliary leaf springs that contact the other leaves when the load is increased.

TORSION BARS

TERMINOLOGY A **torsion bar** is a spring that is a long, *round,* hardened steel bar similar to a coil spring except that it is a *straight* bar. ● **SEE FIGURE 111–26.** One end is attached to the lower control arm of a front suspension and the other end to the frame. When the wheels hit a bump, the bar twists and then untwists. General Motors pickup trucks use torsion-bar front suspension longitudinally. ● **SEE FIGURE 111–27.**

Many manufacturers of pickup trucks currently use torsion-bar-type suspensions, especially on their four-wheel-drive models. Torsion bars allow room for the front drive axle and constant velocity joint and still provide for strong suspension.

As with all automotive springs, spring action is controlled by the shock absorbers. Unlike other types of springs, torsion bars may be adjustable for correct ride height. ● **SEE FIGURE 111–28.**

Most torsion bars are labeled *left* or *right,* usually stamped into the end of the bars. The purpose of this designation is to make sure that the correct bar is installed on the original side of the vehicle. Torsion bars are manufactured without any built-in direction or preload. However, after being in a vehicle, the bar takes a set; reversing the side the torsion bar is used on causes the bar to be twisted in the opposite direction. Even though the bars are usually interchangeable, proper ride height can be accomplished even if the bars were installed on the side opposite from the original. But because the bar is being "worked" in the opposite direction, it can weaken and break. If a torsion bar breaks, the entire suspension collapses; this can cause severe vehicle damage, as well as a serious accident.

SUSPENSION PRINCIPLES AND COMPONENTS

Suspensions use various links, arms, and joints to allow the wheels to move freely up and down; front suspensions also have to allow the front wheels to turn. All suspensions must provide for the following supports:

1. **Transverse (or side-to-side) wheel support.** As the wheels of the vehicle move up and down, the suspension must accommodate this movement and still keep the wheel from moving away from the vehicle or inward toward the center

FIGURE 111–25 (a) A fiberglass spring is composed of long fibers locked together in an epoxy (resin) matrix. (b) When the spring compresses, the bottom of the spring expands and the top compresses. Composite leaf springs are used and mounted transversely (side to side) on Chevrolet Corvettes and at the rear on some other General Motors vehicles.

FIGURE 111–26 A torsion bar resists twisting and is used as a spring on some cars and many four-wheel-drive pickup trucks and sport-utility vehicles. The larger the diameter, or the shorter the torsion bar, the stiffer the bar. A torsion bar twists very little during normal operation and about a 1/16 of a revolution during a major suspension travel event.

of the vehicle. ● **SEE FIGURE 111–29**. The control arm pivots on the vehicle frame. The wheels attach to a spindle that attaches to the ball joint at the end of the control arm. Transverse links are also called **lateral links**.

2. **Longitudinal (front-to-back) wheel support.** As the wheels of the vehicle move up and down, the suspension must allow for this movement and still keep the wheels from moving backward whenever a bump is hit. Note in ● **FIGURE 111–29** how the separation of the pivot points, where the control arm meets the frame, provides support to prevent front-to-back wheel movement.

At least two suspension links or arms are required in order to provide for freedom of movement up or down and to *prevent* any in-out or forward-back movement. Some suspension designs use an additional member to control forward-back movement. ● **SEE FIGURE 111–30**.

The design of the suspension and the location of the suspension mounting points on the frame or body are critical to proper vehicle handling. Two very important design factors are called **anti-squat** and **anti-dive**.

FIGURE 111–30 The strut rods provide longitudinal support to the suspension to prevent forward or rearward movement of the control arms.

1. **Anti-squat.** Anti-squat refers to the reaction of the body of a vehicle during acceleration. It is normal in most designs for the vehicle to squat down at the rear while accelerating. Most drivers feel comfortable feeling this reaction, even on front-wheel-drive vehicles. Anti-squat refers to the degree to which this normal force is neutralized. If 100% anti-squat were designed into the suspension system, the vehicle would remain level while accelerating.
2. **Anti-dive.** Anti-dive refers to the force that causes the front of the vehicle to drop down while braking. Some front-nose dive feels normal to most drivers. If 100% anti-dive were designed into a vehicle, it would remain perfectly level while braking.

The service technician cannot, and should not, attempt to change anti-squat or anti-dive characteristics built into the design of the vehicle. However, if the customer notices more squat or dive than normal, then the technician should carefully inspect all suspension components, especially those mounting points to the frame or body.

STEERING KNUCKLES

Steering knuckle is hard to classify either as part of the suspension or as part of the wheel. A knuckle serves two purposes:

- To join the suspension to the wheel
- Usually includes the spindle where the front wheel bearings are attached
- To provide pivot points between the suspension and wheel

Knuckles are used with independent suspensions and at the wheels that steer the vehicle. ● **SEE FIGURE 111–31**.

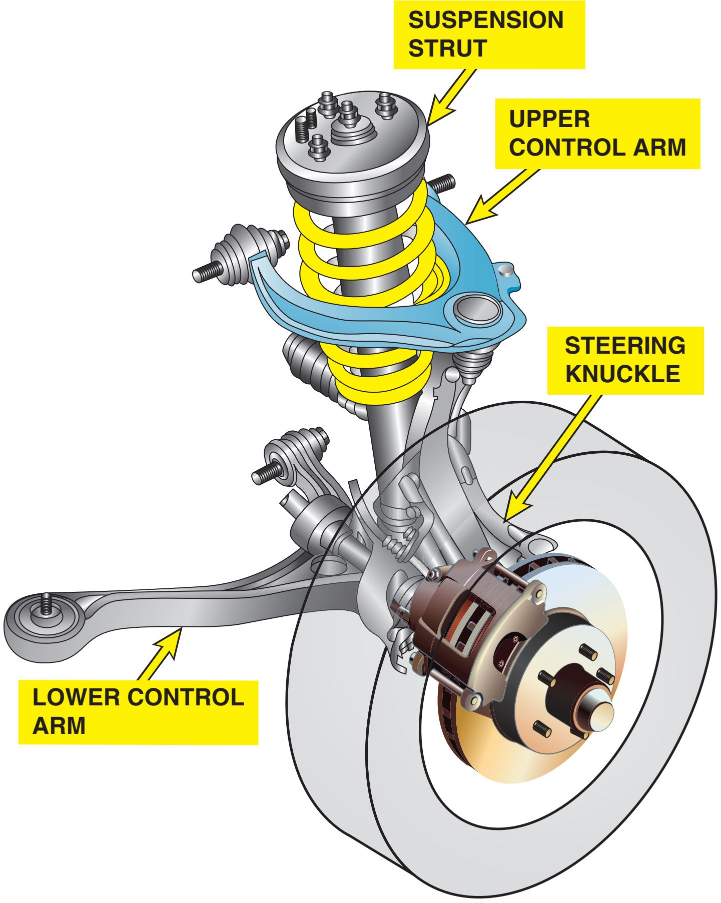

FIGURE 111–31 The steering knuckle used on a short-/long-arm front suspension.

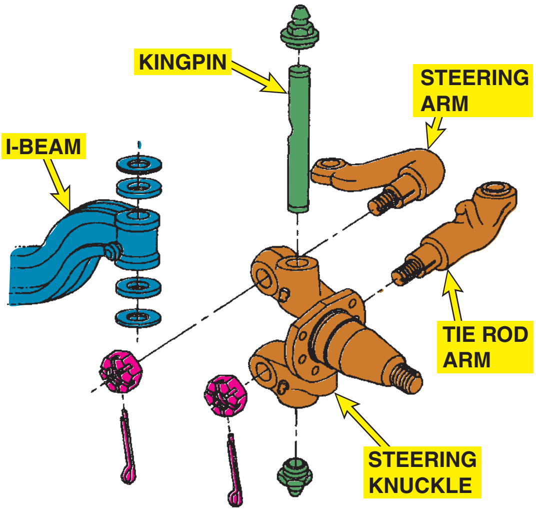

FIGURE 111–32 A kingpin is a steel shaft or pin that joins the steering knuckle to the suspension and allows the steering knuckle to pivot.

The only knuckle that uses a **kingpin** is a steering knuckle on an I-beam or twin I-beam front suspension. ● **SEE FIGURE 111–32**. A kingpin steering knuckle keeps the wheel rigid in relation to the I-beam during up-and-down wheel movement, but rotates around the steering axis to turn the wheels left and right. The steering axis is the vertical center of the kingpin.

CONTROL ARMS

Control arm is a suspension link that connects a knuckle or wheel flange to the frame. One end of a control arm attaches to the knuckle or wheel flange, generally with either a ball joint or bushing. The opposite end of the arm, which attaches to a frame member, usually pivots on a bushing. ● **SEE FIGURE 111–33**. The end attached to the frame must pivot to allow the axle or knuckle to travel vertically.

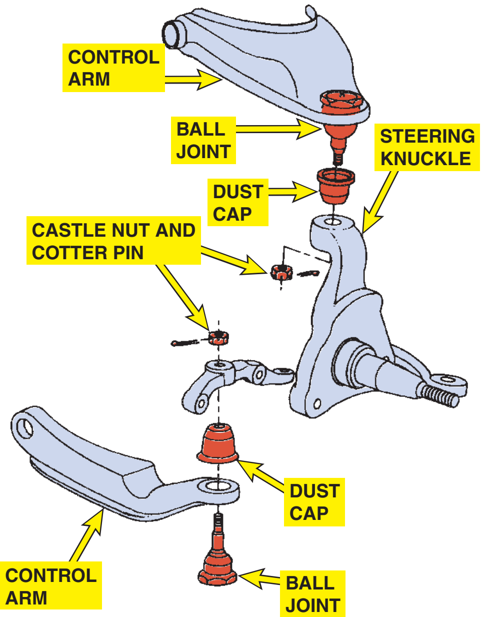

FIGURE 111–33 Control arms are used to connect the steering knuckle to the frame or body of the vehicle and provide the structural support for the suspension system.

FIGURE 111–34 Ball joints provide the freedom of movement necessary for steering and suspension movements.

BALL JOINTS **Ball joints** are actually ball-and-socket joints, similar to the joints in a person's shoulder. Ball joints allow the front wheels to move up and down, as well as side to side (for steering).

A vehicle can be equipped with coil springs, mounted either above the upper control arm *or* on the lower control arm. ● **SEE FIGURE 111–34**.

If the coil spring is attached to the top of the upper control arm, then the upper ball joint is carrying the weight of the vehicle and is called the **load-carrying ball joint**. The lower ball joint is called the **non-load-carrying**, or *follower*, ball joint. ● **SEE FIGURE 111–35**.

If the coil spring is attached to the lower control arm, then the lower ball joint is the load-carrying ball joint and the upper joint is the follower ball joint. ● **SEE FIGURE 111–36**.

If a torsion-bar-type spring is used, the lower ball joint is a load-carrying joint because the torsion bar is attached to the lower control arm on most vehicles that use torsion bars.

BALL JOINT DESIGN There are two basic designs of ball joints: compression loaded and tension loaded. If the control arm rests on the steering knuckle, the ball joint is *compressed* into the control arm by the weight of the vehicle. If the knuckle rests on the control arm, the weight of the vehicle tends to pull the ball joint

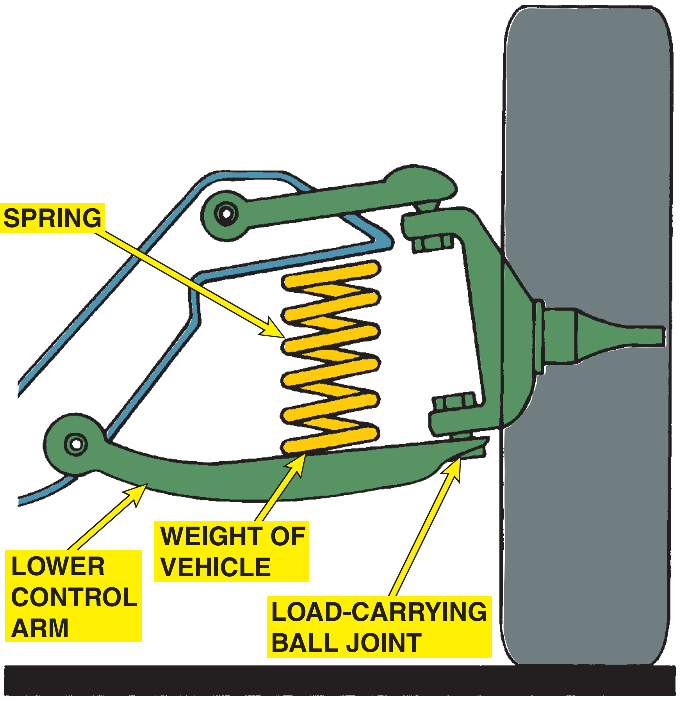

FIGURE 111–36 The lower ball joint is load carrying in this type of suspension because the weight of the vehicle is applied through the spring, lower control arm, and ball joint to the wheel.

back into the control arm by *tension.* The type used is determined by the chassis design engineer, and the service technician cannot change the type of ball joint used for a particular application. ● **SEE FIGURE 111–37**.

A specific amount of stud-turning resistance is built into each ball joint to stabilize steering. A ball joint that does not support the weight of the vehicle and acts as a suspension pivot is often called a follower ball joint or a friction ball joint. The load-carrying (weight-carrying) ball joint is subjected to the greatest amount of wear and is the most frequently replaced.

STRUT RODS Some vehicles are equipped with round steel rods that are attached between the lower control arm at one end and the frame of the vehicle with rubber bushings, called strut rod bushings, at the other end. The purpose of these **strut rods** is to provide forward/backward support to the control arms. Strut rods are used on vehicles equipped with MacPherson struts and many short-/long-arm-type suspensions. The bushings are very important in maintaining proper wheel alignment while providing the necessary up-and-down movement of the control arms during suspension travel. Strut rods prevent lower control arm movement back and forth during braking. ● **SEE FIGURE 111–38**.

Strut rods are also called tension or compression rods or simply TC rods. Tension rods attach in *front* of the wheels to the body or frame where the rod is being pulled in tension. Compression rods attach to the body or frame *behind* the wheels where the rod is being pushed or compressed. Some vehicle manufacturers call the strut rod a drag rod because it is attached in front of the wheels, and therefore acts on the lower control arm as if to drag the wheels behind their attachment points.

The bushings are replaceable by removing a nut on the frame end of the strut rod. ● **SEE FIGURE 111–39**. If a strut rod has a nut on *both* sides of the bushings, then the strut rod is used to adjust *caster.*

STABILIZER BARS Most cars and trucks are equipped with a **stabilizer bar** on the front suspension, which is a round, hardened steel bar (usually SAE 4560 or 4340 steel) attached to both lower control arms with bolts and rubber bushing washers called stabilizer bar bushings. ● **SEE FIGURE 111–40**.

A stabilizer bar is also called an anti-sway bar (sway bar) or anti-roll bar (roll bar). A stabilizer bar operates by *twisting* the bar if one side of the vehicle moves up or down in relation to the other side, such as during cornering, hitting bumps, or driving over uneven road surfaces. ● **SEE FIGURE 111–41**.

The purpose of the stabilizer bar is to prevent excessive body roll while cornering and to add stability while driving over rough road surfaces. The stabilizer bar is also used as a longitudinal (front/back) support to the lower control arm on many vehicles equipped with MacPherson struts. The effective force of a stabilizer bar is increased with the diameter of the bar. Therefore, optional suspensions often include larger-diameter stabilizer bars and bushings.

Stabilizer links connect the ends of the stabilizer bar to the lower control arm. ● **SEE FIGURES 111–42 AND 111–43**. Careful inspection of the stabilizer bar links is important. Links are commonly found to be defective (cracked rubber washers or broken spacer bolts) because of the great amount of force that is transmitted through the links and the bushings. Defective links and/or bushings can cause unsafe vehicle handling and noise.

SHOCK ABSORBERS

PURPOSE AND FUNCTION **Shock absorbers** are used on all conventional suspension systems to dampen and control the motion of the vehicle's springs. Without shock absorbers (dampers), the vehicle would continue to bounce after hitting bumps. ● **SEE FIGURE 111–44**.

The major purpose of any shock or strut is to control ride and handling. Standard shock absorbers *do not* support the weight of a vehicle. *The springs support the weight of the vehicle; the shock absorbers control the actions and reactions of the springs*. Shock absorbers are also called dampers.

Most shock absorbers are *direct acting* because they are connected directly between the vehicle frame or body and the axles. ● **SEE FIGURE 111–45**.

SHOCK ABSORBER PRINCIPLE
(d)

FIGURE 111–44 (a) Movement of the vehicle is supported by springs without a dampening device. (b) Spring action is dampened with a shock absorber. (c) The function of any shock absorber is to dampen the movement or action of a spring, similar to using a liquid to control the movement of a weight on a spring (d).

As a wheel rolls over a bump, the wheel moves toward the body and compresses the spring(s) of the vehicle. As the spring compresses, it stores energy. The spring then releases this stored energy, causing the body of the vehicle to rise (rebound). ● **SEE FIGURE 111–46**.

After the energy in the spring is used up, the body starts downward, causing the spring to compress. Without shock absorbers, the energy released from the spring would be very rapid and violent. The shock absorber helps dampen the rapid up-and-down movement of the vehicle springs by converting energy of movement into heat by forcing hydraulic fluid through small holes inside the shock absorber.

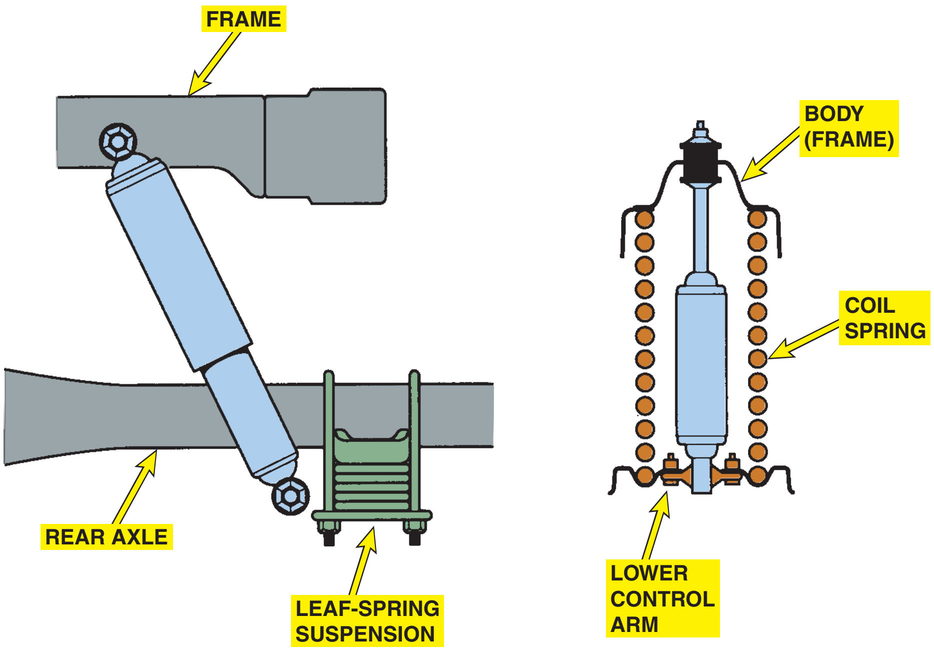

FIGURE 111–45 Shock absorbers work best when mounted as close to the spring as possible. Shock absorbers that are mounted straight up and down offer the most dampening.

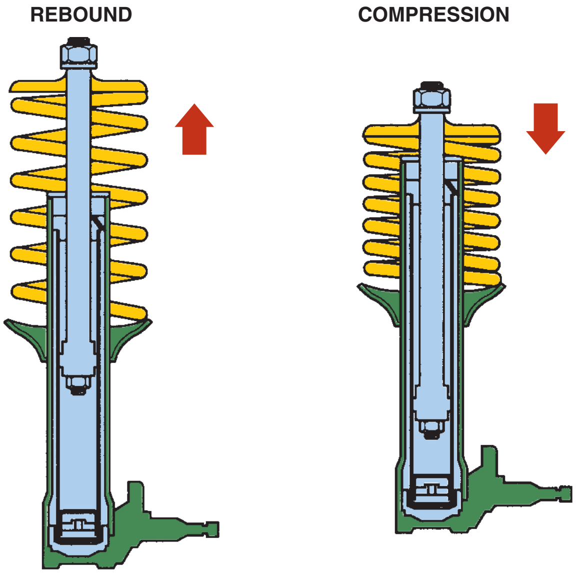

FIGURE 111–46 When a vehicle hits a bump in the road, the suspension moves upward. This is called compression or jounce. Rebound is when the spring (coil, torsion bar, or leaf) returns to its original position.

SHOCK ABSORBER OPERATION The hydraulic shock absorber operates on the principle of fluid being forced through a small opening (orifice). ● **SEE FIGURES 111–47 AND 111–48.** Besides small openings, pressure relief valves are built into most shock absorbers to control vehicle ride under all operating conditions. The greater the pressure drop of the fluid inside the shock and the greater the amount of fluid moved through the orifice, the greater the amount of dampening. Therefore, larger shock absorbers can usually provide better dampening than smaller units.

GAS-CHARGED SHOCKS Most shock absorbers on new vehicles are gas charged. Pressurizing the oil inside the shock absorber helps smooth the ride over rough roads. This pressure helps prevent air pockets from forming in the shock absorber oil as it passes through the small passages in the shock. After the oil is forced through small passages, the pressure drops and the oil expands. As the oil expands, bubbles are created. The oil becomes foamy. This air-filled oil does not effectively provide dampening. The result of all of this aeration (air being mixed with the oil) is lack of dampening and a harsh ride.

The use of higher-pressure radial tires and lighter vehicle weight has created the need for more effective shock absorbers. To meet this need, shock absorber design engineers use a pressurized gas that does not react chemically with the oil in the shock. If a substance does not react with any other substances, it is called *inert.* The gas most often used is nitrogen, which is about 78% of our atmosphere. Typical gas-charged shocks are pressurized with 130 to 150 PSI (900 to 1,030 kPa) to aid in both handling and ride control. Some shocks use higher pressures, but the higher the pressure, the greater the possibility of leaks and the harsher the ride.

Some gas-charged shock absorbers use a single tube that contains two pistons that separate the high-pressure gas from the working fluid. Single-tube shocks are also called monotube or DeCarbon after the French inventor of the principle and manufacturer of suspension components. ● **SEE FIGURE 111–49.**

AIR SHOCKS/STRUTS Air-inflatable shock absorbers or struts are used in the rear of vehicles to provide proper vehicle ride height while carrying heavy loads. Many air shock/strut units are original equipment. They are often combined with a built-in air compressor and ride height sensor(s) to provide automatic ride height control.

Air-inflatable shocks are standard shock absorbers with an air chamber with a rubber bag built into the dust cover (top) of the shock. ● **SEE FIGURE 111–50.**

Air pressure is used to inflate the bag, which raises the installed height of the shock. As the shock increases in height, the rear of the vehicle is raised. Typical maximum air pressure in air shocks ranges from 90 to 150 PSI (620 to 1,030 kPa). As the air pressure increases in the air-inflatable reservoir of the shock, the stiffness of the suspension increases. This additional stiffness is due to the shock taking weight from the spring, and therefore the air in the air shock becomes an air spring. Now, with two springs

to support the vehicle, the spring rate increases and a harsher ride often results. *It is important that the load capacity of the vehicle not be exceeded or serious damage can occur to the vehicle's springs, axles, bearings, and shock support mounts*.

AIR SPRINGS Some electronically controlled suspension systems use air springs. A basic **air spring** consists of a rubber air chamber, generally closed at the bottom by a piston fitted into a control arm, or by a strut shock absorber. ● **SEE FIGURE 111–51**.

Electronically controlled suspension systems that use air springs as the only springs are available on some Hummer and many Ford, Mercury, and Lincoln vehicles.

Some air springs are in effect auxiliary springs inside a coil-spring strut. In these designs, the coil spring supports the

weight of the vehicle, while the air spring raises or lowers the body to adjust ride height according to load. ● **SEE FIGURE 111–52**.

COIL-OVER SHOCKS A coil-over shock absorber uses the force of an external coil spring to boost the performance of the basic shock absorber. ● **SEE FIGURE 111–53**. The spring usually extends from the upper shock mount to a seat on the lower portion of the cylinder. The spring rate added to the hydraulic resistance makes the shock stiffer.

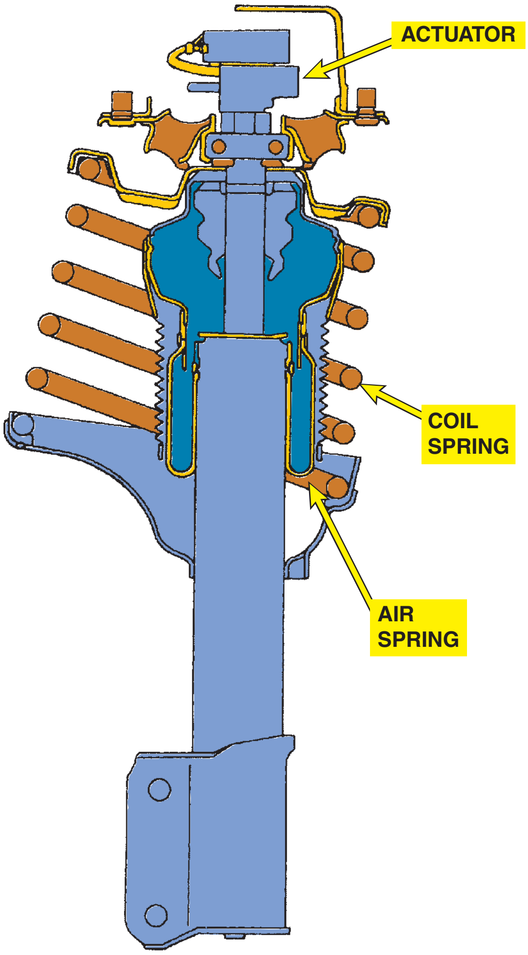

FIGURE 111–52 Some air springs are auxiliary units to the coil spring and are used to control ride height while the coil spring is the weight-bearing unit.

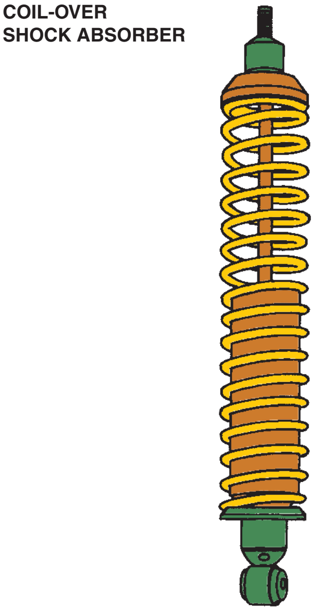

FIGURE 111–53 A coil-over shock is a standard hydraulic shock absorber with a coil spring wrapped around it to increase stiffness and/or take some of the carrying weight off of the springs.

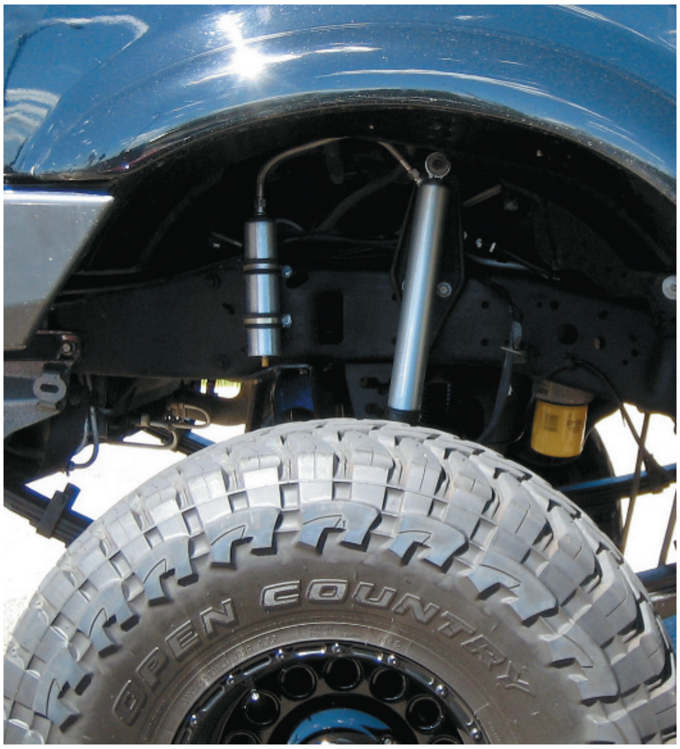

FIGURE 111–54 The shock absorber is on the right and the fluid reservoir for the shock is on the left.

FREQUENTLY ASKED QUESTION

What Are Remote Reservoir Shocks?

Remote reservoir shock absorbers are units designed for heavy-duty use that use a separate container for the working fluid. ● **SEE FIGURE 111–54**.

The purpose of the remote fluid reservoir is to keep the temperature of the fluid stable, which helps the shock absorber provide consistent dampening under all conditions.

STRUTS

PURPOSE AND FUNCTION A **strut** is a sturdy shock absorber that is also a structural component of the suspension. A strut is a suspension link as well as a shock absorber. The casing of a strut must be strong and rigid to function as a suspension link. The shock absorber assembles inside the casing of a strut and may be either a removable cartridge or an integral part of the strut.

MACPHERSON STRUTS The MacPherson strut, which is named after Earle S. MacPherson, who developed the suspension design in the late 1940s and patented it in 1953, is the most commonly used type. A MacPherson strut includes the suspension spring—a coil spring that surrounds the strut casing—so that it transfers the weight of the body to the wheel. ● **SEE FIGURE 111–55**.

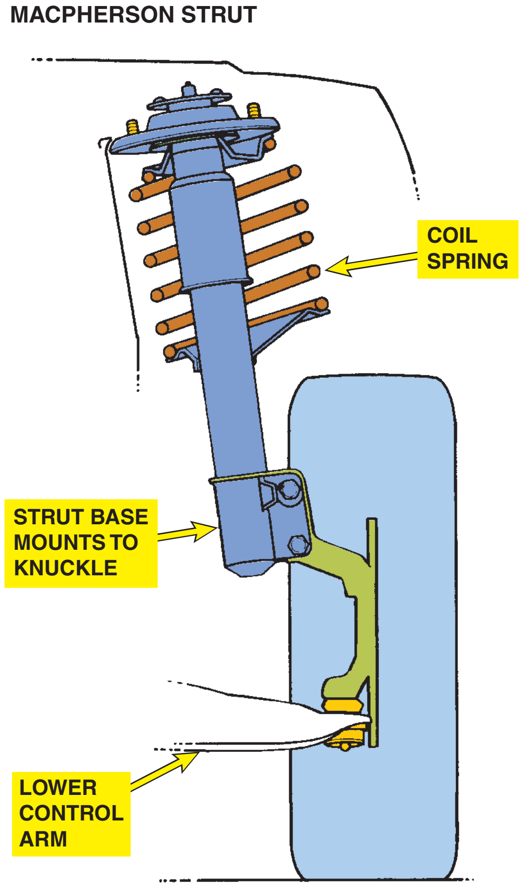

FIGURE 111–55 A strut is a structural part of the suspension and includes the spring and shock absorber in one assembly.

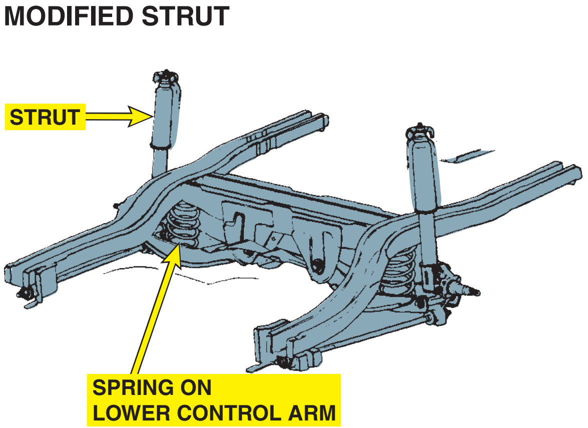

FIGURE 111–56 A modified strut used on the rear suspension; it is the structural part of the assembly.

A MacPherson strut typically incorporates an upper and a lower spring seat, a shock absorber mount and dust cap, a dust cover for the piston rod, and a bump stop. The upper mount secures the upper spring seat to the strut tower. A rubber bushing at the top of the strut absorbs vibrations. A bearing on a front-wheel strut allows it to rotate on the vertical steering axis without rubbing against the strut tower when the steering knuckle turns. The lower spring seat is attached to the strut casing.

MODIFIED STRUTS Unlike a MacPherson unit, a modified strut does not include a spring as part of the assembly and is used in the front on some vehicles and on the rear of others. ● **SEE FIGURE 111–56**. Most modified strut rear suspensions use coil springs mounted on the lower control arm.

BUMP STOPS

PURPOSE AND FUNCTION All suspension systems have a limit of travel. If the vehicle hits a large bump in the road, the wheels are forced upward toward the vehicle with tremendous force. This force is absorbed by the springs of the suspension system. If the bump is large enough, the suspension is compressed to its mechanical limit. Instead of allowing the metal components of the suspension to hit the frame or body of the vehicle, a rubber or foam bumper is used to absorb and isolate the suspension from the frame or body. ● **SEE FIGURES 111–57 AND 111–58**.

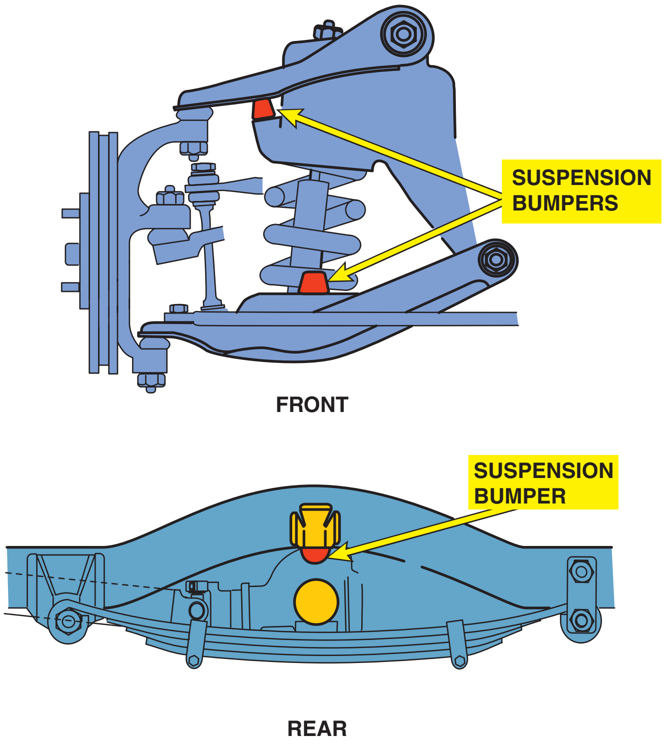

FIGURE 111–57 Suspension bumpers are used on all suspension systems to prevent metal-to-metal contact between the suspension and the frame or body of the vehicle when the suspension "bottoms out" over large bumps or dips in the road.

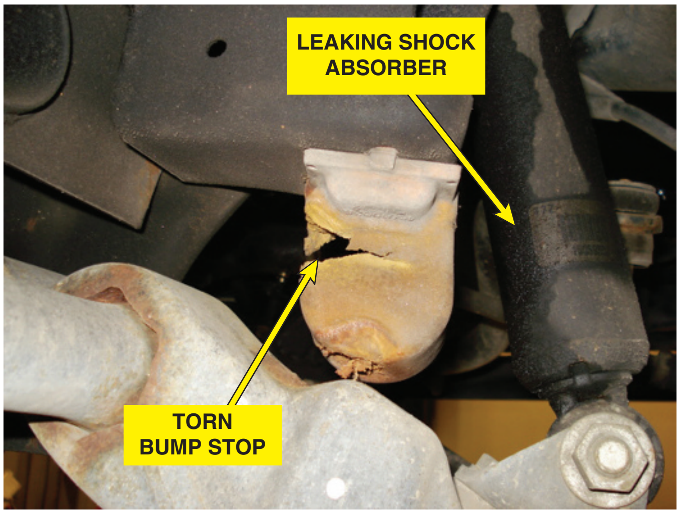

FIGURE 111–58 A bad suspension bumper (strike-out bumper) that was likely caused by a defective shock absorber. Both will require replacement.

These bumpers are called **bump stops**, suspension bumpers, strike-out bumpers, or jounce bumpers. *Jounce* means jolt, or to cause to bounce or move up and down. Bumpers are made from rubber or microcellular urethane. Urethane is a high-strength material with good resistance to wear and tear as well as good chemical resistance to most fluids. Forming urethane foam with small, regular air cells makes the material ideal for jounce bumpers.

Damaged suspension-limiting bump stops can be caused by the following:

1. Sagging springs that result in lower-than-normal ride (trim) height
2. Worn or defective shock absorbers

Most suspensions also use a rubber or foam stop to limit the downward travel of the suspension during rebound. The rebound stop also prevents metal-to-metal contact of the suspension on the frame when the vehicle is on a body-contact-type hoist and the wheels are allowed to hang or droop down. Some stops are built into the shock absorber or strut.

FREQUENTLY ASKED QUESTION

What Is a Track Rod?

A track rod, also called a Panhard rod, is used in the rear of some suspension systems to keep the rear axle centered under the center of the vehicle. It is a straight rod or channel that connects to the frame on one end and the axle on the other end.

FRONT SUSPENSION TYPES

SOLID AXLES Early cars and trucks used a solid (or *straight*) front axle to support the front wheels. ● **SEE FIGURE 112–1**.

A solid-axle front suspension is very strong and is still being used in the manufacture of medium and heavy trucks. The main disadvantage of solid-axle design is its lack of ride quality. When one wheel hits a bump or dip in the road, the forces are transferred through the axle to the opposite wheel. Solid axles are currently used in the rear of many vehicles.

KINGPINS At the end of many solid I-beam or tube axles are **kingpins** that allow the front wheels to rotate for steering. Kingpins are hardened steel pins that attach the steering knuckle to the front axle, allowing the front wheels to move for steering. Kingpins usually have grease fittings to lubricate the kingpin bushings. Failure to keep these bushings lubricated with chassis grease can cause wear and freeplay or can cause the pins to become galled (seized or frozen), resulting in hard steering and/or loud noise while turning. ● **SEE FIGURE 112–2**.

TWIN I-BEAMS A **twin I-beam** front suspension was used for over 30 years on Ford pickup trucks and vans, beginning in the mid-1960s. Strong steel twin beams that cross provide independent front suspension operation with the strength of a solid front axle. Early versions of the twin I-beam systems used kingpins, while later models used ball joints to support the **steering knuckle** and spindle. Coil springs are usually used on twin I-beam suspensions, even though the original design and patent used leaf springs. ● **SEE FIGURE 112–3**.

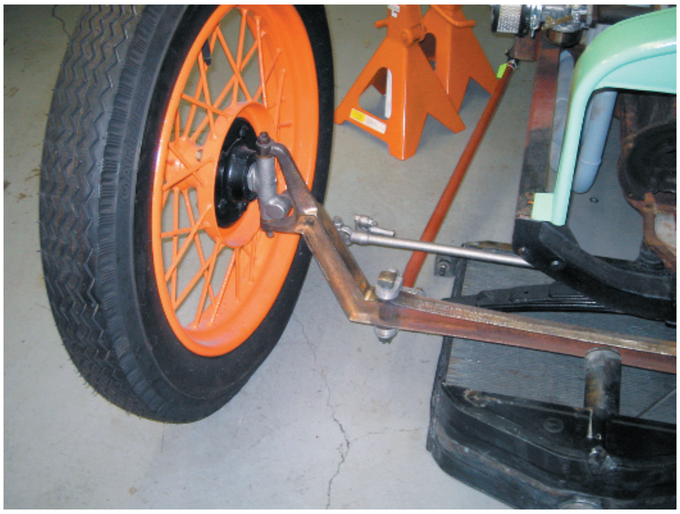

FIGURE 112–1 Most early vehicles used single straight axles.

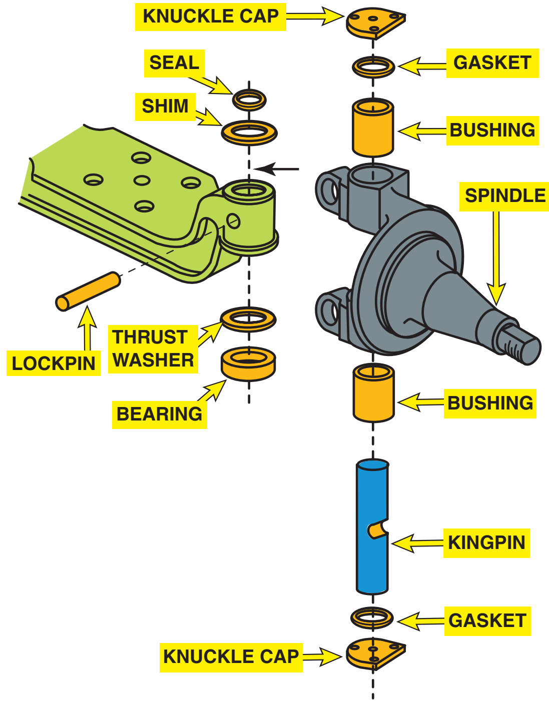

FIGURE 112–2 Typical kingpin used with a solid axle.

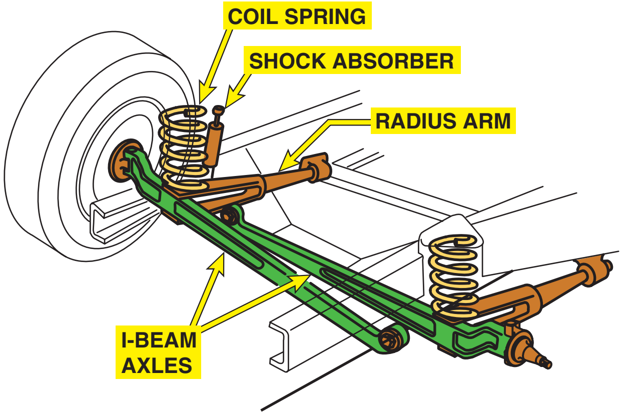

FIGURE 112–3 Twin I-beam front suspension. Rubber bushings are used to support the I-beams to the frame and help isolate road noise.

TECH TIP

Radius Rod Bushing Noise

When the radius rod bushing on a Ford truck or van deteriorates, the most common complaint from the driver is noise. ● **SEE FIGURE 112–4**. Besides causing tire wear, worn or defective radius rod bushing can cause the following:

1. A clicking sound when braking (it sounds as if the brake caliper may be loose).
2. A clunking noise when hitting bumps.

When the bushing deteriorates, the axles move forward and backward with less control. Noise is the first sign that something is wrong. Without proper axle support, handling and cornering can also be affected.

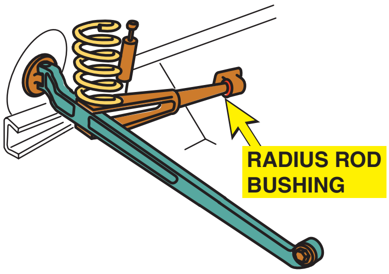

FIGURE 112–4 The rubber radius rod bushing absorbs road shocks and helps isolate road noise.

To control longitudinal (front-to-back) support, a **radius rod** is attached to each beam and is anchored to the frame of the truck using rubber bushings. These bushings allow the front axle to move up and down while still insulating road noise and vibration from the frame and body.

SHORT-/LONG-ARM SUSPENSIONS

TERMINOLOGY The short-/long-arm suspension uses a short upper control arm and a longer lower control arm and is usually referred to as the *SLA-type suspension.*

The two main links in a **short-/long-arm (SLA)** suspension are the upper control arm and the lower control arm. The upper control arm is shorter than the lower one. ● **SEE FIGURE 112–5**. This type of suspension system goes by a variety of names, including unequal-arm suspension, double-wishbone suspension, or **A-arm** suspension. Unequal arm refers to the fact that the two arms are of different lengths, while double-wishbone and A-arm derive from the shape of the arms, which are frequently triangular with one mounting point at the knuckle and two at the frame. When an SLA suspension uses a straight, two-point lower control arm, there is almost always a strut rod that braces the lower arm against the frame. The strut rod can attach to the frame at a point either forward or to the rear of the control arm.

STRUT RODS A strut rod, also called a *reaction rod,* provides support to the axle during braking and acceleration forces.

Using a strut rod provides triangulation between the wheel and the frame. *Triangulation* means that the front suspension has a three-point brace that resists forces from every direction while still allowing the wheels to pivot on the steering axis.

COIL SPRING FRONT SUSPENSIONS Locating the coil spring on the lower control arm is the most common SLA-type suspension configuration. ● **SEE FIGURE 112–6**.

The upper control arm is A-shaped, with two mounting points at the frame side member and one at the steering knuckle. The inboard ends of the arm attach to a pivot bar that is rigidly bolted to the frame, and the outboard end connects to the steering knuckle with a ball joint. Bushings between the inner arm mounts and the pivot bar allow the arm to swing vertically. The lower control arm is also A-shaped with two inboard pivot mounts and a ball joint connection at the knuckle. Bolts attach the inboard ends of the lower arm to brackets that extend from the bottom of the frame crossmember. Bushings on the inboard mounts allow the arm to pivot vertically.

The coil springs seat between the lower control arm and a bracket below the frame side member. The shock absorber attaches to the lower control arm and the frame side member.

In a typical coil spring on the upper control arm design, a portion of the unit-body wheel well is reinforced to withstand spring force and act as the upper spring seats. ● **SEE FIGURE 112–7**.

TORSION BAR FRONT SUSPENSION Short-/long-arm suspensions use longitudinal torsion bars, especially in trucks.

The forward end of the torsion bar has external splines and shares the splined socket of the torque arm with the control arm through a bolt. Because the torque arm is rigidly bolted to the control arm, motion transfers to the torsion bar whenever the control arm pivots. The torsion bar extends rearward from the control arm and connects to an anchor arm that attaches to a frame crossmember. The torsion bar splines to the anchor arm and the anchor arm is secured to the frame by a bolt and adjusting nut. The adjusting nut varies the spring force of the torsion bar to establish the ride height of the vehicle. ● **SEE FIGURE 112–8**.

FREQUENTLY ASKED QUESTION

What Is a Coil-Over-Shock Suspension?

In some applications, the spring and shock absorber are combined to fit within the upper and lower A-arms. This makes for a simple and lightweight front-type suspension and is used in a variety of vehicles including light pickup trucks. ● **SEE FIGURE 112–9.**

STRUT SUSPENSION

PARTS AND OPERATION **Strut suspension** can be of several types. A MacPherson strut includes the suspension spring that transfers the weight of the body to the wheel. A MacPherson strut is the main, load-carrying suspension spring. ● **SEE FIGURE 112–10.**

A MacPherson strut typically incorporates an upper and a lower spring seat, a shock absorber mount and dust cap, a dust cover for the piston rod, and a bump stop. The upper mount secures the upper spring seat to the strut tower. A rubber bushing at the top of the strut absorbs vibrations. In most applications, a bearing on the top of a front-wheel strut allows it to rotate on the vertical steering axis without rubbing against the strut tower

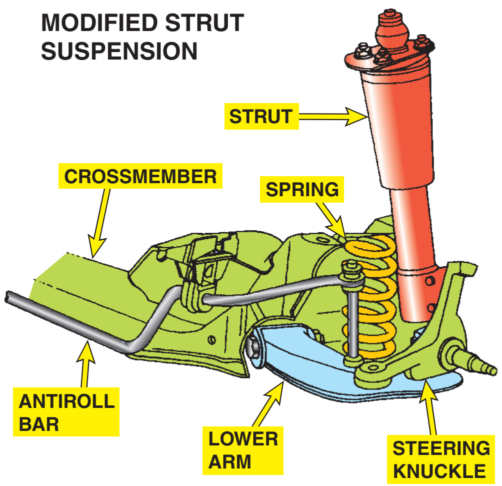

FIGURE 112–11 The modified strut front suspension is similar to a MacPherson strut suspension except that the coil spring is seated on the lower control arm and is not part of the strut assembly.

when the steering knuckle turns. The lower spring seat is attached to the strut casing. The piston rod dust cover is similar to the dust cover on a conventional shock absorber, and a bump stop at the top of the piston rod keeps the strut from bottoming out during suspension jounce.

A modified strut does not include a spring as part of the assembly. ● **SEE FIGURE 112–11**. A modified strut is used on the rear of some GM vehicles. Except for the lack of a spring and spring seats, the construction and function of a modified strut are basically the same as those of a MacPherson strut. When used on the front suspension, a modified strut also rotates on the steering axis when the wheels turn.

A multilink front suspension uses two control arms as well as a structural strut assembly. This type of suspension is also called a strut/SLA or long spindle, and short-/long-arm suspension. ● **SEE FIGURE 112–12**.

SERVICING THE SUSPENSION SYSTEM

Suspension systems are designed and manufactured to provide years of trouble-free service with a minimum amount of maintenance. In fact, the suspension system is often not noticed at all by the driver because the vehicle rides and handles as expected. It is when the driver notices that the vehicle is not riding or handling as it did, or should, that a technician is asked to repair or align the vehicle and fix the problem.

The smart technician should always road test any vehicle before and after servicing (see Tech Tip for details). *The purpose of any diagnosis is to eliminate known good components.* (See the suspension problem symptom chart for a list of components that can cause the problem or customer complaint.)

CAUTION: More than one factor may be the cause of a problem. Be sure to inspect all suspension components, and repair all parts that are worn or damaged. Failure to do so may allow the problem to reoccur and cause premature failure of other suspension components.

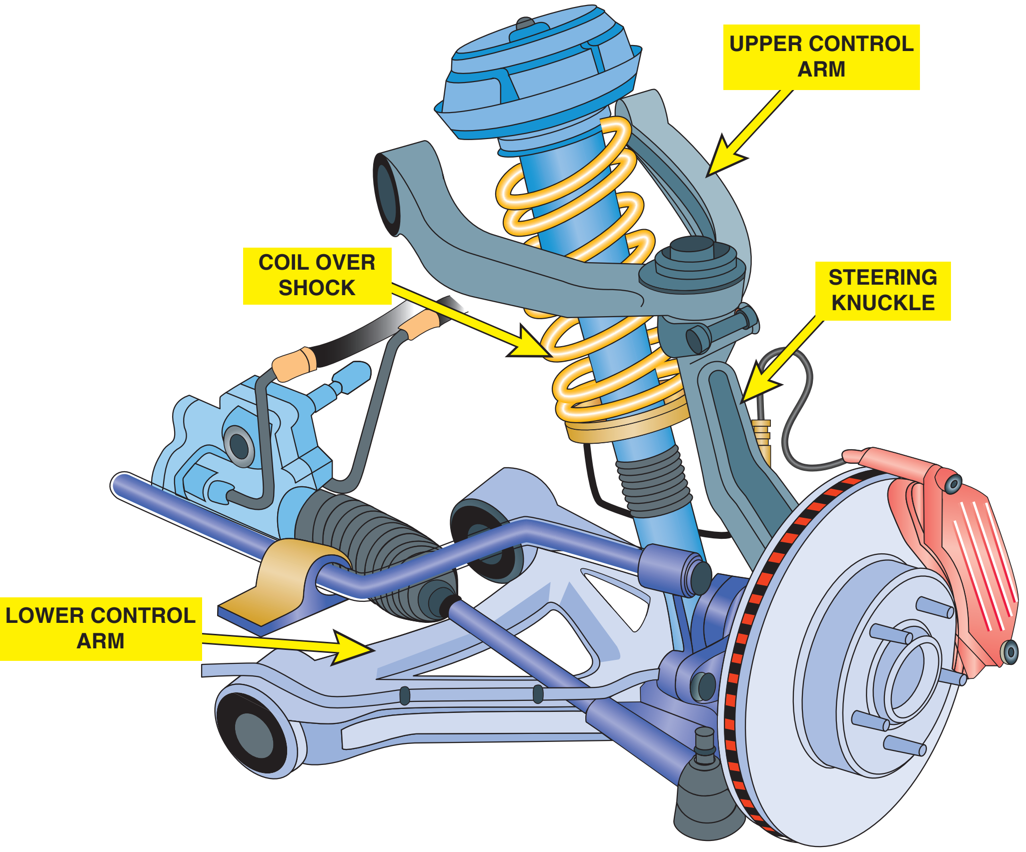

FIGURE 112–12 A typical multilink front suspension system.

ROAD TEST DIAGNOSIS If possible, perform a road test of the vehicle with the owner of the vehicle. It is also helpful to have the owner drive the vehicle. While driving, try to determine when and where the noise or problem occurs, such as the following:

1. In cold or warm weather
2. With cold or warm engine/vehicle
3. While turning, left only, right only

A proper road test for any suspension system problem should include the following:

1. **Drive beside parked vehicles.** Any noise generated by the vehicle suspension or tires is reflected off solid objects, such as a row of parked vehicles along a street. For best results, drive with the windows down and drive close to the parked vehicles or a retaining wall on the left side. Repeat the drive for the right side. Defective wheel bearings or power steering pumps usually make noise and can be heard during this test.
2. **Drive into driveways.** Suspension problems often occur when turning at the same time the suspension hits a bump. This action is best repeated by driving slowly into a driveway with a curb. The curb causes the suspension to compress while the wheels are turned (see the Case Study titled "The Rock-Hard Problem" for an example). Defective stabilizer bar bushings, control arm bushings, and ball joints will usually make noise during this test procedure. ● **SEE CHART 112–1.**
3. **Drive in reverse while turning.** This technique is usually used to find possible defective outer constant-velocity (CV) joints used on the drive axle shaft of front-wheel-drive vehicles. This technique also forces the suspension system to work in reverse of normal. Any excessive clearances in the suspension system are reversed and often make noise or cause a vibration during the test. Besides defective CV joints, this test can often detect worn control arm bushings, ball joints, stabilizer bar bushings, or links. This test can also

detect defective or worn steering system components such as an idler arm, tie rod end, or center link.

4. **Drive over a bumpy road.** Worn or defective suspension (and steering) components can cause the vehicle to bounce or dart side to side while traveling over bumps and dips in the road. Worn or defective ball joints, control arm bushings, stabilizer bar bushings, stabilizer bar links, or worn shock absorbers can be the cause.

Once the problem has been confirmed, a further inspection can be performed in the service bay.

DRY PARK TEST (SUSPENSION) A **dry park test** can also be used to help locate worn or defective suspension components. The dry park test is performed by having an assistant move the steering wheel side to side while feeling and observing for any freeplay in the steering or suspension. For best results, the vehicle should be on a level floor or on a drive-on-type hoist with the front wheels pointing straight ahead. In this suspension analysis using the dry park test, the technician should observe the following for any noticeable play or unusual noise:

1. **Front wheel bearings.** Loose or defective wheel bearings are often overlooked as a possible cause of poor handling or darting vehicle performance.
2. **Control arm bushing wear or movement.** Check for any abnormal movement in upper control arm bushings or lower control arm bushings.
3. **Ball joint movement.** Check for any noticeable play or noise from both load-carrying and follower-type ball joints on both sides of the vehicle.

NOTE: The dry park test (and many other chassis system tests) relies on the experience of the technician to be able to judge normal wear from abnormal wear. It is extremely important that all beginning technicians work closely with an experienced technician to gain this knowledge.

TECH TIP

Road Test—Before and After

Many times, technicians will start to work on a vehicle based on the description of the problem by the driver or owner. A typical conversation was overheard where the vehicle owner complained that the vehicle handled "funny," especially when turning. The owner wanted a wheel alignment, and the technician and shop owner wanted the business. The vehicle was aligned, but the problem was still present. The real problem was a defective tire. The service technician should have road tested the vehicle *before* any service work was done to confirm the problem and try to determine its cause. Every technician should test-drive the vehicle *after* any service work is performed to confirm that the service work was performed correctly and that the customer complaint has been resolved. This is especially true for any service work involving the steering, suspension, or braking systems.

VISUAL INSPECTION All suspension components should be carefully inspected for signs of wear or damage. A thorough visual inspection should include checking all of the following:

1. Shock absorbers and struts. ● **SEE FIGURE 112–13**.
2. Springs. ● **SEE FIGURE 112–14**.
3. Stabilizer bar links
4. Stabilizer bar bushings
5. Upper and lower shock absorber mounting points
6. Bump stops
7. Body-to-chassis mounts
8. Engine and transmission (transaxle) mounts
9. Suspension arm bushings. ● **SEE FIGURE 112–15**.

Alignment equipment and procedures can often determine if a suspension component is bent or has been moved out of position. A careful *visual* inspection can often reveal suspected damaged components by observing scrape marks or rusty sections that could indicate contact with the road or another object.

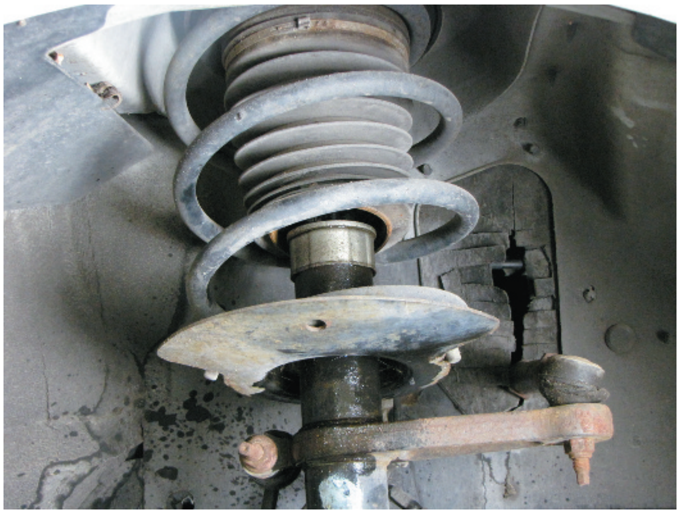

FIGURE 112–13 A leaking strut. Either a cartridge insert or the entire strut will require replacement. If a light film of oil is seen, this is to be considered normal. If oil is dripping, then this means that the rod seal has failed.

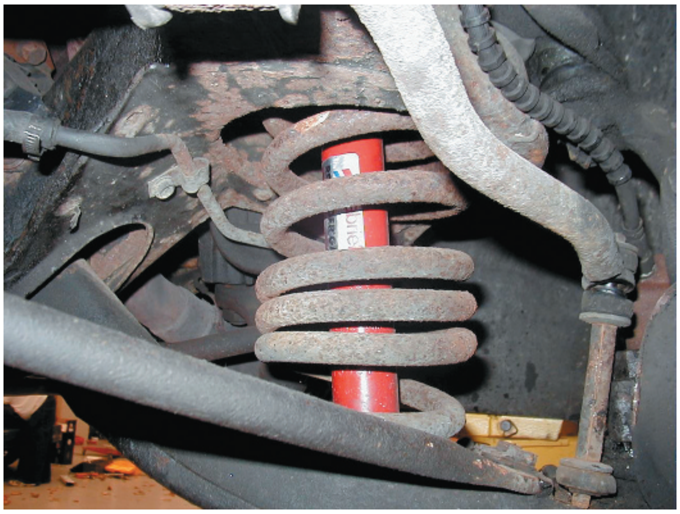

FIGURE 112–14 This front coil spring looks as if it has been heated with a torch in an attempt to lower the ride height of the vehicle. Both front springs will require replacement.

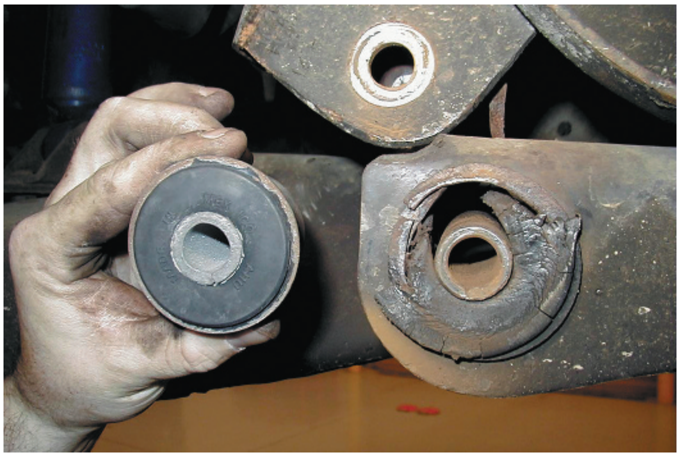

FIGURE 112–15 It is easy to see that this worn control arm bushing needs to be replaced. The new bushing is shown next to the original.

While an assistant bounces the vehicle up and down, check to see if there is any freeplay in any of the suspension components.

BALL JOINTS

DIAGNOSIS AND INSPECTION The life of ball joints depends on driving conditions, vehicle weight, and lubrication. Even with proper care and lubrication, the load-carrying (weight-carrying) ball joints wear more than the follower ball joints. Ball joints should be replaced in pairs, both lower or both upper, to ensure the best handling.

Defective or worn ball joints can cause looseness in the suspension and the following common driver complaints:

1. Loud popping or squeaking whenever driving over curbs, such as into a driveway
2. Shimmy-type vibration felt in the steering wheel
3. Vehicle wander or a tendency not to track straight
4. Excessive freeplay in the steering wheel

A ball joint inspection should also be done when an alignment is performed or as part of any other comprehensive vehicle inspection.

Many load-carrying ball joints have wear indicators with a raised area around the grease fitting, called **indicator ball joints**. ● **SEE FIGURES 112–16 AND 112–17**.

Always check wear-indicator-type ball joints with the wheels of the vehicle on the ground. If the raised area around the grease fitting is flush or recessed with the surrounding area, the ball joint is worn more than 0.050 inch and must be replaced.

NOTE: Most ball joints must be replaced if the joint has more than 0.050 inch axial (up-and-down) movement. To help visualize this distance, consider that the thickness of an American nickel coin is about 0.060 inch. It is helpful to know that maximum wear should be less than the thickness of a nickel. There are dial indicators (gauges) available that screw into the grease-fitting hole of the ball joint that can accurately measure the wear. ● SEE FIGURE 112–18.

To perform a proper non-indicator-type ball joint inspection, the force of the vehicle's springs *must* be *unloaded* from the ball joint. If this force is not relieved, the force of the spring pushes the ball-and-socket joint tightly together and any wear due to movement will not be detected.

FIGURE 112–17 Indicator ball joints should be checked with the weight of the vehicle on the ground.

NOTE: The location of the load-carrying ball joint is closest to the seat of the spring or torsion bar.

If the coil spring or torsion bar is attached to the *lower* control arm, the *lower* ball joint is the load-carrying ball joint. ● **SEE FIGURE 112–19**. This includes vehicles equipped with modified MacPherson-strut-type suspension. ● **SEE FIGURE 112–20**.

1. Place the jack under the lower control arm as close to the ball joint as possible and raise the wheels approximately 1 to 2 inches (2.5 to 5 cm) off the ground to unload the lower ball joint.
2. Using a prybar under the tire, lift the wheel up. If there is excessive vertical movement in the ball joint itself, it must be replaced. Most manufacturers specify a maximum vertical play of approximately 0.050 inch (1.3 mm), or the thickness of a nickel. Always check the manufacturer's specifications for exact maximum allowable movement. Vertical movement of

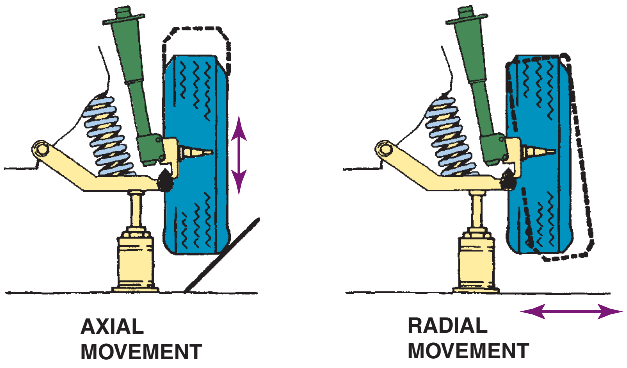
WEIGHT-CARRYING BALL JOINT

FIGURE 112–19 If the spring is attached to the lower control arm as in this SLA suspension, the jack should be placed under the lower control arm as shown. A dial indicator should be used to measure the amount of freeplay in the ball joints. Be sure that the looseness being measured is not due to normal wheel bearing endplay.



AXIAL MOVEMENT
RADIAL MOVEMENT

FIGURE 112–20 The jack should be placed under the lower control arm of this modified MacPherson-type suspension.

a ball joint is often called axial play because the looseness is in the same axis as the ball joint stud. To check for *lateral* play, grip the tire at the top and bottom and move your hands in opposite directions.

NOTE: Be sure that the cause of any freeplay or looseness is not due to the wheel bearing. Closely observe the exact source of the freeplay movement.

If the coil spring is attached to the *upper* control arm, the *upper* ball joint is the load-carrying ball joint. ● **SEE FIGURE 112–21.**

1. Place a block of wood (2 × 4 in.) between the upper control arm and the frame, or use a special tool designed for this purpose. ● **SEE FIGURE 112–22.**

PRYBAR
AXIAL MOVEMENT
RADIAL MOVEMENT

FIGURE 112–21 If the spring is attached to the upper control arm, the jack should be placed under the frame to check for ball joint wear.

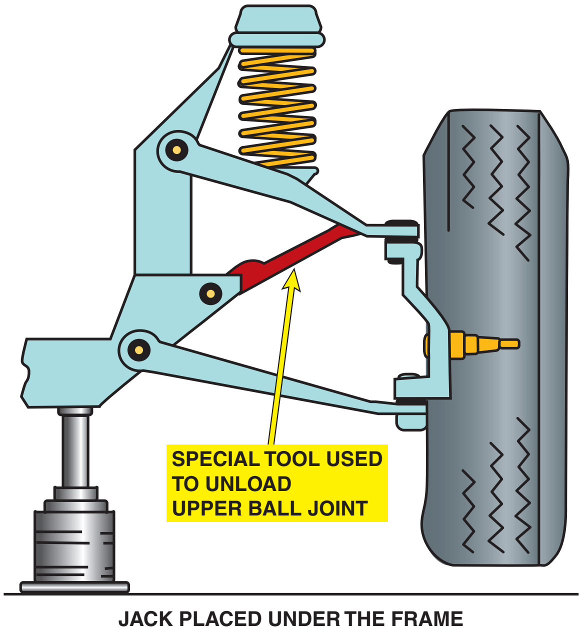

FIGURE 112–22 A special tool or a block of wood should be inserted between the frame and the upper control arm before lifting the vehicle off the ground. This tool stops the force of the spring against the upper ball joint so that a true test can be performed on the condition of the ball joint.

2. Place the jack under the vehicle's *frame* and raise the wheel approximately 1 to 2 inches off the ground. (The wood block or special tool keeps the weight of the vehicle off the upper ball joint.)
3. Using a prybar under the tire, lift the wheel. If there is excessive vertical movement in the ball joint itself, it must be replaced. Always check the manufacturer's specifications for exact maximum allowable movement.

Follower ball joints (friction ball joints) should also be inspected while testing load-carrying ball joints. Grasp the tire at the top and the bottom and attempt to shake the wheel assembly while looking directly at the follower ball joint. Generally, there should be no lateral or axial movement at all in the follower ball joint. However, some manufacturers specify a maximum of 0.250 inch (1/4 in. or 0.6 cm) measured at the top of the tire. Always check the manufacturer's specifications before condemning a ball joint because of excessive play.

MacPherson-strut-equipped vehicles do not have a load-carrying ball joint. The weight of the vehicle is carried through the upper strut mount and bearing assembly. ● **SEE FIGURE 112–23**.

After checking axial play in a ball joint, grasp the tire from the side at the top and bottom and alternately push and pull. *Any* lateral movement at the ball joint should generally be considered a good reason to replace the ball joints. ● **SEE FIGURE 112–24**.

BALL JOINT REMOVAL Take care to avoid damaging grease seals when separating ball joints from their mounts. *The preferred method to separate tapered parts is to use a puller-type tool that applies pressure to the tapered joint as the bolt is tightened on the puller.* ● **SEE FIGURE 112–25**.

Sometimes the shock of a hammer can be used to separate the ball joint from the steering knuckle. For best results, another hammer should be used as a backup while striking the joint to be separated on the side with a heavy hammer.

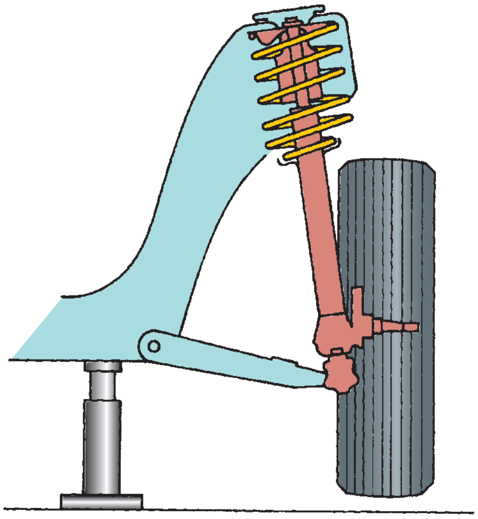

FIGURE 112–23 The jacking point is under the frame for checking the play of a lower ball joint used with a MacPherson strut.

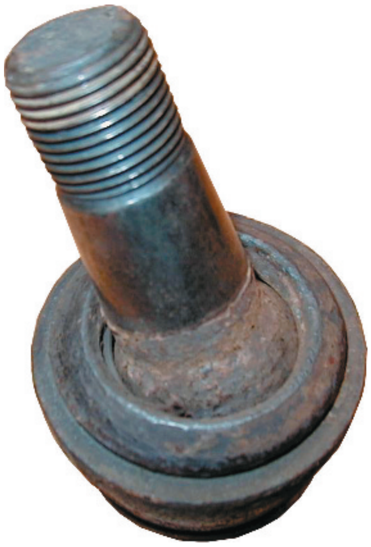

FIGURE 112–24 This worn and rusty ball joint was found by moving the wheel and looking for movement in the joint.

FREQUENTLY ASKED QUESTION

What Is the Difference between a Low-Friction Ball Joint and a Steel-on-Steel Ball Joint?

Before the late 1980s, most ball joints were constructed with a steel ball that rubbed on a steel socket. This design created friction and provided for a tight high-friction joint until wear caused looseness in the joint.

Newer designs use a polished steel ball that is installed in a hard plastic polymer, resulting in a low-friction joint assembly. Because of the difference in friction characteristics, the vehicle may handle differently than originally designed if incorrect-style ball joints are installed. Most component manufacturers state that low-friction ball joints in a vehicle originally equipped with steel-on-steel high-friction ball joints are usually acceptable, but high-friction replacement ball joints should be avoided on a vehicle originally equipped with low-friction ball joints.

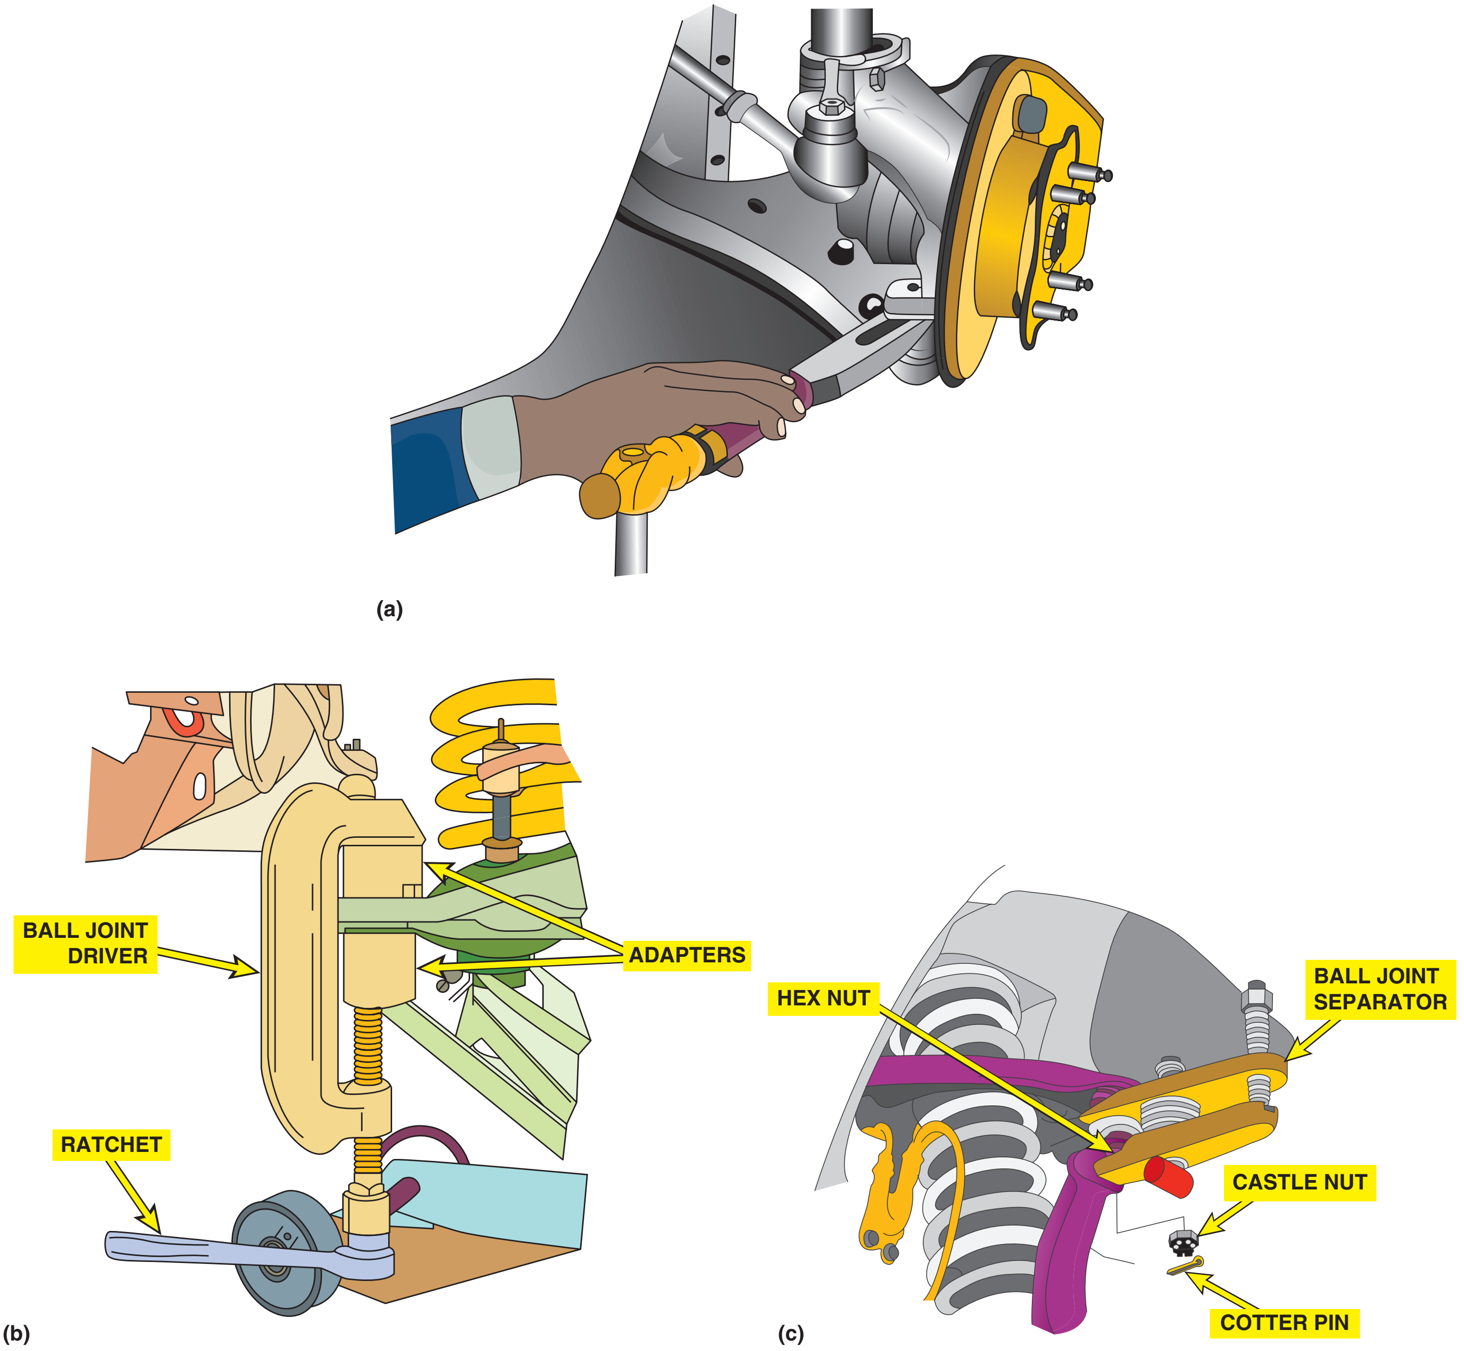

FIGURE 112–25 (a)Taper breaker tool being used to separate the upper ball joint from the steering knuckle. However, this tool will destroy the dust boot and should only be used if the ball joint is going to be replaced. (b) A ball-joint press is the most recommended tool to use when removing or installing ball joints. (c) A spreader-type tool being used to separate the tapered stud from the steering knuckle. Often striking the knuckle with a heavy hammer is enough to "break the taper" of the stud and release it from the knuckle.

CAUTION: The use of tapered "pickle forks" should be avoided, unless the part is to be replaced, because they often damage the grease seal of the part being separated.

Some ball-joint studs have a slot or groove where a **pinch bolt** is used to hold the ball joint to the steering knuckle. ● **SEE FIGURE 112–26**. Use penetrating oil in the steering knuckle groove and rotate the knuckle several times. Do not use a hammer on the pinch bolt because this can cause damage to the bolt and the ball joint. Do not widen the slot in the steering knuckle. Once separated, check the shape of the steering knuckle. ● **SEE FIGURE 112–27**. If the pinch bolt has been deformed by overtightening, the steering knuckle should be replaced.

When removing ball joints that are riveted in place, always cut off or drill rivet heads before separating the ball joint from the spindle. This provides a more solid base to assist in removing rivets. *The preferred method to remove rivets from ball joints is to center punch and drill out the center of the rivet before using a drill or an air-powered chisel to remove the rivet heads.* Be careful not to drill or chisel into the control arms. ● **SEE FIGURES 112–28 THROUGH 112–30**.

Press-in-type ball joints are removed and installed using a special C-clamp-type tool. ● **SEE FIGURE 112–31**.

NOTE: Many replacement press-in-type ball joints are slightly larger in diameter—about 0.050 inch (1.3 mm)—than the original ball joint to provide the same press fit. If the ball joints have been replaced before, then the control arm must be replaced.

Avoid using heat to remove suspension or steering components. Many chassis parts use rubber and plastic that can be

CASE STUDY

The Rattle Story

A customer complained that a rattle was heard every time the vehicle hit a bump. The noise sounded as if it came from the rear. All parts of the exhaust system and suspension system were checked. Everything seemed okay until the vehicle was raised with a frame-type hoist instead of a drive-on type. Then, whenever the right rear wheel was lifted, the noise occurred. The problem was a worn (elongated) shock absorber mounting hole. A washer with the proper-size hole was welded over the worn lower frame mount and the shock absorber was bolted back into place.

Summary:

Complaint—Vehicle owner complained of a rattle sound from the rear suspension at times.
Cause—The lower shock mount was found to be worn (elongated) causing the noise.
Correction—A steel washer was welded over the worn lower frame mount which restored the shock mount to the correct size and solved the noise issue.

damaged if heated with a torch. *If heat is used to remove a part, it must be replaced.* For best results, try soaking with a penetrating oil and use the proper tools and procedures as specified by the manufacturer.

Many vehicles are equipped with nonreplaceable ball joints, and the entire control arm must be replaced if the ball joint is worn or defective.

CAUTION: Always follow manufacturer's recommended installation instructions whenever replacing any suspension or other chassis component part. Tie rod ends and ball joints use a taper to provide the attachment to other components. Whenever a nut is used to tighten a tapered part, it is important not to back off (loosen) the nut after tightening. As the nut is being tightened, the taper is being pulled into the taper of the adjoining part. The specified torque on the nut ensures that the two pieces of the taper are properly joined. If the cotter key does not line up with the hole in the tapered stud when the nut has been properly torqued, tighten it more to line up a hole—never loosen the nut.

SHOCK ABSORBERS AND STRUTS

DIAGNOSIS Shock absorber life depends on how and where the vehicle is driven. Original equipment (OE) shock absorbers are carefully matched to the vehicle springs and bushings to provide the best ride comfort and control. As the control arm bushings and ball joints age, the energy built up in the springs of the vehicle is controlled less by the friction of these joints and bushings, requiring more control from the shock absorbers. Shock absorber action is also reduced as the seals inside wear.

Replacement of shock absorbers may be required when any or all of the following symptoms appear:

1. **Ride harshness.** As the effectiveness of the shock absorber decreases, the rapid forces of the springs are not as dampened or controlled. Worn shocks can cause ride harshness and yet not cause the vehicle to bounce after hitting a bump.
2. **Frequent bottoming out on rough roads.** Shock absorbers provide a controlled movement of the axle whenever the vehicle hits a bump or dip in the road. As fluid is lost or wear occurs, the shock absorber becomes weaker and cannot resist the forces acting on the axle. The worn shock absorber can allow the spring to compress enough so that the axle contacts the jounce bumper (bump stop) on the body or frame of the vehicle.

NOTE: Frequent bottoming out is also a symptom of reduced ride height due to sagging springs. Before replacing the shock absorbers, always check for proper ride height as specified in the vehicle service manual or any alignment specification booklet available from suppliers or companies of alignment or chassis parts and equipment.

3. **Extended vehicle movement after driving on dips or a rise in the road.** The most common shock absorber test is the bounce test. Push down on the body of the vehicle and let go; the vehicle should return to its normal ride height and stop. Worn shock absorbers can cause poor driver control due to excessive up-and-down suspension movements. If the vehicle continues to bounce two or three times, then the shocks or struts are worn and must be replaced.
4. **Cuppy-type tire wear.** Defective shock absorbers can cause **cuppy tire wear**. This type of tire wear is caused by the tire's bouncing up and down as it rotates.
5. **Leaking hydraulic oil.** When a shock or strut leaks oil externally, this indicates a defective seal. The shock absorber or strut cannot function correctly when low on oil inside.

TECH TIP

The Shock Stud Trick

Front shock absorbers used on many rear-wheel-drive vehicles equipped with an SLA-type front suspension are often difficult to remove because the attaching nut is rusted to the upper shock stub. A common trick is to use a deep-well 9/16 inch socket and a long extension and simply bend the shock stud until it breaks off. At first you would think that this method causes harm, and it does ruin the shock absorber—but the shock absorber is not going to be reused and will be discarded anyway.

The usual procedure followed by many technicians is to simply take a minute or two to break off the upper shock stud, then hoist the vehicle to allow access to the lower two shock bolts, and then the shock can easily be removed. To install the replacement shock absorber, attach the lower bolts, lower the vehicle, and attach the upper rubber bushings and retaining nut.

6. **Springs and shock absorbers should be replaced in pairs.** Both front or both rear shocks should be replaced together to provide the best handling and control.

NOTE: Shock absorbers do not affect ride height except where special air shocks or coil overload carrying shocks are used. If a vehicle is sagging on one side or in the front or the rear, the springs should be checked and replaced if necessary.

Shock absorbers are filled with fluid and sealed during production. They are not refillable; if worn, damaged, or leaking, they must be replaced. A slight amount of fluid may bleed by the rod seal in cold weather and deposit a light film on the upper area of the shock absorber. This condition will not hurt the operation of the shock and should be considered normal. If noisy when driving, always check the tightness and condition of all shock absorber mounts.

Replacement shock absorbers and/or struts should match the original equipment unit in physical size.

FRONT SHOCK REPLACEMENT Front shock absorbers provide ride control and are usually attached to the lower control arm by bolts and nuts. The upper portion of the shock usually extends through the spring housing and is attached to the frame of the vehicle with rubber grommets to help insulate noise, vibration, and harshness.

Most front shock absorbers can be replaced either with the vehicle still on the ground or while on a hoist. The front suspension of most vehicles allows the removal of the shocks without the need to support the downward travel of the lower control arm. The downward travel limit is stopped by a rubber stop or by the physical limit of the suspension arms.

Special sockets and other tools are available to remove the nut from the shocks that use a single mounting stem. The removal of the lower mounting of most front shock absorbers usually involves the removal of two bolts. After removal of the attaching hardware, the shock absorber is simply pulled through the front control arm. ● **SEE FIGURE 112–32**.

Reverse the removal procedure to install replacement shock absorbers. Always consult the manufacturer's recommended procedures and fastener tightening torque.

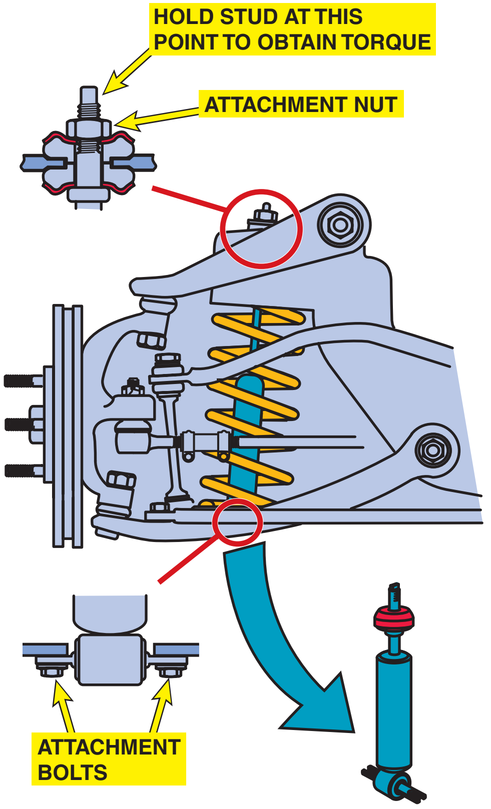

FIGURE 112–32 Most shock absorbers used on the front suspension can be removed from underneath the vehicle after removing the attaching bolts or nuts.

MACPHERSON STRUT REPLACEMENT

CAUTION: Always follow the manufacturer's recommended methods and procedures whenever replacing a MacPherson strut assembly or component.

On most vehicles equipped with MacPherson strut suspensions, strut replacement involves the following steps:

1. Hoist the vehicle, remove the wheels, and mark the attaching bolts/nuts.
2. Remove the upper strut mounting bolts except for one to hold the strut until ready to remove the strut assembly. ● **SEE FIGURE 112–33**.
3. Remove the brake caliper or brake hose from the strut housing. ● **SEE FIGURE 112–34**.

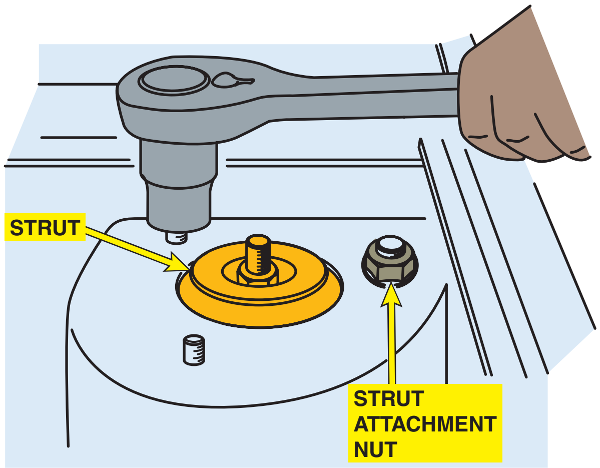

FIGURE 112–33 Removing the upper strut mounting bolts. Some experts recommend leaving one of the upper strut mount nuts loosely attached to prevent the strut from falling when the lower attaching bolts are removed.

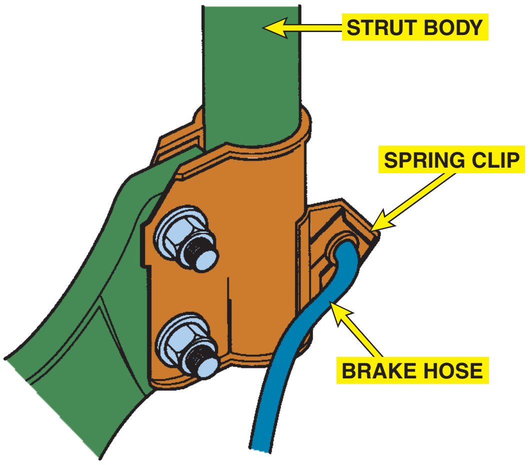
4. After removing all lower attaching bolts, remove the final upper strut bolt and remove the strut assembly from the vehicle. Place the strut assembly into a strut spring compressor fixture or use manual spring compressors as shown in ● **FIGURE 112–35**.
5. Compress the coil spring enough to relieve the tension on the strut rod nut. Remove the strut rod nut as shown in ● **FIGURE 112–36**.
6. After removing the strut rod nut, remove the upper strut bearing assembly and the spring. ● **SEE FIGURE 112–37**.



STRUT BODY
SPRING CLIP
BRAKE HOSE

FIGURE 112–34 A brake hydraulic hose is often attached to the strut housing. Sometimes all that is required to separate the line from the strut is to remove a spring clip.

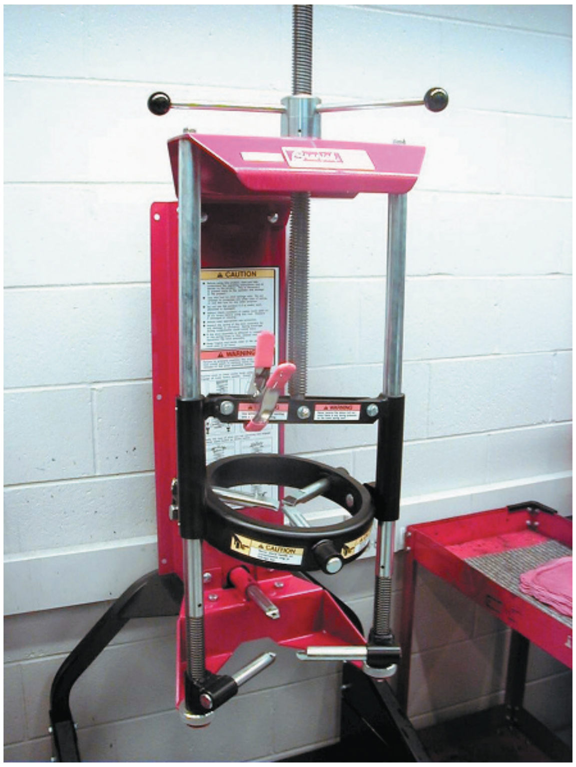


FIGURE 112–35 Use a strut spring compressor fixture to compress the spring on a MacPherson strut before removing the strut retaining nut.

NOTE: The bearing assembly should be carefully inspected and replaced if necessary. Some automotive experts recommend replacing the bearing assembly whenever the strut is replaced.

7. Most MacPherson struts are replaced as an entire unit assembly. Older struts can have the cartridge inside the housing replaced. The cartridge is installed after removing the gland nut at the top of the strut tube and removing the original strut rod, valves, and hydraulic oil. Always replace the cartridge assembly per the manufacturer's recommended procedure. ● **SEE FIGURES 112–38, 112–39, AND 112–40**.

CAUTION: Many GM front-wheel-drive vehicles use a MacPherson strut with a large-diameter spring seat area. GM chassis engineers call this a cow catcher design. If the coil spring breaks, the extra-large cow catcher will prevent the end of the broken spring from moving outward where it could puncture a tire and possibly cause an accident. Always use a replacement strut that has this feature.

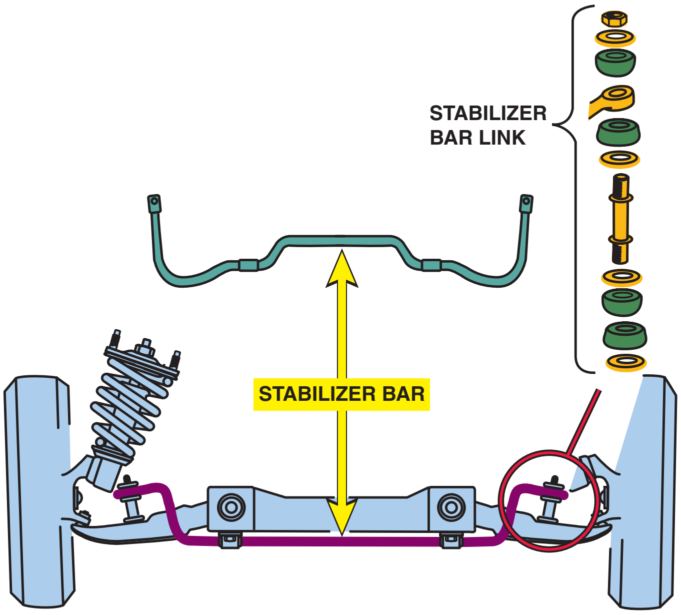
STABILIZER BAR LINKS AND BUSHINGS

DIAGNOSIS Stabilizer bars twist whenever a vehicle turns a corner or whenever one side of the vehicle rises or lowers. The more the body of the vehicle leans, the more the bar twists, and the more the bar counteracts the roll of the body. A great deal of force is transferred from the stabilizer bar to the body or frame of the vehicle through the stabilizer links at the control arm and the stabilizer bar mounting bushings on the body or frame. *The most common symptom of defective stabilizer bar links or bushings is noise while turning, especially over curbs.* When driving up and over a curb at an angle, one wheel is pushed upward. Since the stabilizer bar connects both wheels, the bar tends to resist this motion by twisting. If one or both links are broken, a loud knock or clanking sound is heard as the bar contacts the control arm. Any sound heard when driving should be investigated and the cause determined by a thorough visual inspection.

REPLACEMENT Stabilizer links are usually purchased as a kit consisting of replacement rubber bushings, retainers, a long bolt, and spacer with a nut and lock nut. General Motors recommends that stabilizer links be replaced in pairs and two kits purchased so that the links on both the left and the right can be replaced at the same time. ● **SEE FIGURE 112–41**.



STABILIZER BAR LINK
STABILIZER BAR

FIGURE 112–41 Stabilizer bar links should be replaced as a pair.

Stabilizer links are replaced by unbolting the old parts and installing replacement parts. Special precautions are usually not necessary, but, as always, consult a service manual for the exact recommended procedure and fastener torque.

If the mounting bushings (also called isolator bushings) on the body or frame are worn or defective, a loud squeaking or knocking sound is usually heard.

Stabilizer bar bushings often fail because the rubber has deteriorated from engine oil or other fluid leaks. Before replacing defective bushings, make certain that all other fluid leaks are stopped. Stabilizer bar bushing replacement involves the removal (unbolting) of the bushing retainers that surround the bushing and attach to the vehicle body or frame. The bushings are usually split so that they can be easily removed and replaced on the stabilizer bar and can slide into proper position. Reinstall the bushing retainer bolts and tighten to the specified torque.

STRUT ROD BUSHINGS

DIAGNOSIS Strut rods are used on the front suspension of many front-wheel-drive and rear-wheel-drive vehicles. As with any rubber suspension component, strut rod bushings can deteriorate and crack. When strut rod bushings fail, the lower control arm can move forward and backward during braking or when hitting bumps in the road.

Since the lower control arm position is important to vehicle control, when the bushing fails, a pulling or drifting of the vehicle often occurs. *A common symptom of a defective strut rod bushing is noise and a pull toward one side while braking*.

REPLACEMENT To replace a strut rod bushing, the nut on the end of the strut rod has to be removed. ● **SEE FIGURE 112–42.** As the nut is being removed, the lower control arm is likely to move forward or backward, depending on the location of the strut rod frame mount. After removing the strut rod nut, remove the one or two fasteners that retain the strut rod to the lower control arm. The strut rod can now be removed from the vehicle and the replacement rubber bushings can be installed. Install the strut rod in the reverse order of installation. Most bushings use a serrated spacer to maintain the proper force on the rubber bushings; this prevents the technician from compressing the rubber bushing when the strut rod nut is tightened. ● **SEE FIGURE 112–43.**

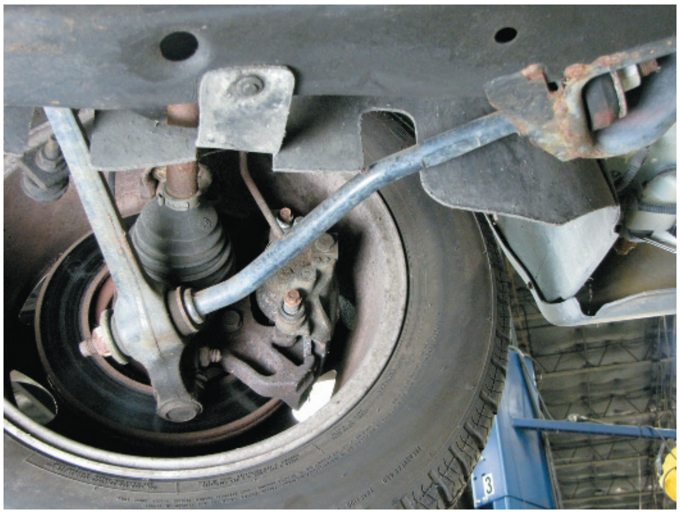


FIGURE 112–42 A strut rod as viewed from the front of the vehicle.

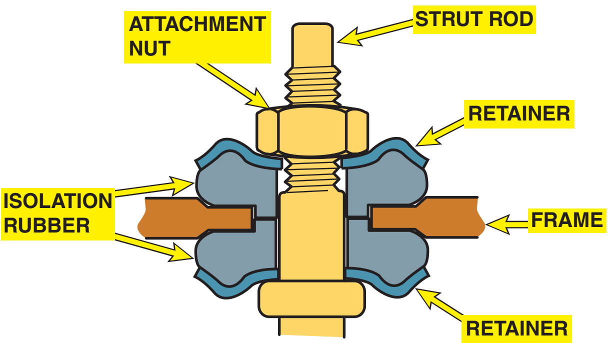

FIGURE 112–43 Typical strut rod bushing with rubber on both sides of the frame to help isolate noise, vibration, and harshness from being transferred to the passengers.

CAUTION: Some suspension bushings are directional and must be installed according to the vehicle manufacturer's instructions. For example, on some vehicles, the bushings have a slit or void, which must face the front of the vehicle. Always check service information when installing new bushings.

FRONT COIL SPRINGS

DIAGNOSIS Coil springs should be replaced in pairs if the vehicle ride height is lower than specifications. Sagging springs can cause the tires to slide laterally (side to side) across the pavement, causing excessive tire wear. ● **SEE FIGURE 112–44.** Sagging springs can also cause the vehicle to bottom out against the suspension bumpers when traveling over normal bumps and dips in the road.

FIGURE 112–44 Notice that if the front coil springs are sagging, the resulting angle of the lower control arm causes the wheels to move from side to side as the suspension moves up and down. Note the difference between the distance at "A" with good springs and the distance at "B" with sagging springs.

If a vehicle is overloaded, the springs of the vehicle can *take a set* and not recover to the proper ride height. This commonly occurs with all types of vehicles whenever a heavy load is carried, even on a short trip.

It is normal for the rear of a vehicle to sag when a heavy load is carried, but it can permanently damage the spring by exceeding the yield point of the steel spring material.

REPLACEMENT The only solution recommended by the vehicle manufacturer is to replace the damaged springs in pairs (both front and both rear, or all four). Several aftermarket alternatives include the following:

- **Helper or auxiliary left springs.** These helper springs are usually designed to increase the load-carrying capacity of leaf springs or to restore the original ride height to sagging springs.
- **Spring inserts for coil springs.** Hard rubber or metal spacers are *not recommended* because they create concentrated pressure points on the coils that can cause the spring to break. Hard rubber stabilizers that bridge the gap between two coils without raising the ride height stiffen the ride by locking two coils together. With two coils connected, the spring rate increases and the spring becomes stiffer.
- **Air shocks or airbag devices.** Air shocks or airbags are generally used to restore or increase the load-carrying capacity to the rear of the vehicle. While these devices do allow the ride height to be maintained, the extra load is still being supported by the tires and rear axle bearings. Caution should be used not to overload the basic chassis or power train of the vehicle.

There are two designs for vehicles that use coil springs. The most commonly used design places the coil spring between the vehicle frame and the lower control arm.

Both front-suspension designs require that the front shock absorbers be removed in order to replace the coil springs. This first step in the coil spring removal procedure can be performed on the ground or on any type of hoist. After removing the shock absorber, use a coil spring compressor and install it through the center of the coil spring. ● **SEE FIGURE 112–45**. Hook the arms of the coil spring compressor over the rungs of the coil spring and rotate the adjusting nut on the spring compressor with a wrench to shorten the spring. Coil spring clips can also be used to retain the coil spring.

CAUTION: When compressed, all springs contain a great deal of stored energy. If a compressed spring were to become disconnected from its spring compressor or clips, it could be projected outward with enough force to cause injury or death.

After the coil spring is retained, the control arm can be separated from the steering knuckle and the coil spring can be removed as shown in ● **FIGURES 112–46 AND 112–47**.

Replacement springs should be compressed and installed using the reverse procedure.

NOTE: Many automotive experts recommend that new coil insulators be installed every time the coil springs are replaced.

Make sure that the spring is positioned correctly in the control arm and that the spring insulators are installed correctly. ● **SEE FIGURE 112–48**. Most control arms use two holes for the

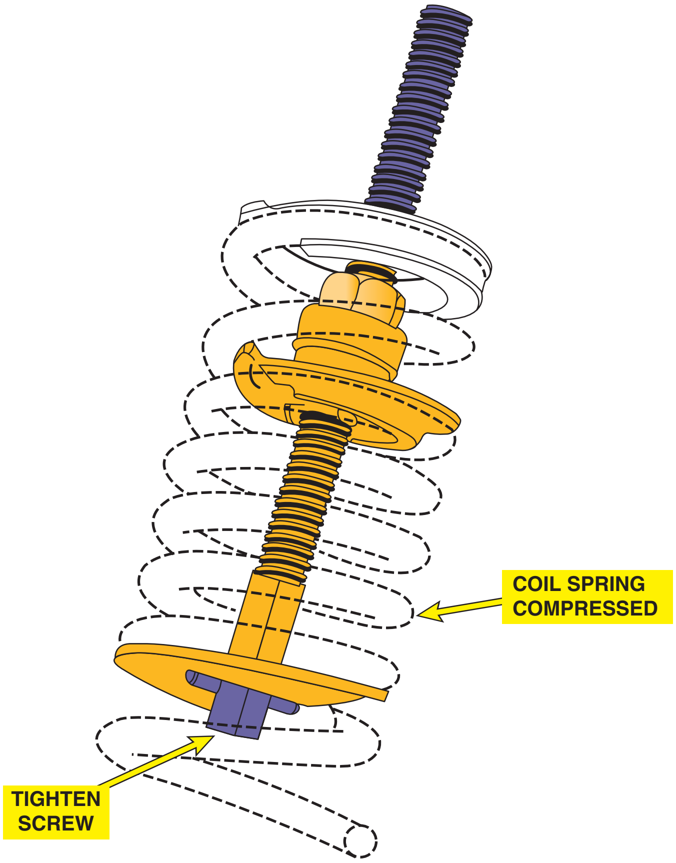

FIGURE 112–45 A spring compressor is required by most vehicle manufacturers to be used whenever disassembling a coil spring suspension system.

CASE STUDY

The Rock-Hard Problem

The owner of a six-month-old full-size pickup truck complained that occasionally when the truck was driven up into a driveway, a loud grinding sound was heard. Several service technicians worked on the truck, trying to find the cause for the noise. After the left front shock absorber was replaced, the noise did not occur for two weeks and then started again. Finally, the service manager told the technician to replace anything and everything in the front suspension in an attempt to solve the customer's intermittent problem. Five minutes later, a technician handed the service manager a small, deformed rock. This technician had taken a few minutes to carefully inspect the entire front suspension. Around the bottom coil spring seat, the technician found the rock. Apparently, when the truck made a turn over a bump, the rock was forced between the coils of the coil spring, making a very loud grinding noise. But the rock did not always get between the coils. Therefore, the problem occurred only once in a while. The technician handed the rock to the very happy customer.

Summary:

Complaint—Vehicle owner complained of loud grinding sound from the front suspension at times.
Cause—A rock was found at the bottom of the coil spring seat.
Correction—The rock was removed.

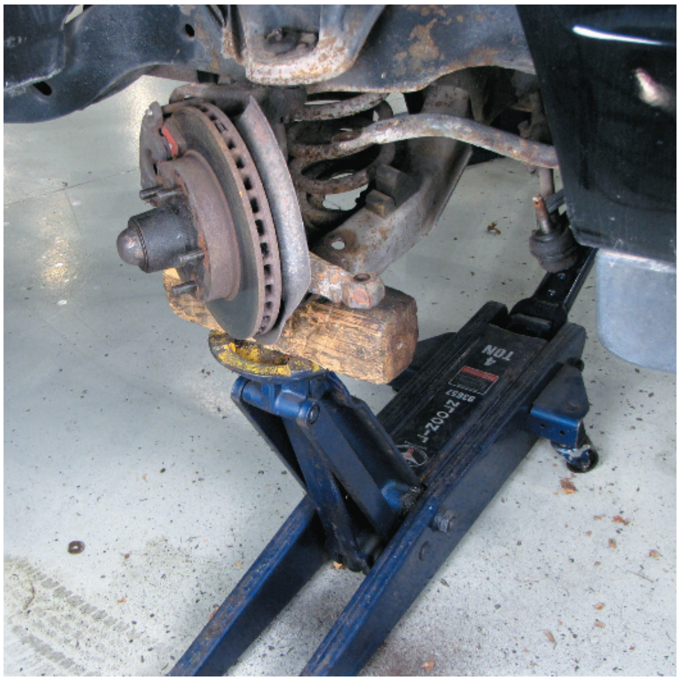

FIGURE 112–46 The steering knuckle has been disconnected from the lower ball joint. The lower control arm and the coil spring are being held up by a floor jack.

purpose of coil spring seating. The end of the spring should cover one hole completely and partially cover the second hole. ● **SEE FIGURE 112–49**.

STEERING KNUCKLES

DIAGNOSIS Most steering knuckles are constructed of cast or forged cast iron. The steering knuckle usually incorporates the wheel spindle and steering arm. The steering knuckle/steering arm can become bent if the vehicle is in an accident or hits a curb sideways. Often this type of damage is not apparent until vehicle handling or excessive tire wear is noticed. Unless a thorough inspection is performed during a wheel alignment, a bent steering knuckle is often overlooked.

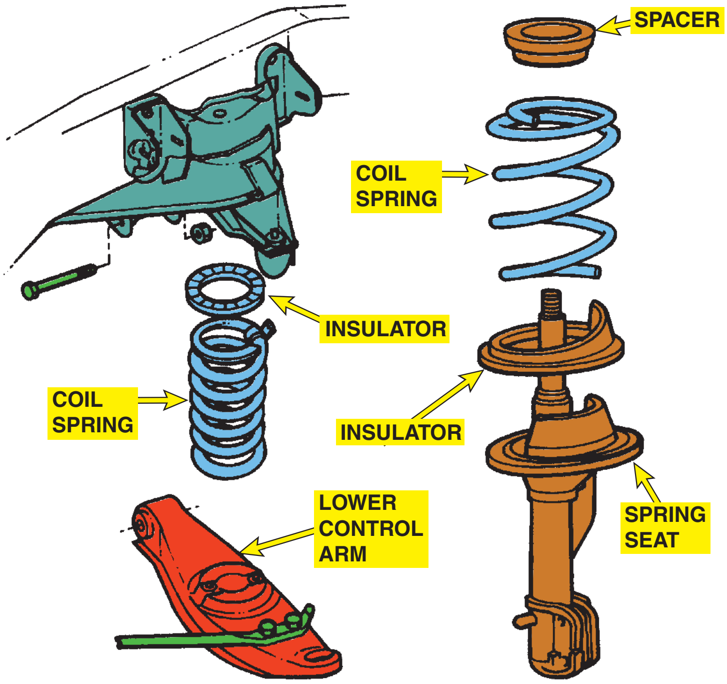

FIGURE 112–48 Spring insulators are installed between the spring seat and the coil spring to reduce noise.

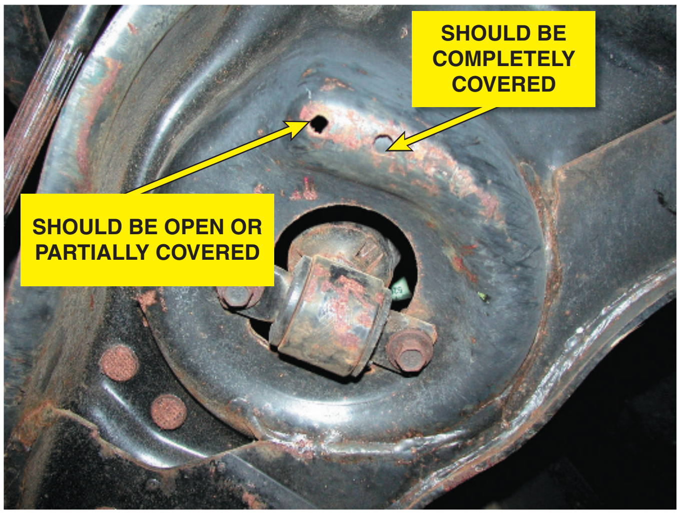

SHOULD BE COMPLETELY COVERED
SHOULD BE OPEN OR PARTIALLY COVERED

FIGURE 112–49 The holes in the lower arm are not only used to allow water to drain from the spring seat, but also used as a gauge to show the service technician that the coil spring is correctly seated.

REPLACEMENT If the steering knuckle is bent or damaged, it must be replaced. It should *not* be bent back into shape or repaired. To replace the steering knuckle, both ball joints must be disconnected from the knuckle and the brake components removed. Be sure to support the control arm and spring properly during the procedure. See a factory service manual for the exact procedure and fastener torque for the vehicle you are servicing.

TORSION BARS

ADJUSTMENT Most torsion bar suspensions are designed with an adjustable bolt to permit the tension on the torsion bar to be increased or decreased to change the ride height. Unequal side-to-side ride height can be corrected by adjusting (turning) the torsion bar tension bolt. ● **SEE FIGURE 112–50**.

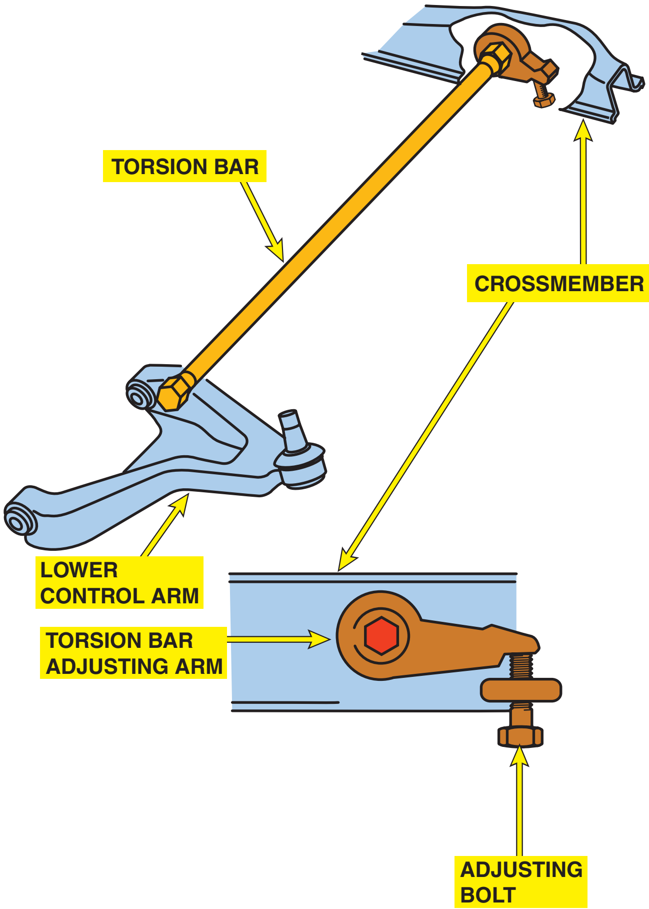

FIGURE 112–50 By rotating the adjusting bolt, the vehicle can be raised or lowered.

Torsion bar adjustment should be made if the difference in ride height from one side to another exceeds 1/8 inch (0.125 inch or 3.2 mm). If the ride height difference side to side is greater than 1/8 inch, the vehicle will tend to wander or be unstable, with constant steering wheel movements required to maintain a straight-ahead direction.

NOTE: Torsion bars should never be switched from one side of the vehicle to the other as they are twisted and work hardened in one direction and can break if installed on the opposite side of the vehicle.

CONTROL ARM BUSHINGS

DIAGNOSIS Defective control arm bushings are a common source of vehicle handling and suspension noise problems. Most suspension control arm bushings are constructed of three parts: an inner metal sleeve, the rubber bushing itself, and an outer steel sleeve. (Some vehicles use a two-piece bushing that does not use an outer sleeve.)

REPLACEMENT To remove an old bushing from a control arm, the control arm must first be separated from the suspension and/or frame of the vehicle. Several methods can be used to remove the bushing from the control arm, but all methods apply force to the *outer* sleeve. While an air chisel is frequently used to force the steel sleeve out of the suspension member, a puller tool is most often recommended by General Motors. ● **SEE FIGURE 112–51**. The puller can be used to remove the old bushing and install the replacement bushing without harming the control arm or the new bushing. All bushings should be tightened with the vehicle on the ground and the wheels in a straight-ahead position; this prevents the rubber bushing from exerting a pulling force on the suspension.

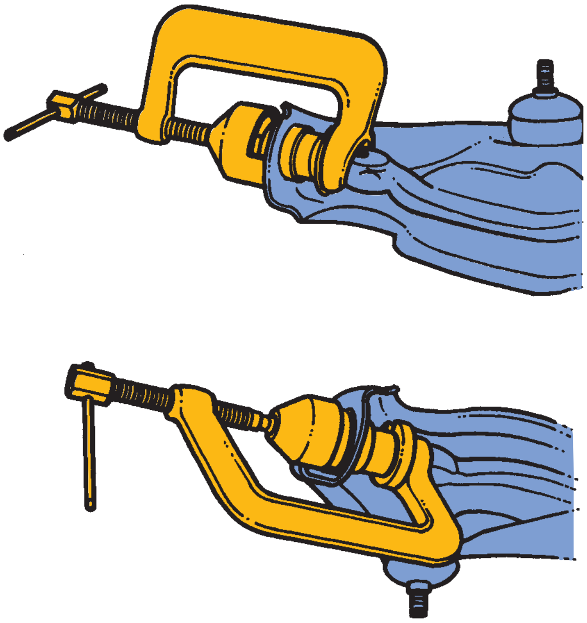

FIGURE 112–51 An adapter and a press or large clamp are used to remove the old bushing from the control arm and to install a new bushing.

NOTE: Some replacement control arm bushings have a higher durometer, or hardness, rating than the original. Urethane bushings are often used in sporty or race-type vehicles and deflect less than standard replacement bushings. These harder bushings also transfer more road noise, vibration, and harshness to the body.

The upper control arm bushings can be replaced in most vehicles that use a short-/long-arm-type suspension by following just four easy steps:

STEP 1 Raise the vehicle and support the lower control arm with a safety stand or floor jack.

STEP 2 Disconnect the upper control arm from the frame by removing the frame-attaching nuts or bolts.

STEP 3 Using the upper ball joint as a pivot, rotate the upper control arm outward into the wheel well area. With the control arm accessible, it is much easier to remove and replace the upper control arm pivot shaft and rubber bushings.

STEP 4 After replacing the bushings, simply rotate the upper control arm back into location and reattach the upper control arm pivot shaft to the vehicle frame.

NOTE: An alignment should always be performed after making any suspension-related repairs.

STRUT REPLACEMENT

STEP BY STEP

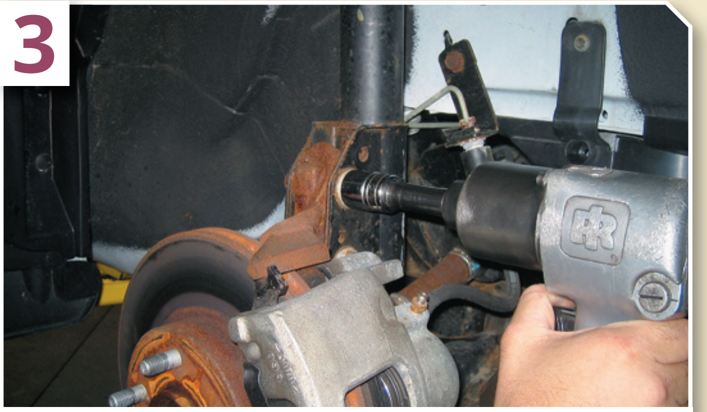
1

The tools needed to replace a front strut assembly include several sockets and a ball-peen hammer, plus a strut compressor.

2

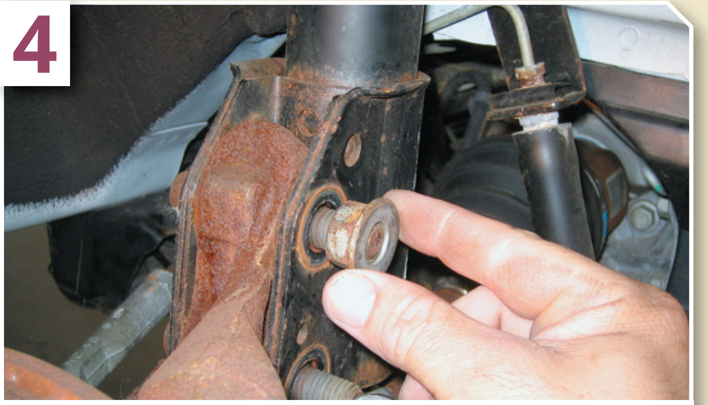
After safely hoisting the vehicle to elbow height and removing the wheel covers, remove the front tire/wheel assembly.

3



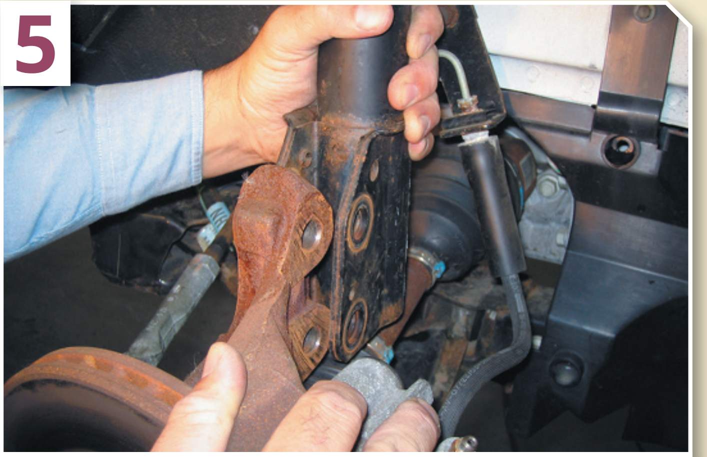
Remove the two strut retaining nuts.

4



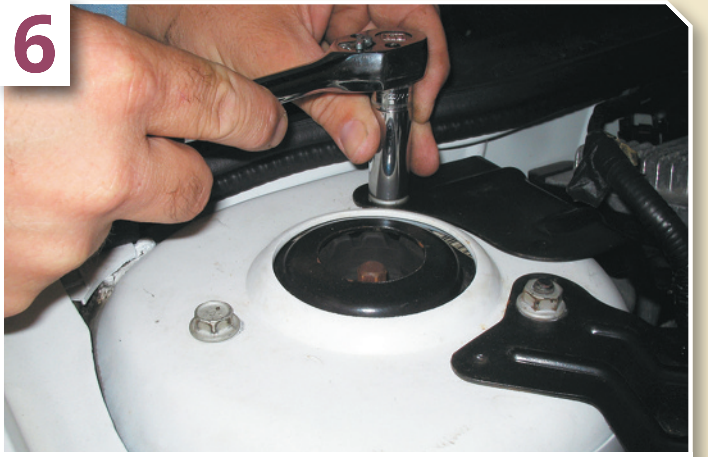
Before using a hammer to drive the retaining bolts from the steering knuckle, thread the nut into the bolt backward to prevent causing damage to the threads.

5



Remove the retaining bolts and separate the strut from the steering knuckle.

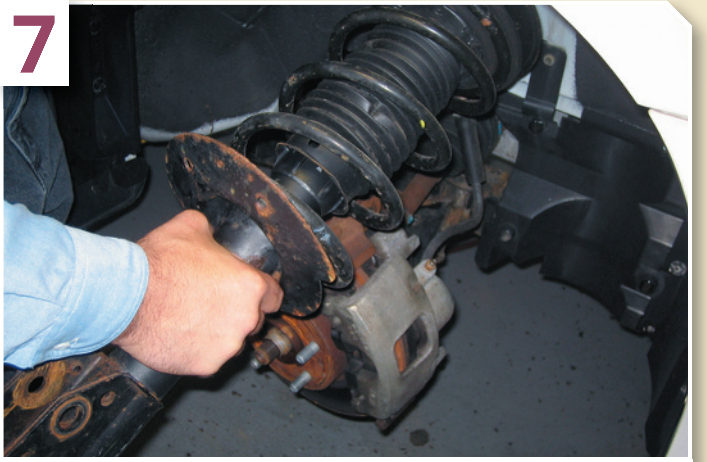
6



Lower the vehicle and remove the upper strut retaining fasteners.

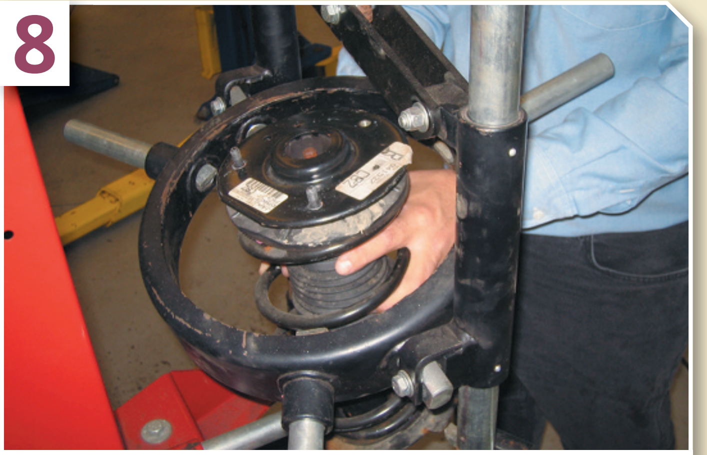
STRUT REPLACEMENT

7



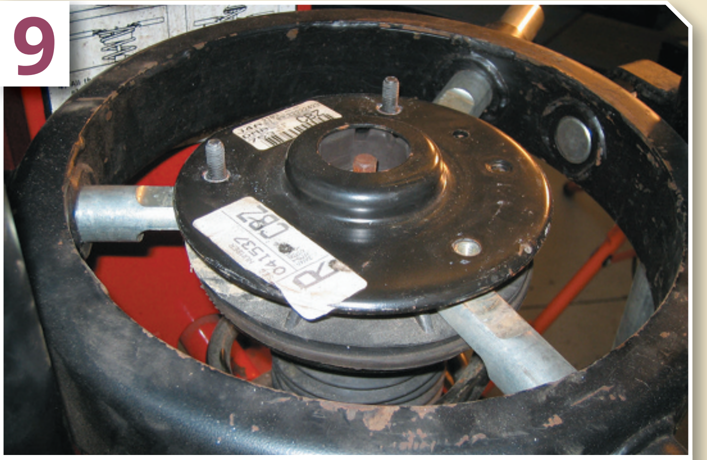
Hold the strut while removing the last upper retaining nut and then remove the strut assembly.

8



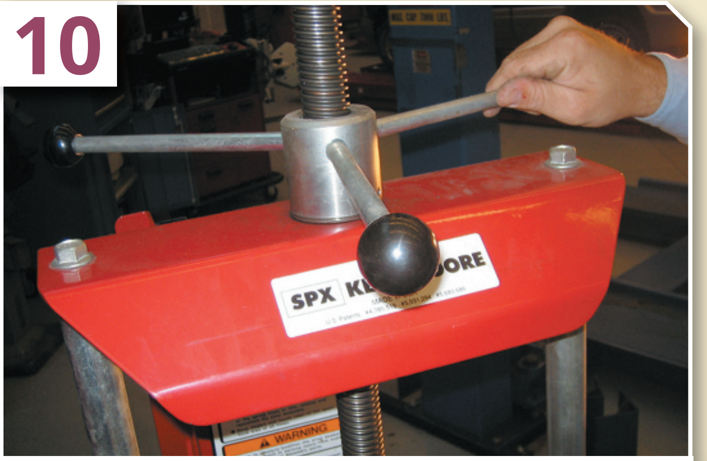
After the strut has been removed from the vehicle, install the assembly into a strut compressor.

9



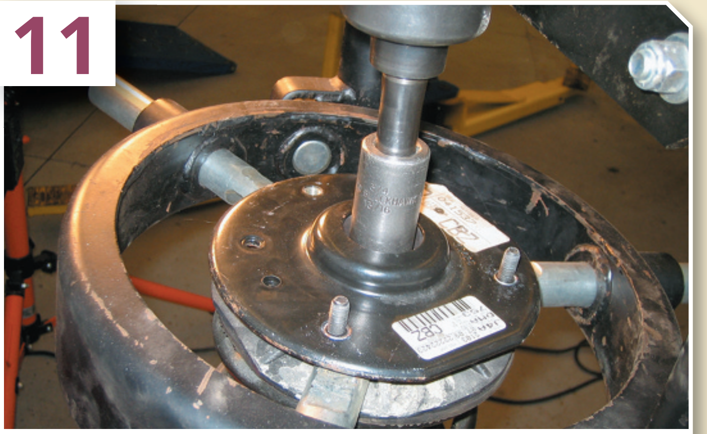
Position the jaws of the compressor under the bearing assembly as per the vehicle manufacturer's instructions.

10



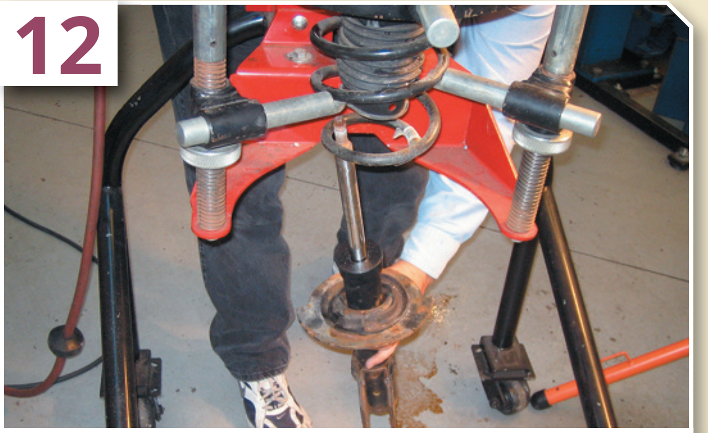
Turn the compressor wheel until all tension of the spring has been relieved from the upper bearing assembly.

11



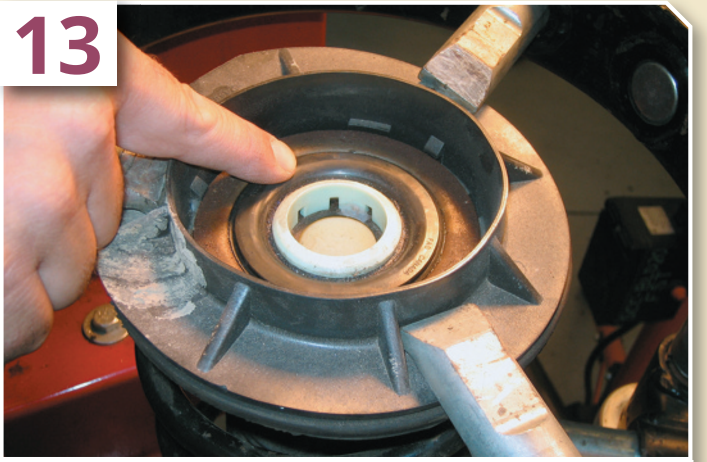
Remove the strut retaining nut.

12



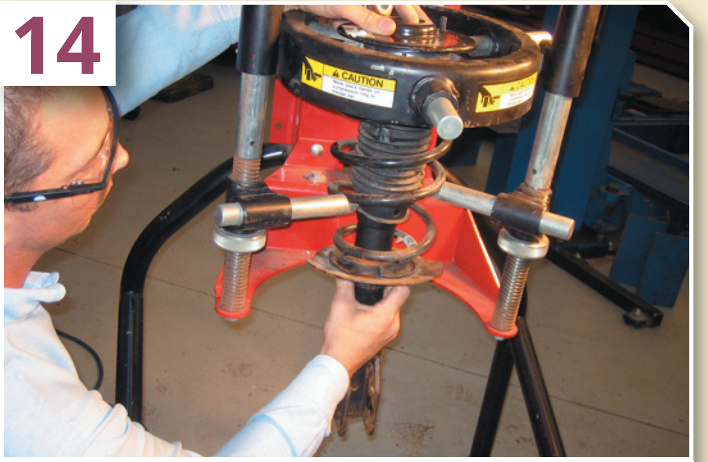
Remove the strut assembly.

13



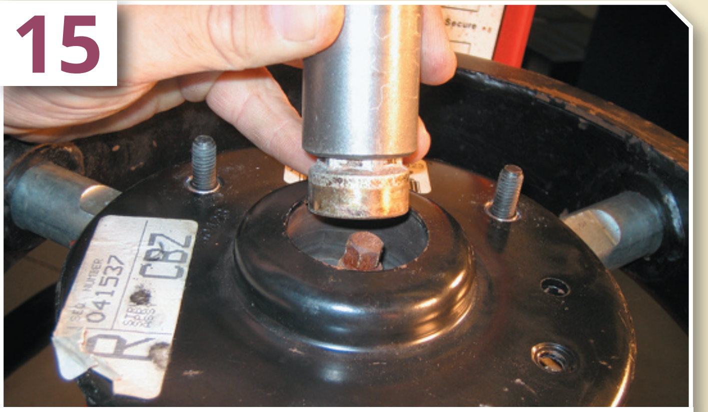
Before installing the replacement strut, check the upper bearing by exerting a downward force on the bearing while rotating and check for roughness. Replace if necessary.

14



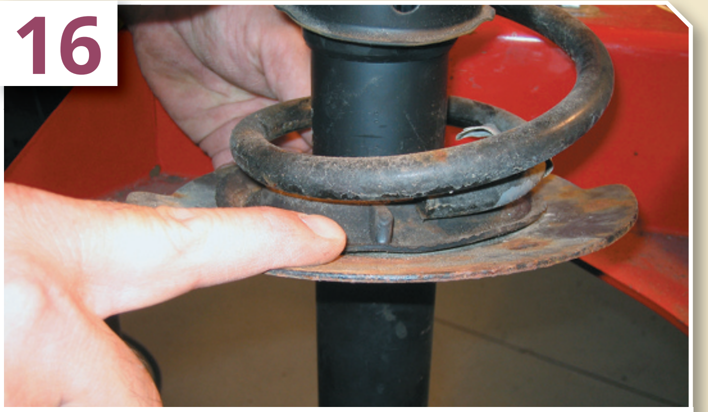
Install the strut from underneath the spring compressor fixture.

15



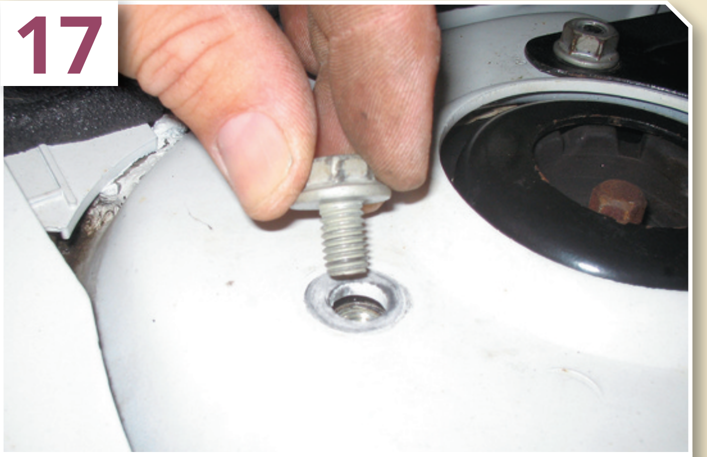
Install the strut retaining nut. Most vehicle manufacturers specify that the strut retaining nut be replaced and the old one discarded.

16



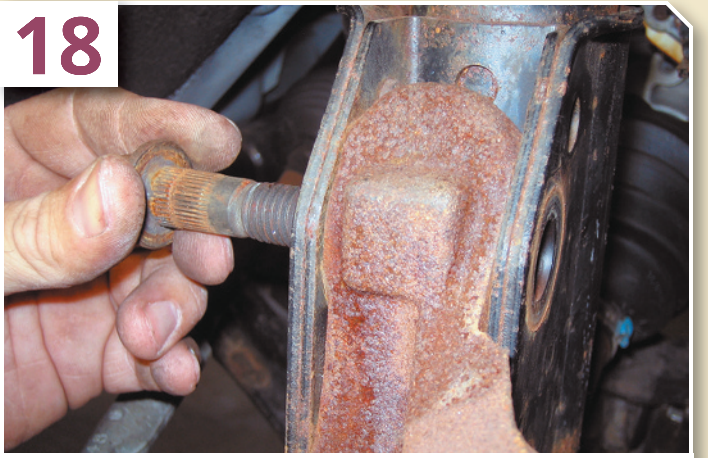
Before loosening the tension, check that the coil spring is correctly located at both the top and the bottom, then release the tension on the spring.

17



Remove the strut assembly from the compressor and back of the vehicle and install the upper fasteners. Do not torque to specifications until the lower fasteners have been installed.

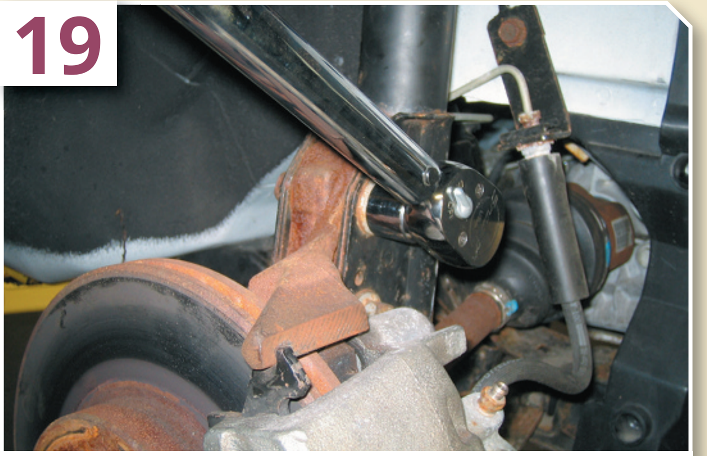
18



Attach the lower strut to the steering knuckle using the original hardened bolts and nuts.

STRUT REPLACEMENT

19



Using a torque wrench, torque all fasteners to factory specifications.

20

Install the tire/wheel assembly, lower the vehicle, and torque the lug nuts to factory specifications. Align the vehicle before returning it to the customer.

REAR SUSPENSION AND SERVICE

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Describe solid rear axles.
- Describe leaf spring rear suspensions.
- Distinguish between trailing arm and semi-trailing arm rear suspensions.
- Distinguish between independent and semi-independent rear suspensions.
- Explain rear suspension service.
- Describe replacement of rear shocks.
- Describe replacement of rear springs.

KEY TERMS:

Axle windup 1393 • Chapman strut 1395 • Hotchkiss drive 1393 • IRS 1395 • Live axle 1393 • Panhard rod 1394 • Semi-independent suspension 1395 • Semi-trailing arm 1395 • Solid axle 1392 • Torque arm 1394 • Track rod 1394 • Trailing arm 1393 • Watts linkage 1395

SOLID REAR AXLES

All suspensions have two basic jobs: keeping the tires on the ground and providing a smooth ride. A **solid axle** can be used at the rear of either a rear-wheel-drive or front-wheel-drive vehicle. ● **SEE FIGURE 113–1**. On a rear-wheel-drive vehicle, a solid rear axle consists of the differential gears and axle shafts inside a solid housing. On a front-wheel-drive vehicle, a solid axle is usually a simple U-shaped or tubular beam that may contain a torsion bar, rod, or tube to allow some twisting action.

Certain characteristics apply to any solid rear axle, while other characteristics vary by the type of suspension used to attach the axle to the frame.

Solid axles have some handling characteristics that are inferior to those of an independent suspension. Disadvantages of a solid axle include the following:

- Increased proportion of unsprung weight
- Side-to-side road shock transference
- Poorer tire adhesion

Increasing the proportion of unsprung weight decreases ride quality. Transferring road shock from side to side causes wheel tramp and shimmy, and poor tire adhesion accelerates tire wear. ● **SEE FIGURE 113–2**.

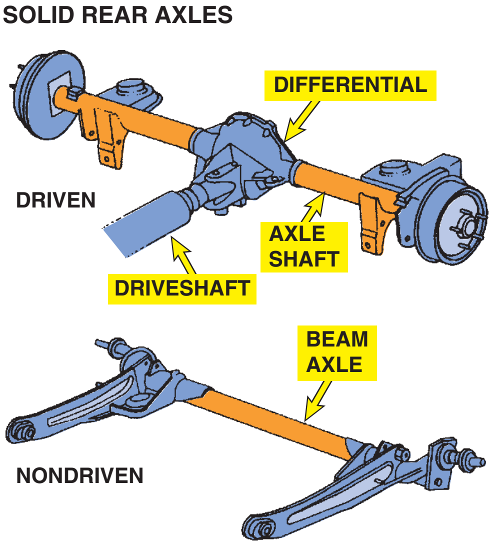

FIGURE 113–1 Solid axles are used on rear-wheel-drive vehicles as well as on front-wheel-drive vehicles.

The sprung weight of the frame and body must be heavy to oppose the unsprung weight of a solid axle, especially on a driven axle. Unsprung weight, wheel tramp, and shimmy all reduce tire adhesion. The effects of these problems are more

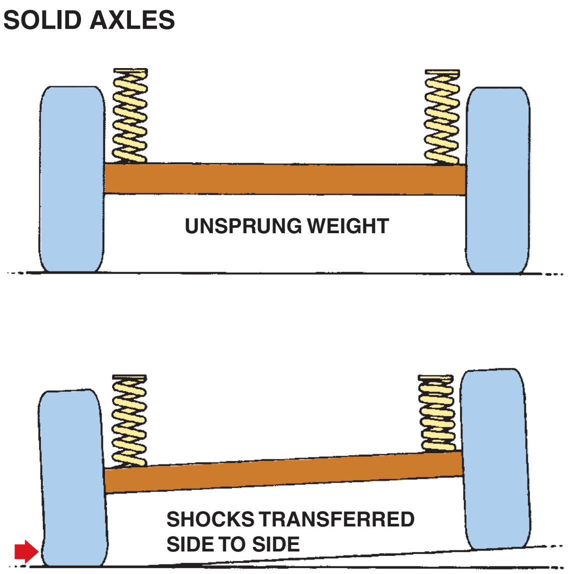

FIGURE 113–2 A solid axle supports the springs, so the axle and suspension components are unsprung weight. When one wheel rides over a bump, the force of impact transfers through the solid axle to the opposite side, leading to unstable handling.

noticeable in rear-wheel-drive vehicles due to the weight of the rear axle and differential assembly. On a typical front-wheel-drive vehicle, the simple axle beam is not heavy enough to decrease ride quality or cause extreme tire wear. In fact, the rear tires of a front-wheel-drive model always wear more slowly than the front tires because the rear axle is so much lighter than the power train.

If engine torque is applied to the rear axle to drive the vehicle, the axle is referred to as a **live axle**.

LEAF SPRING REAR SUSPENSIONS

A leaf spring suspension is a simple system because it does not require control arms to brace and position the axle. The leaf springs link the axle to the frame and effectively serve two purposes:

- Absorbing road shock
- Locating the axle under the vehicle

FREQUENTLY ASKED QUESTION

What Is Axle Windup?

Axle windup is a product of the law of physics, which states that every action produces an equal and opposite reaction. As the axle shafts rotate in one direction to drive the wheels, the axle housing attempts to rotate in the opposite direction. The force of this reaction tends to lift the front end of the vehicle during acceleration. ● **SEE FIGURE 113–3**. Axle windup is a particular problem with a solid, driven rear axle because the axle housing concentrates the reacting force. Under extreme acceleration, the reacting force can actually tilt the drive shaft upward and lift the front wheels off the ground. Leaf springs, control arms, pinion snubbers, and torque arms all are means of controlling axle windup.

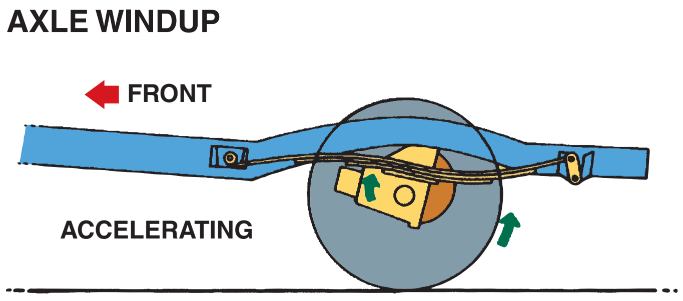

FIGURE 113–3 When the axle housing reacts against the force of axle shaft rotation, the front of the differential tilts upward, creating axle windup.

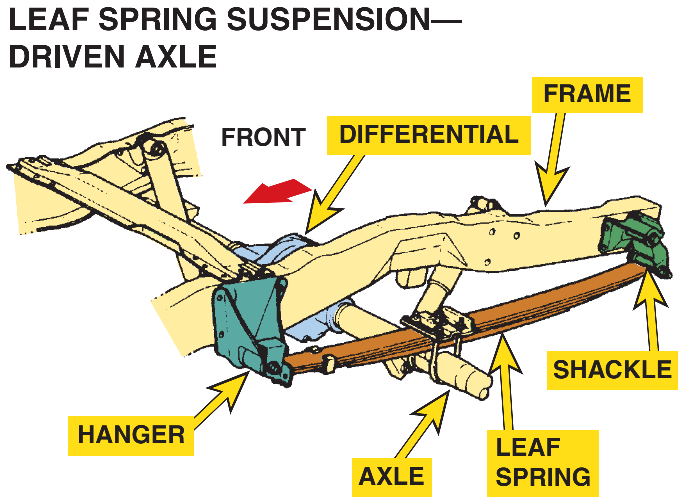

FIGURE 113–4 A typical rear-wheel-drive pickup truck rear suspension equipped with leaf springs. This type of arrangement is called a Hotchkiss drive and the drivetrain forces are controlled by the rear suspension components.

Most rear-wheel-drive trucks use a solid rear axle with leaf springs in an arrangement called a **Hotchkiss drive**. ● **SEE FIGURE 113–4**. Leaf springs on a driven axle control axle windup by transferring force from the axle housing to the frame. The front portion of the leaf spring, from the axle housing to the frame mount, acts like a trailing control arm. However, if the front section of the leaf spring is too flexible, it may not control axle windup as well. To compensate, some manufacturers make the front section of the spring shorter, and therefore less flexible, than the rear section.

Leaf springs are used on the rear of many light- and medium-duty trucks and vans. ● **SEE FIGURE 113–5**. The wheel spindles bolt to the flanges, the centers of the leaf springs rest on the seats, and U-bolts secure the springs to the axle. A shackle attaches the rear of each spring to the unit-body frame, while the front of each spring pivots through a bolt and bushing connected to a hanger that bolts to the body.

TRAILING ARM AND SEMI-TRAILING ARM REAR SUSPENSIONS

TRAILING ARM REAR SUSPENSIONS A **trailing arm** extends from a frame crossmember located ahead of the rear axle back to the axle housing or a wheel knuckle. Trailing arms run parallel

to the centerline of the chassis. ● **SEE FIGURE 113–6**. A trailing arm mounts to the frame with bushings, which allow the arm to pivot as the wheel rides over bumps. Some rear suspensions use two sets of trailing arms, one set positioned higher in the chassis than the other. Although the arms in this type of arrangement are commonly referred to as the *upper control arms* and *lower control arms*, they are usually called trailing arms. The word *trailing* applies to any link where the supported member trails the arm. Trailing arms may be used to brace either a driven or nondriven solid rear axle against front-to-rear forces, but they do not provide much resistance to side-to-side, or lateral, forces. The axle itself is one means of locating the wheels side-to-side, and solid rear suspensions frequently use another rod to provide additional support. Trailing arms transfer axle windup force to the frame and control front-to-rear axle movement. On a few models, especially those with a high-performance suspension, a **torque arm** provides additional resistance to axle windup. ● **SEE FIGURE 113–7**. The torque arm extends parallel to the drive shaft between the rear axle and the transmission. One end of the torque arm is rigidly bolted to the differential housing, while the other end attaches to the transmission through a cushioned bracket to allow some flex.

A trailing arm rear suspension on a nondriven solid axle virtually always includes a **track rod**, also called a **Panhard rod**. A track rod is a rod attached to the body or frame on one end and the rear axle on the other. The purpose of the track rod is to keep the rear axle centered under the vehicle. The suspension may use either coil springs or struts.

The rear axle is a U-shaped steel beam that is open on the bottom. ● **SEE FIGURE 113–8**. Flat metal axle end plates, to which the wheel spindles bolt, are attached to each end of the beam. A torsion tube or rod fits inside the beam and is welded to the axle end plates.

The trailing arms, which are welded to the outboard ends of the axle, extend forward and attach to the frame with pivot

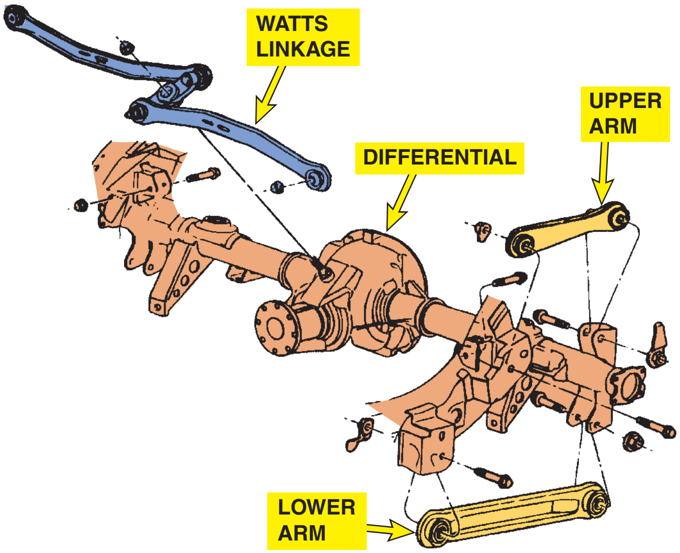

FIGURE 113–9 This Ford rear suspension uses upper and lower semi-trailing arms to mount the rear axle and a watts linkage to control side-to-side movement.

bushing mounts. A bracket on top of the beam axle locates the ring-type lower strut mount, and the upper strut mount attaches to a reinforced area of the wheel well.

SEMI-TRAILING ARM REAR SUSPENSIONS A **semi-trailing arm** is similar to a trailing arm in that it extends back from a frame member to the axle. However, a trailing arm is parallel to the vehicle centerline whereas a semi-trailing arm pivots at an angle to the vehicle centerline. Semi-trailing arms have an advantage over trailing arms because they control both side-to-side and front-to-rear motion. Typically, a semi-trailing arm suspension uses coil springs, air springs, or pivot-base struts.

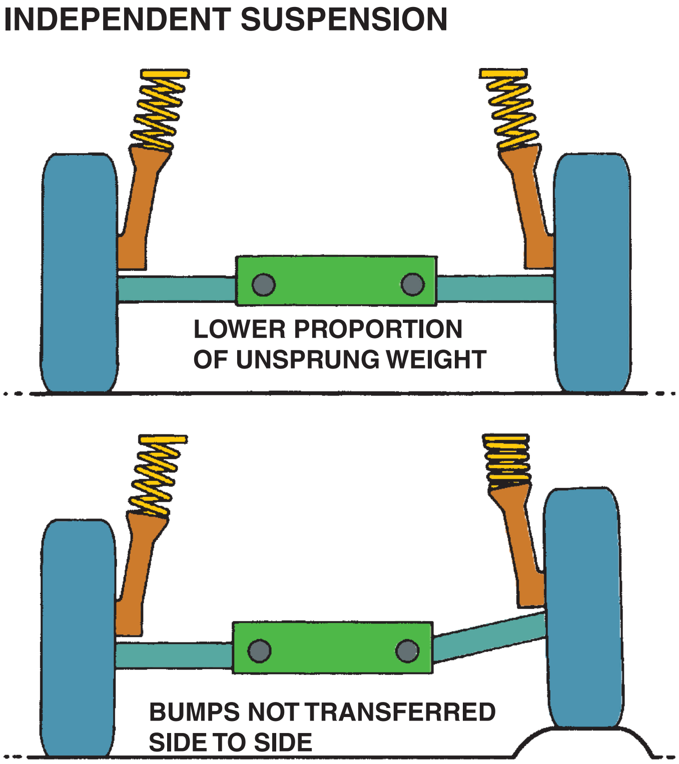
A semi-trailing arm suspension may be used with either a solid axle or an independent suspension.

The Ford suspension uses two pairs, upper and lower, of semi-trailing arms and a center pivot arrangement to locate the driven rear axle. This axle centering pivot bracket and linkage is called a **watts linkage**. ● **SEE FIGURE 113–9**.

INDEPENDENT AND SEMI-INDEPENDENT REAR SUSPENSIONS

INDEPENDENT REAR SUSPENSIONS The use of **independent rear suspension**, called **IRS**, has grown dramatically over the past several decades to the point where such systems are now fairly common, especially on front-wheel-drive vehicles and some rear-wheel-drive vehicles. Although rarely used on trucks, a number of rear-wheel-drive vehicles do feature an independent rear suspension.

The reduction in unsprung weight is particularly noticeable for driven axles, which are constructed to transfer the weight of the differential and axles to the frame. ● **SEE FIGURE 113–10**. A vehicle with an independent rear suspension rides and handles better than a similar vehicle equipped with a solid rear axle. An SLA-type of independent suspension may be used at the rear of a rear-wheel-drive vehicle. ● **SEE FIGURE 113–11**.



INDEPENDENT SUSPENSION
LOWER PROPORTION OF UNSPRUNG WEIGHT
BUMPS NOT TRANSFERRED SIDE TO SIDE

FIGURE 113–10 An independent rear suspension provides a better ride because less weight is unsprung and the suspension is able to react quickly to bumps in the road without affecting the opposite side.

The differential carrier bolts to the rear subframe, which bears the weight of the axle. Equal-length axle shafts with constant-velocity (CV) joints at either end connect the differential to the rear wheels and allow the wheels to move independently of each other.

The main benefit of an SLA suspension is that it reduces tire scrub and improves traction. The positioning of the control arms determines the suspension roll center location. In general, the lower the roll center, the less body roll.

Unit-body front-wheel-drive vehicles frequently use strut suspensions at the rear axle. Typically, the strut mounts to the knuckle and replaces the upper control arm. The first designer to put MacPherson-type struts in a rear suspension was an Englishman, Colin Chapman. For this reason, a rear strut suspension is often referred to as a **Chapman strut** suspension by European manufacturers and engineers.

The MacPherson strut system is the most popular independent rear suspension for late-model front-wheel-drive vehicles. ● **SEE FIGURE 113–12**. Modified strut rear suspensions are found on a variety of front-wheel-drive models from different manufacturers. ● **SEE FIGURE 113–13**.

General Motors produced two different rear modified strut systems with transverse leaf springs. ● **SEE FIGURE 113–14**. A transverse leaf spring is also used on the Chevrolet Corvette and the Cadillac XLR.

SEMI-INDEPENDENT REAR SUSPENSIONS A **semi-independent suspension** is used only at a nondriven rear axle. The semi-independent design is based on a crossbeam that is similar to the beam axle of a solid, nondriven rear suspension. However, on a semi-independent design, the crossbeam is placed ahead, rather than at the centerline, of the wheels. ● **SEE FIGURE 113–15**. Trailing arms extend rearward from the

Some semi-independent rear suspensions use struts. ● **SEE FIGURE 113–16**.

REAR SUSPENSION SERVICE

Rear suspension service starts with a thorough test-drive, to observe any unusual noises or vibrations that may be caused by a fault with a rear suspension component.

After a test-drive, safely hoist the vehicle and perform a thorough visual inspection. Use an appropriate prybar and move all of the bushings and joints, checking for deterioration or freeplay. ● **SEE FIGURE 113–17**.

Inspect the shock absorber or struts for leakage or damage. Inspect the bump stops for damage. ● **SEE FIGURE 113–18**. If the bump stops are damaged, this may indicate that the springs are fatigued and the vehicle is at lower-than-normal ride height, or that the shocks or studs are unable to control the springs. ● **SEE FIGURE 113–19**.

REAR SHOCK REPLACEMENT

PRECAUTIONS Before removing the rear shock absorbers, the rear axle must be supported to prevent stretching of the rear brake flexible hose. Shocks are attached to the frame or body of the vehicle at the top and to a bracket on the rear axle housing at the bottom. Often, the top of the rear shock absorber is fastened *inside* the vehicle. Consult the vehicle manufacturer's service information for exact procedures and fastener torque values.

NOTE: Shock absorbers and/or struts should always be replaced as a pair.

AIR SHOCK INSTALLATION Air-adjustable shock absorbers are a popular replacement for conventional rear shock absorbers. Air shocks can be used to level the vehicle while towing a trailer or when heavily loaded. When the trailer or load is removed, air can be released from the air shocks to return the vehicle height to normal.

Most replacement air shocks are directional and are labeled *left* and *right*. This ensures that the plastic air hose line exits the shock absorber toward the center or rear of the vehicle and is kept away from the wheels.

The plastic air shock line attaches to the shock absorber with an O-ring or brass ferrule and nut. An air leak can result if this O-ring or ferrule is not installed according to the manufacturer's recommendations. Route the plastic air line along the body, keeping it away from the exhaust and any other body parts where the line could be damaged. Attach the line to both shocks to a junction at a convenient location for adding or releasing air.

REAR SPRING REPLACEMENT

REAR COIL SPRINGS

REPLACEMENT Coil springs in the rear are easily replaced on both front-wheel-drive and rear-wheel-drive vehicles. The procedure includes the following steps:

1. Raise the vehicle safely on a hoist.
2. Remove both rear wheels.
3. Support the rear axle assembly with tall safety stands.
4. Remove the lower shock absorber mounting bolts/nuts and disconnect the shock absorber from the rear axle assembly.
5. Slowly lower the rear axle assembly by either lowering the height of the adjustable safety stands or raising the height of the vehicle on the hoist.
6. Lower the rear axle just enough to remove the coil springs. ● **SEE FIGURE 113–21.**

CAUTION: The shock absorber is usually the only component that limits the downward movement of the rear axle to allow removal of the rear coil springs. Some vehicles may be equipped with rear suspension height sensors for the adjustable suspension system or an adjustable rear proportioning valve for the rear brakes. Some vehicles also require that the rear stabilizer bar or track rod be disconnected or removed before lowering the rear axle assembly. Always consult service information for the exact procedure and torque specifications for the vehicle being serviced.

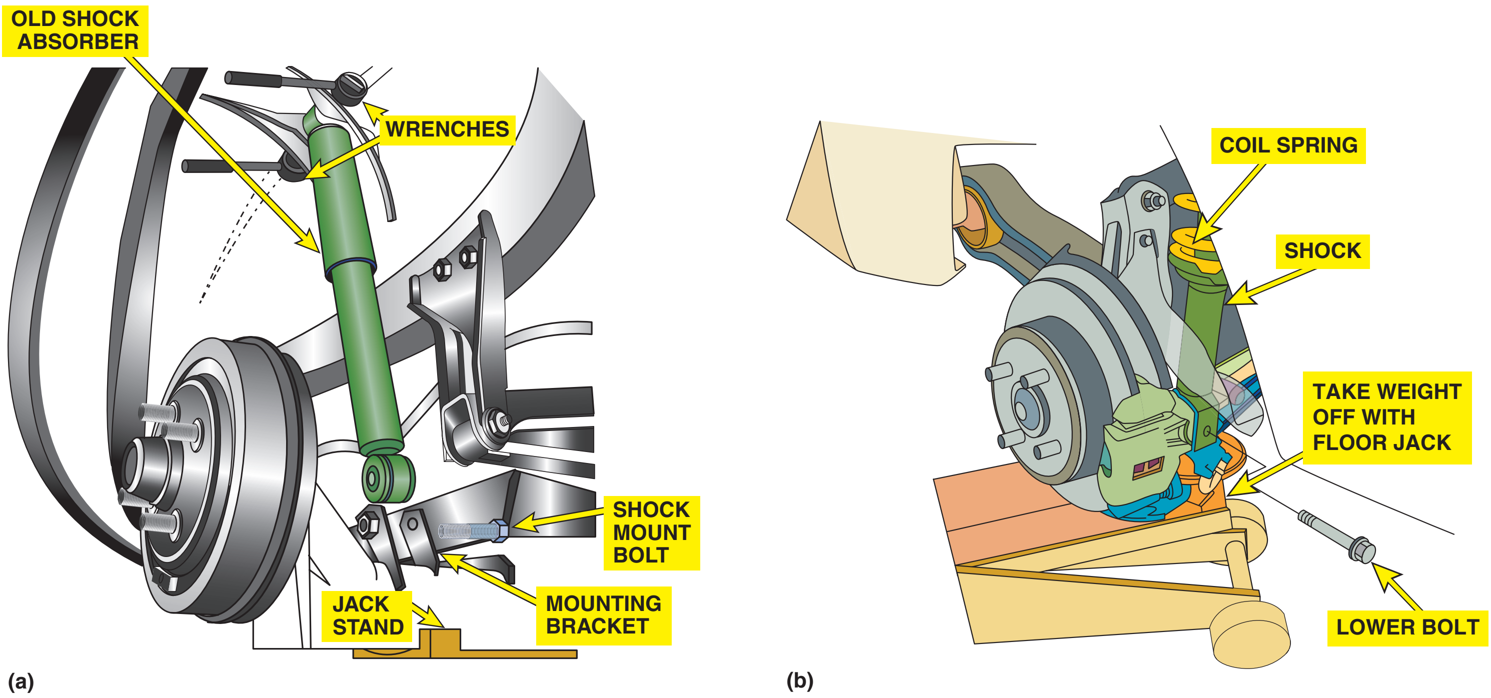

FIGURE 113–20 (a) The rear axle has to be supported before the rear shock absorber is removed. (b) Before removing a rear strut assembly, the rear axle has to be supported. Always follow the vehicle manufacturer's specified procedures.

CASE STUDY

The Harsh Riding Buick

The owner requested that all of the shock absorbers be replaced on a ten-year-old Buick. The rear was equipped with air shocks as part of the ride leveling system. During a test-drive after installing all four shocks, the service technician noticed that it seemed to ride much harsher than normal for a Buick. The technician asked the owner to ride along to verify that it was not usual to ride as harsh as it was. Puzzled as to why this occurred, the technician contacted the parts store, which then asked their supplier about the issue. It was discovered that the air shocks were not cycled before they were installed. Installing air shocks/struts requires cycling the shock/strut to spread lubricant inside the diaphragm to avoid binding. The installing technician should inflate the air diaphragm through the air fitting until the shock/strut fully extends. Then the shock can be kept fully extended to make it easier to install. After removing the rear shocks and inflating them as instructed, and reinstalling, the Buick rode normally.

Summary:

Complaint—The service technician was concerned that the Buick rode harsher than normal after new shock absorbers were installed.

Cause—The proper installation procedure was not followed prior to installing the air shock on the rear.

Correction—The air shocks were removed and cycled and then inflated before being reinstalled, which solved the harsh ride concern.

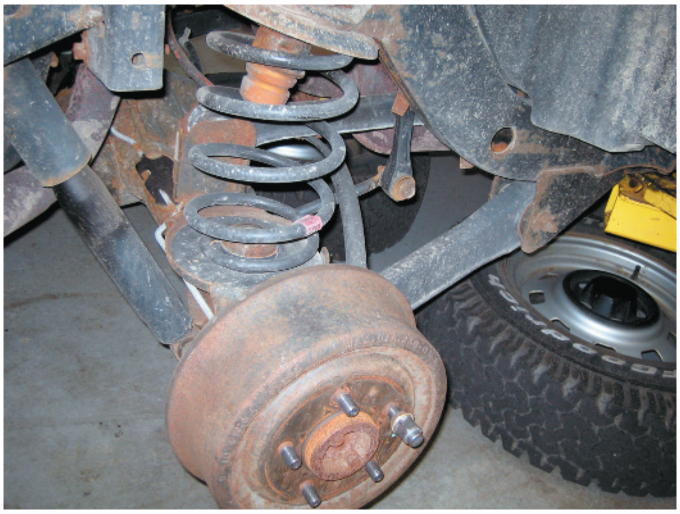

FIGURE 113–21 The shock absorber needs to be disconnected before removing the coil spring. Installation is the reverse of removal procedure.

REAR LEAF SPRINGS

REPLACEMENT Rear leaf springs often need replacement due to one of the following common causes:

1. Individual leaves of a leaf spring often crack, then break. When a leaf spring breaks, the load-carrying capacity of the vehicle decreases and it often sags on the side with the broken spring. Metal fatigue, corrosion, and overloading are three of the most common causes of leaf spring breakage. ● **SEE FIGURE 113–22.**

NOTE: When one rear spring on one side sags, the opposite front end of the vehicle tends to *rise.* For example, if the right-rear spring breaks or sags down, the left front of the vehicle tends to rise higher than the right front. This unequal vehicle height can make the vehicle difficult to handle, especially around corners or curves.

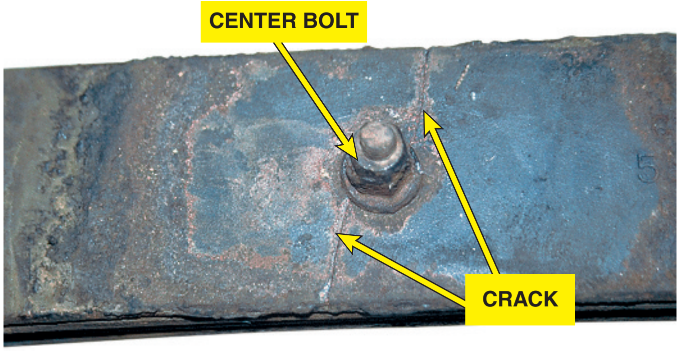

FIGURE 113–22 The center bolt is used to hold the leaves of the leaf spring together. However, the hole for the center bolt also weakens the leaf spring. The crack shown is what a technician discovered when the leaf spring was removed during the diagnosis of a sagging rear suspension.

CASE STUDY

Strange Leakage

The owner of a small business drove the company pickup truck into the shop to get it ready to load for the day's delivery. It was a very cold day in northern Ohio with the temperature well below freezing (32°F [0°C]). After about 15 minutes, the business owner noticed that "something" was leaking from underneath the rear of the truck. ● **SEE FIGURE 113–23**.

Not sure what it was, the owner called a local automotive repair shop and asked for help. The shop sent a technician to look at the truck. The service technician noticed that one of the rear shock absorbers had leaked all of the hydraulic fluid out of the bottom of the shock. ● **SEE FIGURE 113–24**.

Obviously, both rear shock absorbers would require replacement because shocks should always be replaced in pairs. The service technician recommended that all four (both front and both rear) shocks be replaced to restore proper handling. Knowing that the front shock absorbers were operating under the same conditions as the rear and were the same age, the truck owner approved the replacement of all four shock absorbers.

Summary:

Complaint—A liquid was found leaking from underneath a truck.
Cause—Hydraulic fluid had leaked from a rusty shock absorber.
Correction—Based on the owner's approval, all four shocks were replaced.

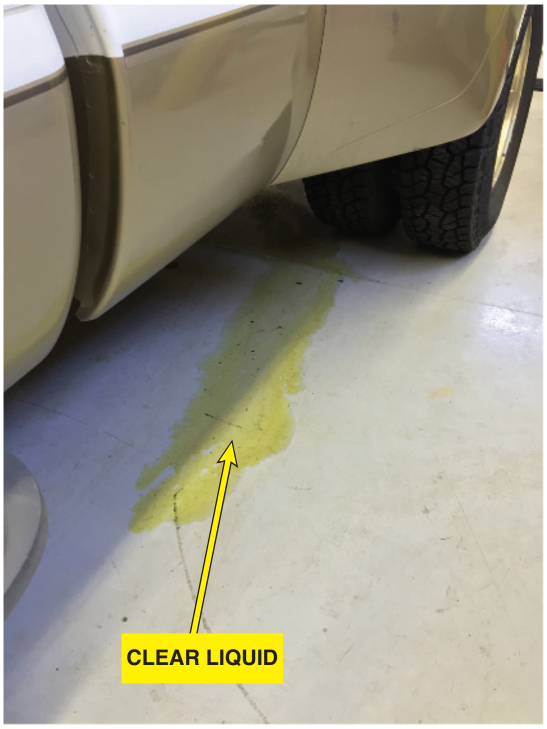

FIGURE 113–23 Whatever was leaking appeared to be a clear liquid but it did not smell like gasoline. What could it be from the rear of the truck?

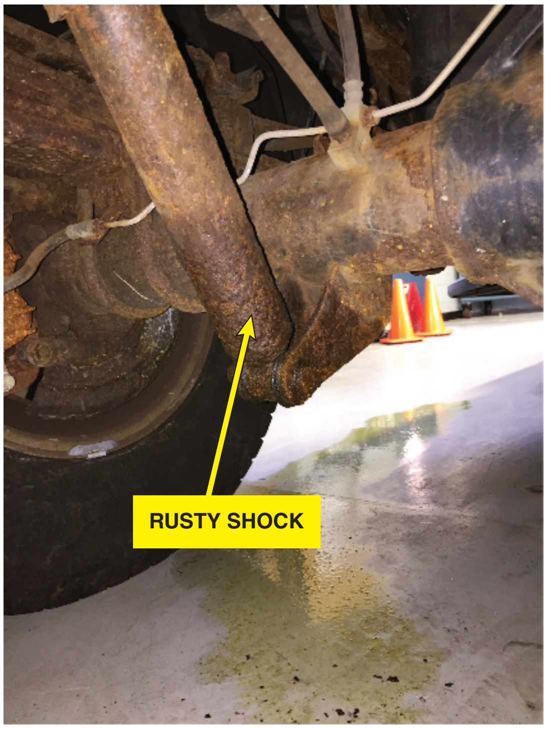

FIGURE 113–24 The source of the leak was discovered to be hydraulic shock fluid that had leaked from the bottom of the shock and not from around the shaft seal, which is the most likely location for shocks to leak. Apparently, rust had eaten through the housing of the shock.

2. If the center bolt breaks, the individual leaves can move and the rear axle is no longer held in the correct location. When one side of the rear axle is behind the other side, the vehicle will *dog track*. Dog tracking refers to the sideways angle of the vehicle while traveling straight. It is commonly caused by the rear axle steering the vehicle toward one side, while the driver controls the direction of the vehicle with the front wheels.

NOTE: Leaf springs should be replaced in pairs.

To replace leaf springs in the rear of a rear-wheel-drive vehicle, follow these steps:

1. Raise the vehicle safely on a hoist.
2. Support the rear axle with safety stands.
3. Remove the rear shackle bolts and forward mounting bolt or mounting bracket.
4. Remove the U-bolts.
5. Remove the spring, being careful of any nearby brake line.
6. Install the new spring, being careful to position the center bolt correctly into the hole on the axle pedestal.

THE NEED FOR ELECTRONIC SUSPENSIONS

Since the mid-1980s, many vehicle manufacturers have been introducing models with electronic suspension controls that provide a variable shock stiffness or spring rate. The main advantage of electronic controls is that the suspension can react to different conditions. The system provides a firm suspension feel for fast cornering and quick acceleration and braking, with a soft ride for cruising. ● **SEE FIGURE 114–1**.

ELECTRONIC SUSPENSION CONTROLS AND SENSORS

INPUTS AND OUTPUTS Sensors and switches provide **input** to the electronic control module (ECM), or system computer. The ECM, which may also be referred to as the **electronic control unit (ECU)**, is a small computer that receives input in the form of electrical signals from the sensors and switches and provides output electrical signals to the system actuators. ● **SEE FIGURE 114–2**. The electrical signal causes an **actuator** to perform some type of mechanical action.

HEIGHT SENSORS Sensors, which are the input devices that transmit signals to the ECM, monitor operating conditions and component functions. A **height sensor** senses the vertical relationship between the suspension component and the body. Its signal indicates to the ECM how high the frame or body is, or how compressed the suspension is. A number of sensor designs are used to determine ride height, including a photocell type of sensor. ● **SEE FIGURE 114–3**.

Four height sensors, one at each wheel, deliver an input signal to the ECM. All four sensors are similar and use a control link, lever, slotted disc, and four photo interrupters to transmit a signal. Each photo interrupter consists of a **light-emitting diode (LED)** and a **phototransistor**, which reacts to the LED.

Inside the sensor, the LEDs and phototransistors are positioned opposite each other on each side of the slotted disc. ● **SEE FIGURE 114–4**. When the system is activated, the ECM applies voltage to the LEDs, which causes them to illuminate. Light from an LED shining on the phototransistor causes the transistor to generate a voltage signal. Signals generated by the phototransistors are delivered to the ECM as an input that reflects ride height.

SENSOR LEVER

FIGURE 114–4 When suspension action moves the lever, it rotates the slotted disc and varies how much of the photo transistor is exposed to the LEDs, which vary the input signal.

As suspension movement rotates the disc, the slots or windows on the disc either allow light from the LEDs to shine on the phototransistors or prevent it. The windows are positioned in such a manner that, in combination with the four LEDs and transistors, the sensor is capable of generating 16 different levels of voltage. This variable voltage, which is transmitted to the ECM as an input signal, directly corresponds to 1 of 16 possible positions of the suspension. This input signal tells the ECM the position of the suspension in relation to the body. Whether the input voltage signal is increasing or decreasing allows the ECM to determine if the suspension is compressing or extending.

The ECM can also determine the relative position of the body to the suspension, or the attitude of the vehicle, from the four height sensors. Comparing front-wheel input signals to those of the rear wheels determines the amount of pitch caused by forces of acceleration or deceleration. A side-to-side comparison allows the ECM to determine the amount of body roll generated by cornering force.

GENERAL MOTORS ELECTRONIC SUSPENSION SENSORS

There are five different sensors found on electronic suspension systems, and GM vehicles can have between one and four of these sensors, depending on the system.

Depending on the vehicle, the *suspension position sensor* may be called by a different name. It can be called

- An automatic level control sensor
- An electronic suspension position sensor
- A position sensor
- An air suspension sensor

FIGURE 114–6 A three-wire suspension position sensor schematic.

The sensor provides the control module with information regarding the relative position and movement of suspension components. The common mounting location is between the vehicle body and the suspension control arm. ● **SEE FIGURE 114–5**.

The operation of the sensor is either an air suspension sensor two-wire type or a potentiometer three-wire type. The **air suspension** sensor is also known as a *linear Hall-effect* sensor. The air suspension sensor operation consists of a moveable iron core linked to the components. As the core moves, it varies the inductance of the internal sensor coil relative to suspension position.

The suspension control module energizes and de-energizes the coil approximately 20 times a second, thereby measuring sensor inductance as it relates to suspension position. The potentiometer three-wire sensor requires reference and ground voltage. Similar to the throttle position (TP) sensor, it produces a variable analog voltage signal. ● **SEE FIGURE 114–6**.

As the suspension moves up or down, an arm moves on the suspension position sensor through a ball-and-cup link. ● **SEE FIGURE 114–7**.

Suspension position sensor voltage changes relative to this movement. The sensor receives a 5 volt reference signal from the control module. The position sensor returns a voltage signal between 0 and 5 volts depending on suspension arm position.

NOTE: Some systems may require sensor learning or "reprogramming" after replacement. For instance, the sensor used on the Tahoe or Suburban needs to be programmed if replaced. Always check service information for the details and procedures to follow when replacing a sensor on the suspension.

STEERING WHEEL POSITION SENSOR Depending on the vehicle, the **steering wheel position sensor** may also be called a **handwheel position sensor**. The function of this sensor is to provide the control module with signals relating to steering wheel position, the speed, and direction of handwheel position.

The sensor is found on most **real-time dampening (RTD)** and road-sensing suspension (RSS) applications. The sensor is typically located at the base of the steering column. Always refer to service information for vehicle-specific information. ● **SEE FIGURES 114–8 AND 114–9**.

The handwheel sensor produces two digital signals, which are used by the **electronic brake control module (EBCM)**. These signals are produced as the steering wheel is rotated. The sensor can also produce more than two signals. As an example, the Cadillac Escalade handwheel sensor produces one analog and three digital signals.

The sensor uses a 5 volt signal reference. Analog signal voltage values increase or decrease, between 0 and 5 volts, as the steering wheel is moved left and right of center. The digital signal is also a standard power-to-ground circuit as shown in the schematic.

There are three possible digital signals:

- Phase A
- Phase B
- Index pulse

These signals provide the suspension control module with steering wheel speed and direction information. Digital signals are either high or low, 5 volts or 0 volts. ● **SEE FIGURE 114–10**.

A scan tool provides DTC (diagnostic trouble code) faults for this sensor. If there is an intermittent concern with a steering wheel position sensor, select snapshot and slowly turn the steering wheel lock to lock. After the snapshot is complete, plot

VEHICLE SPEED SENSOR The **vehicle speed (VS) sensor** is used by the EBCM to help control the suspension system. The vehicle speed sensor is a magnetic sensor and generates an analog signal whose frequency increases as the speed increases. The ride is made firmer at high speeds and during braking and acceleration and less firm at cruise speeds. ● **SEE FIGURE 114–11**.

PRESSURE SENSOR A pressure transducer (sensor) is typically mounted on the compressor assembly. This sensor is typically found on systems such as air suspension, real-time damping, and road-sensing suspension that use a compressor assembly. The main function of the pressure sensor is to provide feedback to the suspension control module about the operation of the compressor. The sensor assures both that a minimum air pressure is maintained in the system and that a maximum value is not exceeded. ● **SEE FIGURE 114–12**.

The operation of the pressure sensor requires a 5 volt reference, a ground, and a signal wire to provide feedback to the control module. The voltage output on the signal wire will vary from 0 to 5 volts based upon pressure in the system. A high voltage indicates high pressure and low voltage indicates a low pressure.

LATERAL ACCELEROMETER SENSOR The function of the **lateral accelerometer sensor** is to provide the suspension control module with feedback regarding vehicle cornering forces. This type of sensor is also called a G-sensor, with the letter "G" representing the force of gravity. For example, when a vehicle enters a turn, the sensor provides information as to how hard the vehicle is cornering. This information is processed by the suspension control module to provide appropriate damping on the inboard and outboard dampers during cornering events. The lateral accelerometer sensor is found on the more complex suspensions systems, such as RTD and RSS systems that incorporate the **vehicle stability enhancement system (VSES)**.

This sensor can be either a stand-alone unit or combined with the yaw rate sensor. Typically, the sensor is mounted in the passenger compartment under a front seat, center console, or package shelf.

The sensor produces a voltage signal of 0 to 5 volts as the vehicle maneuvers left or right through a curve. The signal is an input to the EBCM. If the lateral acceleration is zero, the sensor input is 2.5 volts. Check service information for specific codes that can be set.

If driving the vehicle and the voltage values increase or decrease during cornering events, this indicates proper operation. ● **SEE FIGURE 114–13**.

YAW RATE SENSOR The **yaw rate sensor** provides information to the suspension control module and the EBCM. This

TECH TIP

The Lateral Acceleration Sensor Needed to Control the Electronic Suspension

The lateral acceleration sensor is one part of the group of sensors that provides the information needed for the suspension to be able to react to driver commands and road conditions. Using just the steering wheel position sensor would not be enough information for the suspension controller to determine the cornering loads. ● **SEE FIGURE 114–14**.

information is used to determine how far the vehicle has deviated from the driver's intended direction. The yaw sensor is used on vehicles equipped with Electronic Stability Control (ESC).

This sensor can be either a stand-alone unit or combined with the lateral accelerometer sensor. Typically, the sensor is

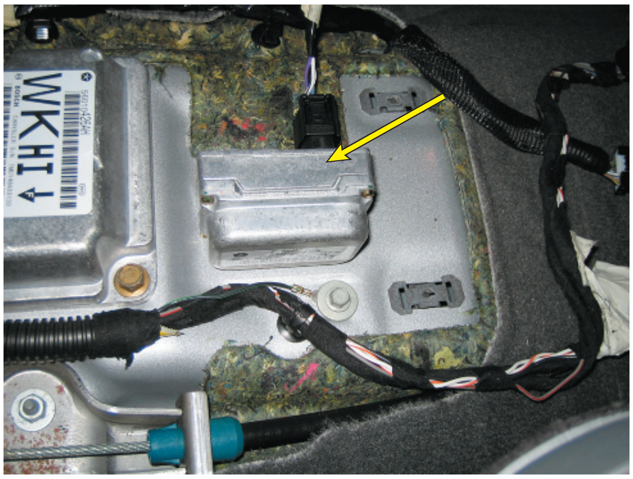

FIGURE 114–14 The lateral accelerometer sensor (G-sensor) is usually located under the center console. This sensor can be tested by unbolting the sensor, turning it on its side with the key on, engine off (KOEO), and looking at the scan tool data to verify that it reads 1 G.

mounted in the passenger compartment under the front seat, center console, or on the rear package shelf.

The sensor produces a voltage signal of 0 to 5 volts as the vehicle yaw rate changes. The voltage signal is an input to the EBCM. The yaw rate input to the EBCM indicates the number of degrees that the vehicle deviates from its intended direction.

For example, with a 0 degree yaw rate, the sensor output is 2.5 volts. During an emergency maneuver, the signal will vary above or below 2.5 volts. This sensor does set DTC codes. These codes can be found in service information. ● **SEE FIGURE 114–15.**

DRIVER SELECTOR SWITCH The **driver selector switch** is a two- or three-mode switch, usually located in the center console, and is an input to the suspension control module.

The switch that is used to select either touring (soft) or performance (firm) ride is found on the **selectable ride (SR)** and the computer command ride (CCR) systems. The mode select switch status is generally displayed on a scan tool. The three-position switch is used on the Corvette RTD system and allows the driver to select three modes of operation:

- Tour
- Sport
- Performance

ELECTRONIC SUSPENSION SYSTEM ACTUATORS

TERMINOLOGY Each actuator in an electronically controlled suspension system receives output signals from the ECM and responds to these signals, or commands, by performing a mechanical action. Actuators are usually inductive devices that operate using an electromagnetic field. A simple **electromagnet** consists of a soft iron core with a coil of wire, usually copper, wrapped around it. ● **SEE FIGURE 114–16.**

Electrical current traveling through the coiled wire creates a magnetic field around the core. All magnets are polarized; that is, they have a north, or positive, and a south, or negative, pole. When the opposite poles of two magnets are placed near each other—positive to negative—the magnets attract each other. Place the same poles together, positive to positive or negative to negative, and the magnets repel each other. ● **SEE FIGURE 114–17.** Magnets also attract and are attracted to certain types of metals, especially iron and steel.

When an electromagnet has more than one coil, the stronger primary coil can induce voltage into the weaker secondary coil.

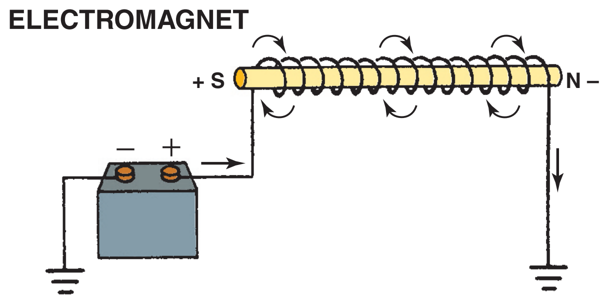

FIGURE 114–16 A magnetic field is created whenever an electrical current flows through a coil of wire wrapped around an iron core.

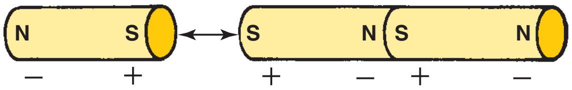

FIGURE 114–17 When magnets are near each other, like poles repel and opposite poles attract.

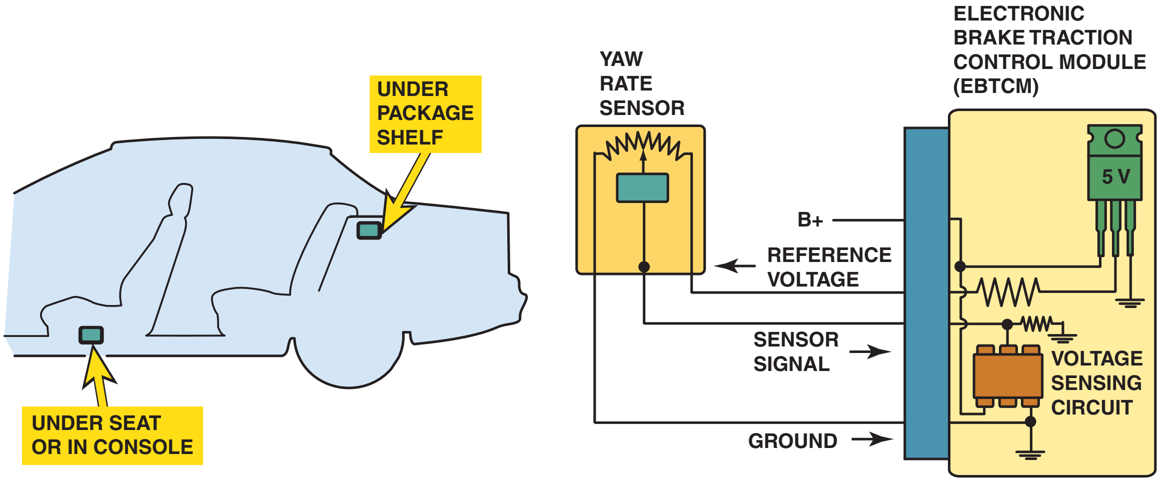

FIGURE 114–15 Yaw rate sensor showing the typical location and schematic.

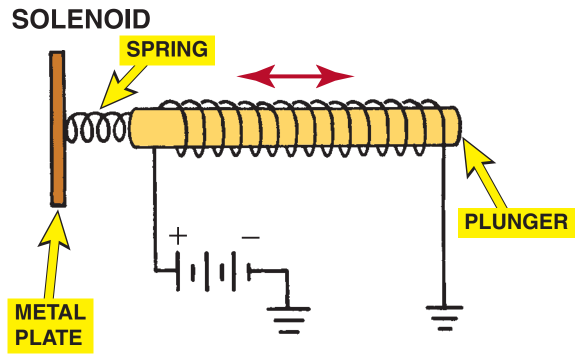

FIGURE 114–18 When electrical current magnetizes the plunger in a solenoid, the magnetic field moves the plunger against spring force. With no current, the spring pushes the plunger back to its original position.

This inductive transfer occurs even though there is no physical connection between the two coils.

SOLENOIDS In a **solenoid**, the core of the electromagnet also acts as a plunger to open and close a passage or to move a linkage. Solenoids are cylindrically shaped with a metal plate at one end and open at the other end to allow the plunger to move in and out. The electromagnetic coils are placed along the sides of the cylinder. A preload spring forces the plunger toward one end of the device when the solenoid is de-energized, or there is no current in the coil.

When the solenoid is energized, current passes through the coil and magnetizes the core. The magnetized core is attracted to the metal plate and the strength of the magnetic field overcomes spring force to pull the plunger inward. ● **SEE FIGURE 114–18**. When the electrical current switches off, the solenoid de-energizes and spring force returns the plunger to its rest position.

An airflow control valve is an example of a solenoid used in an electronically controlled suspension. ● **SEE FIGURE 114–19**. As the solenoid plunger extends and retracts, it opens and closes air passages between the system air-pressure tank and the air springs. The position of the plunger determines whether the springs receive more pressure or whether pressure bleeds out of them. Increasing the pressure in the air springs lifts the body higher, and decreasing the pressure by bleeding air from the springs lowers the body.

Solenoids are digital devices that are either on or off. However, the ECM can vary the amount a solenoid opens by pulsing the output signal to the coil. If the signal is rapidly switched on and off, spring and magnetic forces do not have enough time to react and effectively move the plunger between the signal changes. The amount of time the current is on compared to the amount of time it is off is called **pulse width**, and the control of a solenoid using this pulsing-on-and-off method is called **pulse-width modulation**.

ACTUATOR MOTORS If a current-carrying conductor is placed in a magnetic field, it tends to move from the stronger field area to the weaker field area. A motor uses this principle to convert electrical energy into mechanical movement. Electrical current is directed through the field coils on the motor frame to create a magnetic field within the frame. By applying an electrical current to the **armature**, which is inside the motor frame, the armature rotates from a strong field area to a weaker field area. Armature movement can in turn move another part, such as a gear, pulley, or shaft, attached to it.

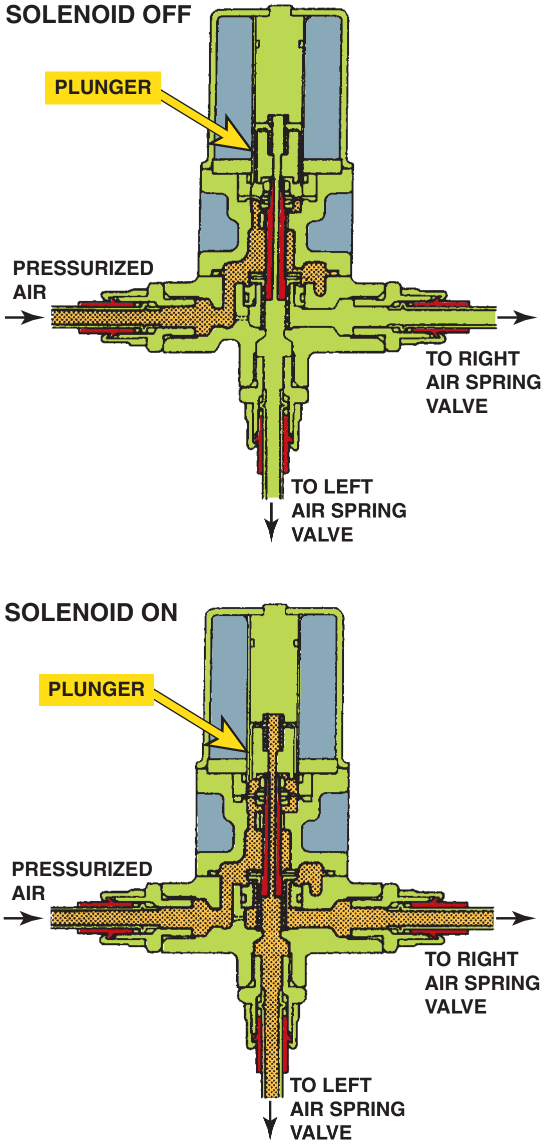

FIGURE 114–19 This air supply solenoid blocks pressurized air from the air spring valves when off. The plunger pulls upward to allow airflow to the air spring valves when the solenoid is energized.

Located at the top mount of the air spring variable shock assembly of each wheel, the suspension control actuator moves a control rod that regulates air pressure to the spring, which determines ride height. The actuator is an electromagnetic device consisting of four stator coils and a permanent magnet core. ● **SEE FIGURE 114–20**.

The ECM applies current to two stator coils at a time to create opposing magnetic fields around the core, which causes the core to rotate into a new position. Which coils are energized determines how far and in which direction the core rotates. ● **SEE FIGURE 114–21**. By switching current from one pair of coils to the other, the ECM moves the core into a new position, and a third position is available by reversing the polarity of the coils.

A gear at the base of the permanent magnet connects to a rod that operates the air valve to the air spring. The gear also drives another gear, which operates the control rod of the variable shock absorber. Therefore, the three positions of the suspension control actuator motor provide three shock absorber stiffness settings in addition to a variable air spring.

TYPES OF ELECTRONIC SUSPENSION

The types of electronic suspension systems used on General Motors vehicles, as examples, include

1. Selectable Ride
2. Automatic Level Control
3. Air Suspension
4. Computer Command Ride
5. Real-Time Dampening/Road-Sensing Suspension
6. Vehicle Stability Enhancement System
7. Magneto-Rheological Suspension (F55)

SELECTABLE RIDE The selectable ride (SR) system is the most basic of the electronic systems offered by General Motors. Selectable ride allows the driver to choose between two distinct damping levels:

- Firm
- Normal

SR is found on Chevrolet and GMC full-size pickup trucks. ● **SEE FIGURE 114–22**.

A switch is used to control four electronically controlled gas-charged dampers. The **mode select switch** activates the bi-state (two settings) dampers at all four corners of the vehicle, allowing the driver to select vehicle ride characteristics. The system is either energizing or de-energizing the bi-state dampers to provide a firm or normal ride.

AUTOMATIC LEVEL CONTROL The **automatic level control (ALC)** system automatically adjusts the rear height of the vehicle in response to changes in vehicle loading and unloading. ALC is found on many General Motors vehicles. ALC controls rear leveling by monitoring the rear suspension position sensor and energizing the compressor to raise the vehicle or energizing the exhaust valve to lower the vehicle. ALC has several variations across the different platforms. ● **SEE FIGURE 114–23**.

AIR SUSPENSION Air suspension (AS) is a system very similar to the ALC system. The purpose of the AS system is to

1. Keep the vehicle visually level.
2. Provide optimal headlight aiming.
3. Maintain optimal ride height.

FIGURE 114–23 ALC maintains the same ride height either loaded or unloaded by increasing or decreasing the air pressure in the rear air shocks.

The AS system includes the following components:

- An air suspension compressor assembly
- Rear air springs
- Air suspension sensors

The AS system is designed to maintain rear trim height within 3/16 inch (4 mm) in all loading conditions, and the leveling function will deactivate if the vehicle is overloaded.

The AS system also includes an accessory air inflator found in the rear cargo area. ● **SEE FIGURE 114–24**.

VARIABLE-RATE AIR SPRINGS In an air spring system with ordinary shock absorbers, the ECM uses the air springs to control trim height and is used on many Ford, Mercury, and Lincoln vehicles.

The three height sensors transmit a signal to the ECM that reflects trim height at each axle. ● **SEE FIGURE 114–25**. The ignition and brake light switches tell the ECM whether the ignition switch is on or off, and if the brake pedal is depressed. The dome light switch indicates whether any doors are open. The on/off switch disables the air spring system to avoid unexpected movement while towing or servicing the vehicle.

CAUTION: Failure to turn off the system will cause the air springs to be vented when the vehicle is hoisted. This will cause the vehicle to drop almost to the ground when the vehicle is lowered. This can cause damage to the air springs and/or to the vehicle. The shut-off switch is usually located in the trunk.

The ECM receives information from the height sensors indicating that the trim height is too high or too low, and it energizes the actuators to add or bleed air from the air springs. The system actuators can still operate for up to an hour after the ignition is switched off.

Any time the ignition is switched to the “run” position, the ECM raises the vehicle, if necessary, within the first 45 seconds. If trim height is too high and the vehicle must be lowered, the ECM delays doing so for 45 seconds after the ignition is switched on.

system, and a vent solenoid is used to relieve air pressure and deflate the springs. ● **SEE FIGURE 114–26**.

By energizing the compressor relay, the ECM directs current to turn on the compressor motor when trim height needs to be raised. The ECM command to lower the vehicle is an electrical signal that opens the vent solenoid to bleed air pressure out of the system. ● **SEE FIGURE 114–27**.

GENERAL MOTORS COMPUTER COMMAND RIDE The General Motors computer command ride (CCR) system controls ride firmness by automatically controlling an actuator in each of the four struts to increase ride firmness as speed increases.

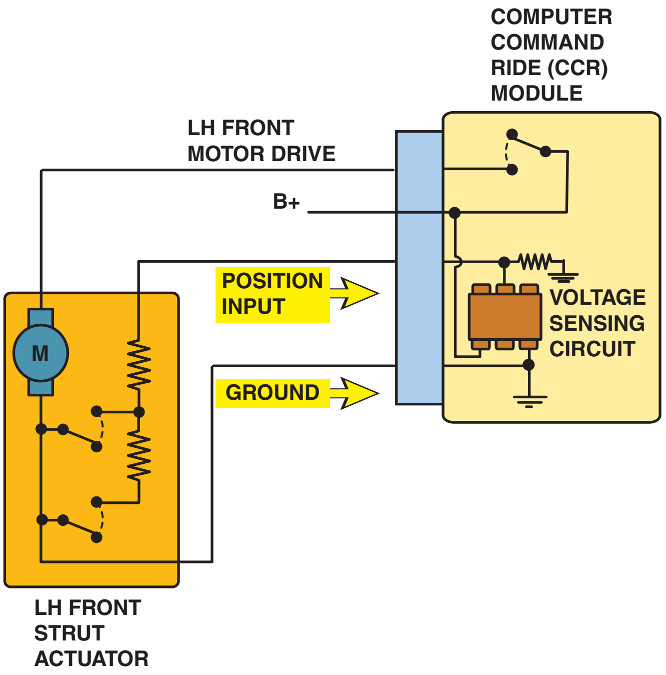

FIGURE 114–28 Schematic showing computer command ride system.

The three damping modes are

- Comfort
- Normal
- Sport

Damping mode selection is controlled by the CCR control module according to vehicle speed conditions, driver select switch position, and any error conditions that may exist.

In the perform ride mode, the system will place the damping level in the firm mode regardless of vehicle speed.

In the touring ride mode, the damping level depends on vehicle speed. ● **SEE FIGURE 114–28**.

REAL-TIME DAMPENING AND ROAD-SENSING SUSPENSION

Real-time dampening (RTD) independently controls a solenoid in each of the four shock absorbers in order to control the vehicle ride characteristics and is capable of making changes within milliseconds (0.001 second).

Road-sensing suspension (RSS), along with ALC, controls damping forces in the front struts and rear shock absorbers in response to various road and driving conditions.

Real-time damping suspension systems use inputs from the steering wheel position sensor, vehicle speed sensor (VSS), and a sensor cluster containing a lateral accelerometer and yaw rate sensor. These components may be indirect or direct inputs. ● **SEE FIGURE 114–29**.

RTD and RSS incorporate the following components:

- An electronic suspension control module
- Front and rear suspension position sensors
- Bi state dampers
- A ride select switch
- An air compressor is used on some models.

Check the RPO Code

Whenever working on the suspension system, check the **RPO (regular production option)** code for the type of suspension used. For example, the F55 RPO may be called by a different name depending on the make and model of vehicle. Also, service procedures will be different on the same vehicle depending on whether it is equipped with an F45 or an F55 system. The General Motors vehicle RPO codes are on a sticker on the spare tire cover in the trunk or in the glove compartment.

FIGURE 114–31 Bi-state dampers (shocks) use a solenoid to control fluid flow in the unit to control compression and rebound actions.

BI-STATE AND TRI-STATE DAMPERS The bi-state damper is also known as a **solenoid controlled damper**. Bi-state dampers are found on the RTD, RSS, and SR systems. Each of the suspension dampers used in these systems have an integral solenoid. The solenoid valve provides various amounts of damping by directing hydraulic damping fluid in the suspension shock absorber or strut.

The General Motors version of ESC is called the vehicle stability enhancement system (VSES) and includes an additional level of vehicle control to the EBCM. VSES is also known as **Stabilitrak**.

The purpose of the vehicle stability enhancement system along with the antilock brake system (ABS) is to provide vehicle stability enhancement during oversteer or understeer conditions.

The pulse-width modulation (PWM) voltage signal from the suspension control module controls the amount of current flow through each of the damper solenoids. With a low PWM signal de-energized, more hydraulic damping fluid is allowed to bypass the main suspension damper passage, resulting in a softer damping mode.

As the PWM signal increases, or is energized, the damping mode becomes more firm. ● **SEE FIGURE 114–32**.

NOTE: If the suspension module does not control the shock absorber solenoid, a full soft damping mode results. In some system malfunctions, the module may command one or all of the damper solenoids to a full soft damping.

The main difference between a tri-state damper and a bi-state damper is that the tri-state damper uses an electrical actuator, whereas the bi-state damper is solenoid controlled.

The three damping modes include

- Comfort
- Normal
- Sport

A tri-state damper has an integral electrical strut actuator that rotates a selector valve to change the flow of hydraulic damping fluid. ● **SEE FIGURE 114–33**.

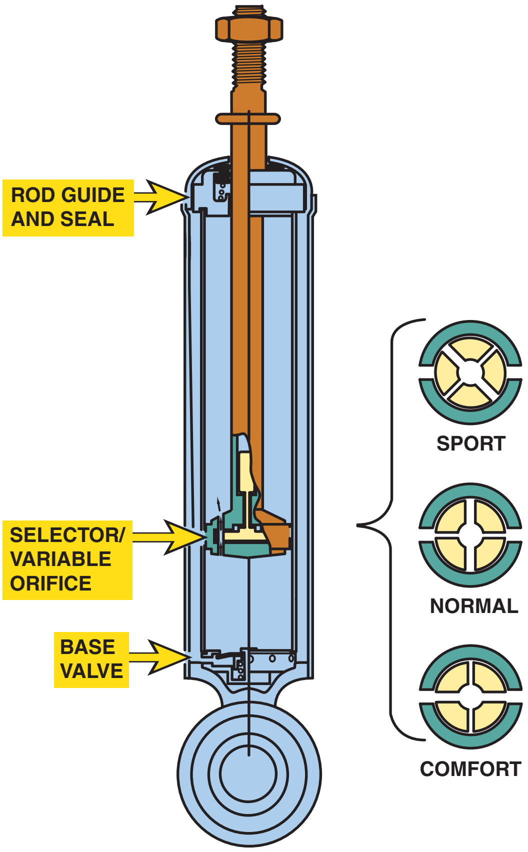

FIGURE 114–33 The three dampening modes of a CCR shock absorber.

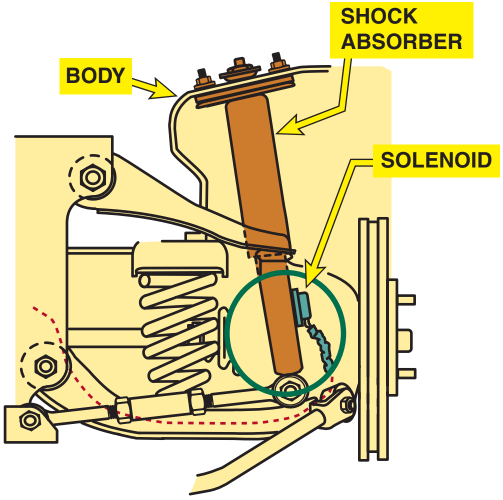

FIGURE 114–34 Integral shock solenoid.

The CCR module controls the operation of the strut actuators to provide the three damping modes.

The strut position input provides feedback to the CCR module. The strut position input is compared to the commanded actuator position to monitor system operation. ● **SEE FIGURE 114–34**.

AUTOMATIC LEVEL CONTROL (ALC)

PARTS AND OPERATION Vehicles that have an air inflator system as part of the ALC system also have an air inflator switch. The air inflator switch is an input to the ALC and AS system.

FREQUENTLY ASKED QUESTION

What Are Self-Leveling Shocks?

A German company, ZF Sachs, supplies a self-leveling shock absorber to several vehicle manufacturers, such as Chrysler for use on the rear of minivans, plus BMW, Saab, and Volvo. The self-leveling shocks are entirely self-contained and do not require the use of height sensors or an external air pump. ● **SEE FIGURE 114–35**.

The shock looks like a conventional shock absorber but contains the following components:

- Two reservoirs in the outer tube
- An oil reservoir (low-pressure reservoir)
- A high-pressure chamber

Inside the piston rod is the pump chamber containing an inlet and an outlet valve. When a load is placed in the rear of the vehicle, it compresses the suspension and the shock absorber. When the vehicle starts to move, the internal pump is activated by the movement of the body. Extension of the piston rod causes oil to be drawn through the inlet valve into the pump. When the shock compresses, the oil is forced through the outlet valve into the high-pressure chamber. The pressure in the oil reserve decreases as the pressure in the high-pressure chamber increases. The increasing pressure is applied to the piston rod, which raises the height of the vehicle.

When the vehicle's normal height is reached, no oil is drawn into the chamber. Because the shock is mechanical, the vehicle needs to be moving before the pump starts to work. It requires about 2 miles of driving for the shock to reach the normal ride height. The vehicle also needs to be driven about 2 miles after a load has been removed from the vehicle for it to return to normal ride height.

The inflator switch is used to control the air inflator system operation and provides a signal to the ALC or AS module to initiate compressor activation.

With the ignition on, the driver can turn the system to ON. The switch will command the compressor to run for up to 10 minutes, allowing time to inflate a tire or other items requiring air.

NOTE: There are no DTCs associated with compressor assembly.

INFLATOR OR COMPRESSOR RELAY The suspension control module energizes the relay to activate the compressor motor. This adjusts the rear trim height as needed. The suspension control module controls the compressor relay for normal operation or for the accessory air inflator.

To avoid compressor overheating, the timer within the suspension control module limits the compressor run time to 10 minutes. ● **SEE FIGURE 114–36**.

On RTD or RSS systems with a compressor, the scan tool may display DTCs associated with compressor relay operation. On some vehicle applications, the scan tool will display data relating to relay operation and can be used to command the relay to verify proper operation.

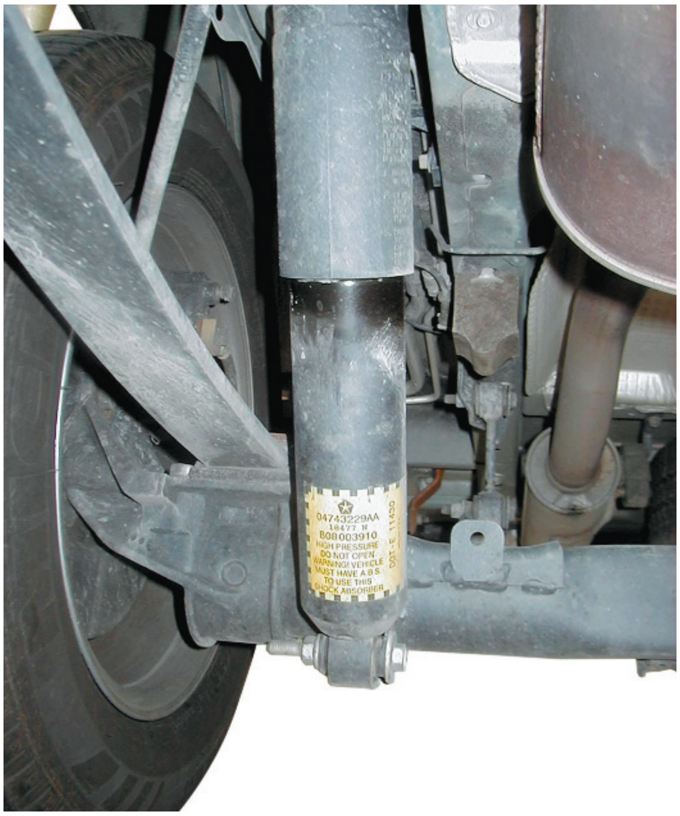

FIGURE 114–35 A typical ZF Sachs self-leveling shock, as used on the rear of a Chrysler minivan.

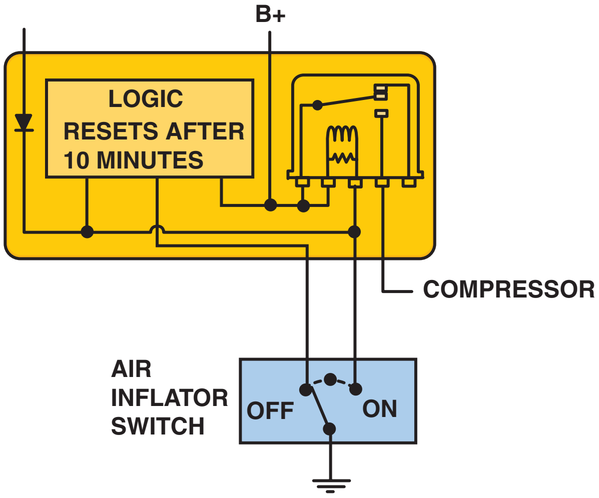

FIGURE 114–36 Schematic of the ALC system.

COMPRESSOR The compressor is a positive-displacement air pump and can generate up to 150 pounds of pressure per square inch (PSI). The compressor is found on the ALC, AS, RTD, and RSS systems. A 12 volt permanent magnet motor drives the compressor. The compressor supplies compressed air to the rear air shock absorbers or struts to raise the vehicle. ● **SEE FIGURE 114–37**.

AIR DRYER Within the compressor is an air dryer. The air dryer is responsible for removing moisture from the compressor system. Improper air dryer operation can cause a premature failure

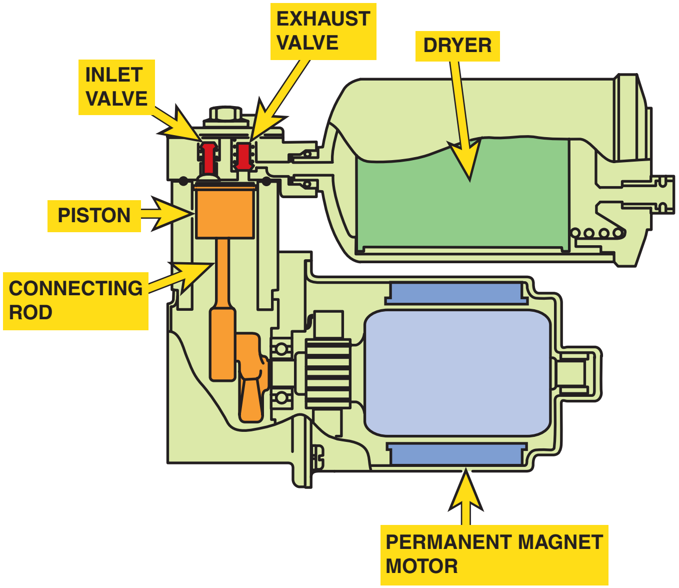

FIGURE 114–37 Air compressor assembly can be located at various locations depending on the vehicle.

in the system if an air line restriction occurs due to excessive moisture buildup. A dryer on the output side of the compressor contains silica gel **desiccant**, which removes moisture from the discharge air before it travels through the nylon air hoses to the air chamber of the rear shocks.

EXHAUST SOLENOID The exhaust solenoid, which is located on the compressor, relieves pressure in the system. The ground-side switched exhaust solenoid has three main functions:

1. It releases compressed air from the shock absorbers or air springs to lower the vehicle body.
2. It relieves compressor head pressure. By exhausting air, it protects compressor start-up from high head pressure, which can possibly cause fuse failure.
3. The solenoid acts as a pressure relief valve, which limits overall system pressure.

The special functions on many scan tools can be used to command the solenoid and to verify its operation. ● **SEE FIGURE 114–38**.

TROUBLESHOOTING REAR ELECTRONIC LEVELING SYSTEMS

The first step with any troubleshooting procedure is to check for normal operation. Some leveling systems require that the ignition key be on (run), while other systems operate all the time. Begin troubleshooting by placing approximately 300 pounds (135 kg) on the rear of the vehicle. If the compressor does not operate, check to see if the sensor is connected to a rear suspension member and that the electrical connections are not corroded.

Also check the condition of the compressor ground wire. It must be tight and free of rust and corrosion where it attaches to the vehicle body. If the compressor still does not run, check to see if 12 volts are available at the power lead to the compressor. If necessary, use a fused jumper wire directly from the positive (+) of the battery to the power lead of the compressor. If the compressor does not operate, it must be replaced.

If the ride height compressor runs excessively, check the air compressor, the air lines, and the air shocks (or struts) with soapy water for air leaks. Most air shocks or air struts are not repairable and must be replaced. Most electronic leveling systems provide some adjustments of the rear ride height by adjusting the linkage between the height sensor and the rear suspension. ● **SEE FIGURE 114–39**.

MAGNETO-RHEOLOGICAL (MR) SUSPENSION

TERMINOLOGY MR fluid shocks use a working fluid inside the shock that can change viscosity rapidly depending on electric current sent to an electromagnetic coil in each device. The fluid is called **magneto-rheological (MR)** and is used in monotube-type shock absorbers. This type of shock and suspension system is called the magneto-rheological real-time damping (MRRTD) or chassis continuously variable real-time dampening magneto-rheological suspension (CCVRTMR).

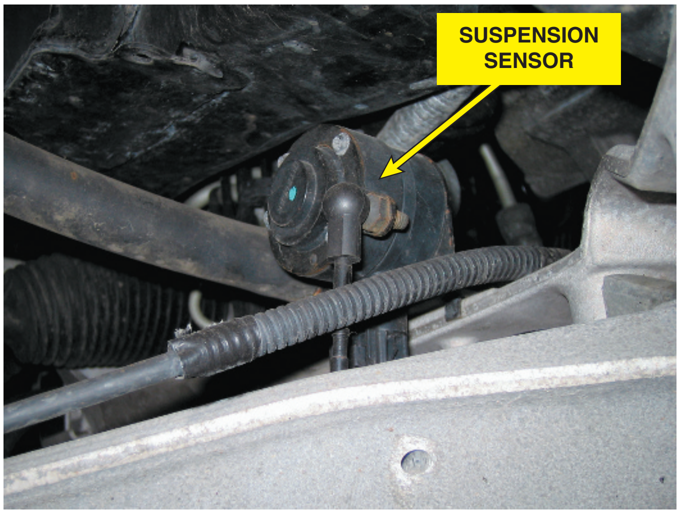

FIGURE 114–40 Vehicles that use magneto-rheological shock absorbers have a sensor located near each wheel, as shown on this C6 Corvette.

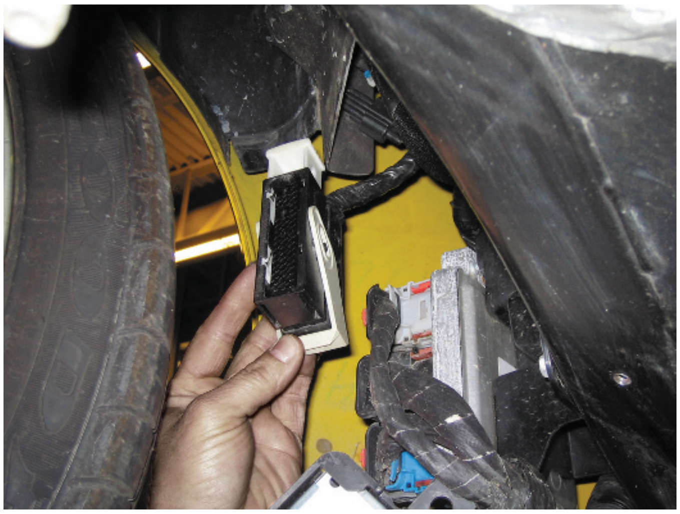

FIGURE 114–41 The controller for the magneto-rheological suspension system on a C6 Corvette is located behind the right front wheel.

Under normal operating conditions, the fluid flows easily through orifices in the shock and provides little dampening. When a large or high-frequency bump is detected, a small electrical current is sent from the chassis controller to an electromagnetic coil in each shock and the iron particles in the fluid respond within 3 milliseconds (ms), aligning themselves in fiber like strands. ● **SEE FIGURES 114–40 AND 114–41**.

This causes the MR fluid to become thick like peanut butter and increases the firmness of the shock. This type of shock absorber is used to control squat during acceleration and brake dive as well as to reduce body roll during cornering by the chassis controller. ● **SEE FIGURE 114–42**.

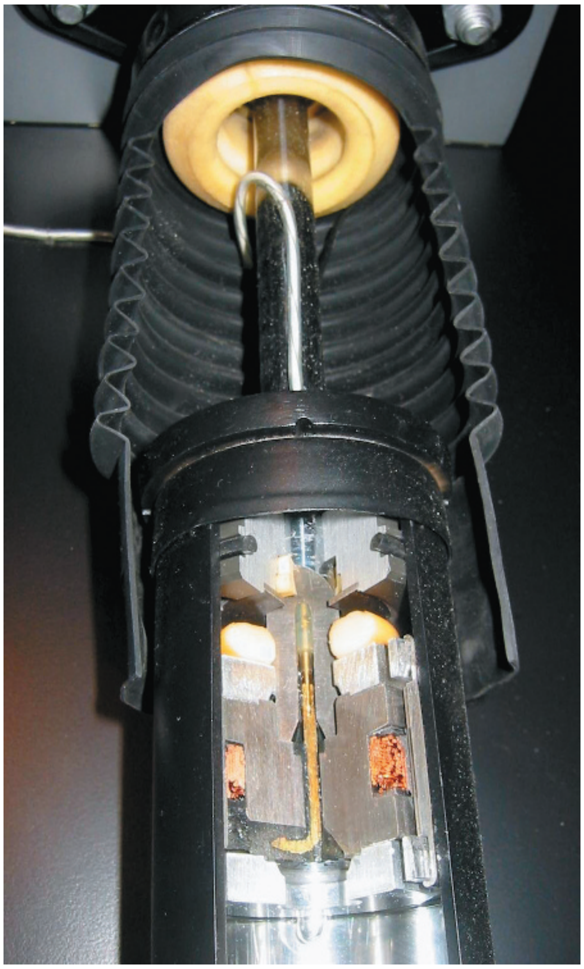

FIGURE 114–42 A cutaway of a magneto-rheological shock absorber as displayed at the Corvette Museum in Bowling Green, Kentucky.

FREQUENTLY ASKED QUESTION

Can Computer-Controlled Shock Absorbers and Struts Be Replaced with Conventional Units?

Maybe. If the vehicle was manufactured with or without electronic or variable shock absorbers, it may be possible to replace the originals with the standard replacement units. The electrical connector must be disconnected, and this may cause the control system to store a diagnostic trouble code (DTC) and/or turn on a suspension fault warning light on the dash. Some service technicians have used a resistor equal in resistance value of the solenoid or motor across the terminals of the wiring connector to keep the controller from setting a DTC. All repairs to a suspension system should be done to restore the vehicle to like-new condition, so care should be exercised if replacing electronic shocks with nonelectronic versions.

Chapter 115

STEERING COLUMNS AND GEARS

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Describe the purpose and function of a steering wheel.
- Explain how to remove a steering wheel.
- Discuss steering columns and intermediate shafts.
- Explain the purpose and function of conventional steering gears.
- Explain how a recirculating ball steering gear works.
- Describe how a rack-and-pinion steering gear works.

KEY TERMS:

Collapsible column 1422 • Flexible coupling 1421 • Inflator module 1418 • Kickback 1429 • Lock plate 1423 • Pitman arm 1425 • Pitman shaft 1425 • Rack-and-pinion 1426 • Rack support 1427 • Sector gear 1425 • Sector shaft 1425 • Steering shaft 1420 • Stub shaft 1423 • Tilt steering column 1422 • Universal joint 1421 • Variable ratio 1425 • Worm gear 1425

STEERING WHEELS

PURPOSE AND FUNCTION The steering wheel, which consists of a rigid rim and a number of spokes connecting the rim to a center hub, attaches to the top of the steering shaft at its center. Most steering wheel hubs have internal splines that fit over external splines on the steering shaft. A bolt or nut at the center of the hub secures the wheel to the shaft. The steering wheel may also contain controls for the cruise control and audio controls, as well as the driver's airbag.

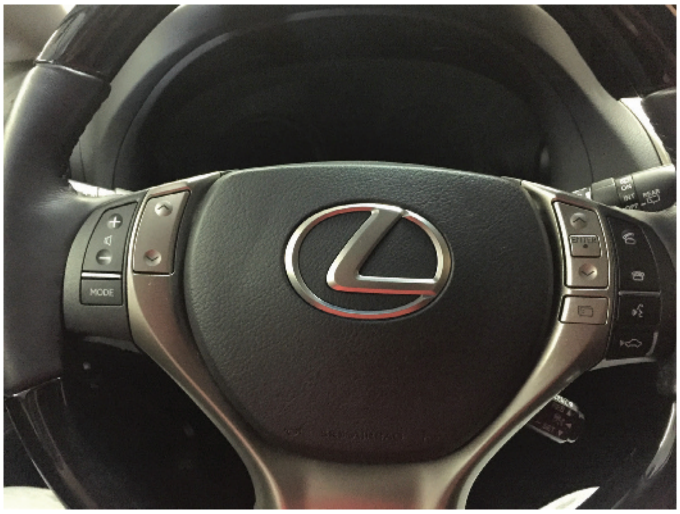

FIGURE 115–1 A steering wheel assembly includes a driver's side air bag module plus many also include steering wheel controls.

AIRBAGS An airbag is a device made of nylon cloth that is covered with neoprene. The airbag is folded and stored in the front center of the steering wheel. In a front-end collision, the airbag inflates in a fraction of a second to provide a cushion between the driver and the steering wheel and dashboard. ● **SEE FIGURES 115–1 AND 115–2**. The part of the steering wheel where the airbag is stored is called the **inflator module**. The module also contains an igniter, a canister of flammable gas, and a number of sodium azide pellets. The sodium azide pellets burn quickly and rapidly release nitrogen gas while they burn. The nitrogen gas fills the airbag. As it inflates, the airbag tears open the module cover and spreads out across the steering wheel, windshield, and dashboard. The entire process, from sensor reaction to full airbag deployment, takes 30 to 65 milliseconds. Within a second of inflating, the bag deflates partially as the nitrogen gas escapes through exhaust vents in the side of the airbag. Once deployed, an airbag cannot be reused.

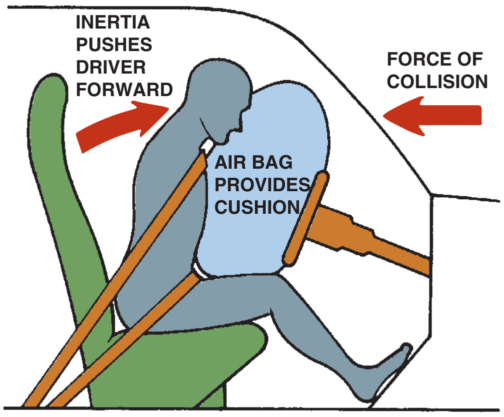

FIGURE 115–2 The airbag inflates at the same time the driver moves toward the steering wheel during a front-end collision and supplements the protection of the safety belt.

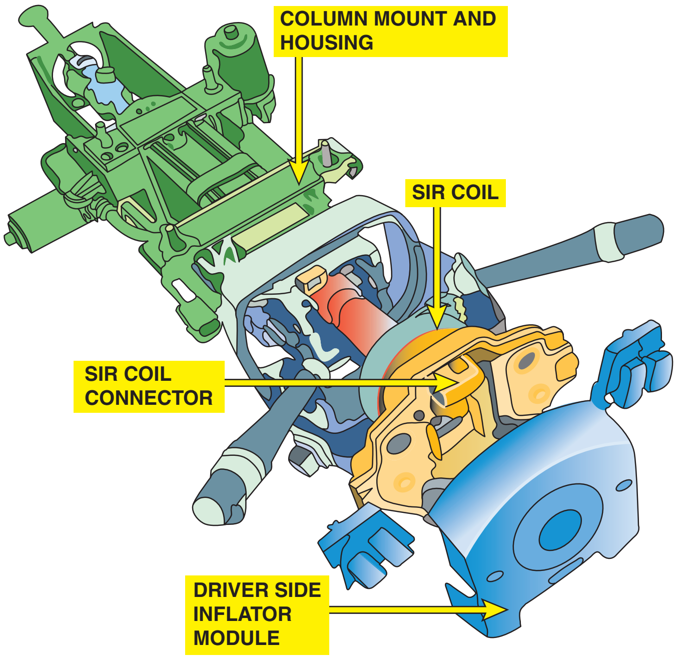

FIGURE 115–3 The airbag module attaches to the steering wheel and is removed as an assembly to service the steering wheel and column.

The module fits in front of the nut that secures the steering wheel to the steering shaft. Bolts at the back of the steering wheel fasten the airbag module to the steering wheel. Electrical current is provided to the airbag through the spiral cable, which is also known as a clockspring or coil. The spiral cable connects to the airbag module with two wire leads. The spiral cable is a coiled metal strip that allows steering wheel rotation while maintaining electrical continuity. ● **SEE FIGURE 115–3.**

CAUTION: Whenever working on the steering column, consult service information for the recommended airbag disabling procedure.

STEERING WHEEL REMOVAL

If the steering wheel must be removed, first disconnect the airbag wire connector at the base of the steering column. This reduces the chance of personal injury and prevents accidental airbag deployment.

TECH TIP

Locking Pliers to the Rescue

Many vehicles use a jam nut on the tie rod end. This jam nut must be loosened to adjust the toe. Because the end of the tie rod is attached to a tie rod end that is movable, loosening the nut is often difficult. Every time force is applied to the nut, the tie rod end socket moves and prevents the full force of the wrench from being applied to the nut. To prevent this movement, simply attach locking pliers (Vise Grips®) to hold the tie rod. Wedge the pliers against the control arm to prevent any movement of the tie rod. By preventing the tie rod from moving, full force can be put on a wrench to loosen the jam nut without doing any harm to the tie rod end.

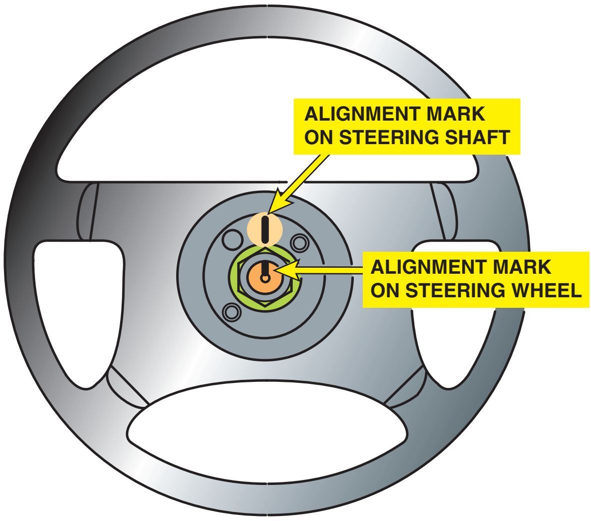
CAUTION: Always follow the manufacturer's recommended procedures whenever working on or around the steering column.

Remove the center section of the steering column by removing the retaining screws, including the inflator module on vehicles equipped with an airbag.

After removal of the airbag inflator module, remove the steering wheel retaining nut. Note the locating marks on the steering wheel and steering shaft. ● **SEE FIGURE 115–4.** These marks indicate the proper position of the steering wheel for centerline steering. This means that the steering wheel spoke angle is straight and in line with the centerline position of the steering gear or rack-and-pinion steering unit.

Most steering wheels are attached to the steering shaft with a spline and a taper. After removing the steering wheel nut, use a steering wheel puller to remove the steering wheel from the steering shaft. ● **SEE FIGURE 115–5.**

To reinstall the steering wheel, align the steering wheel in the desired straight-ahead position and slip it down over the splines. Install and tighten the retaining nut to specifications.



ALIGNMENT MARK ON STEERING SHAFT
ALIGNMENT MARK ON STEERING WHEEL

FIGURE 115–4 Most vehicles have alignment marks made at the factory on the steering shaft and steering wheel to help the service technician keep the steering wheel in the center position.

STEERING COLUMNS

PURPOSE AND FUNCTION The steering shaft transmits rotary motion from the steering wheel to the steering gear, while the column jacket that encases it attaches to the vehicle body and offers a stationary mounting point for a number of switches and mechanisms. ● **SEE FIGURE 115–6**.

STEERING SHAFT The **steering shaft** extends from the steering wheel to the steering gear. A bolt or nut secures the shaft to the steering wheel, and a flexible coupling joins it to the steering gear input shaft. The coupling can be a simple rubber or fabric insert, a universal joint (U-joint), or a pot joint.

FIGURE 115–8 A typical intermediate steering shaft assembly showing a U-joint and related components.

In addition to allowing a directional change of the shaft, a pot joint permits a limited amount of plunging motion. ● **SEE FIGURE 115–7**.

UNIVERSAL JOINT A **universal joint**, or U-joint, consists of two yokes with a steel crosspiece joining them together. ● **SEE FIGURE 115–8**. Universal joints allow changes in the angle between two rotating shafts. In a steering shaft, U-joints allow rotary motion transfer between the steering wheel and the steering gear even though the steering shaft meets the steering gear input shaft at an angle. On some models the steering shaft itself is assembled in sections that are connected by U-joints. This permits the steering shaft to bend around obstacles between the steering wheel and the steering gear.

FLEXIBLE COUPLING A **flexible coupling** is a simple device made of rubber, or rubber reinforced with fabric, that is placed between two shafts to allow for a change in angle between them. ● **SEE FIGURE 115–9**. The rubber in a steering shaft flexible coupling absorbs vibrations and helps keep the steering wheel from shaking. A fail-safe connection between the steering shaft and the steering gear input shaft keeps the two shafts linked should the rubber coupling wear out or break. This allows the driver to maintain steering control, although the steering feels loose when this happens.

FIGURE 115–9 A flexible coupling is used to isolate road noise and vibration from the steering shaft.

COLUMN COVER To keep the wiring from the jacket-mounted switches out of sight, the part of the steering column that extends into the passenger compartment is shrouded by the column cover. ● **SEE FIGURE 115–10**. The column cover is usually at least two separate pieces, top and bottom. A knee

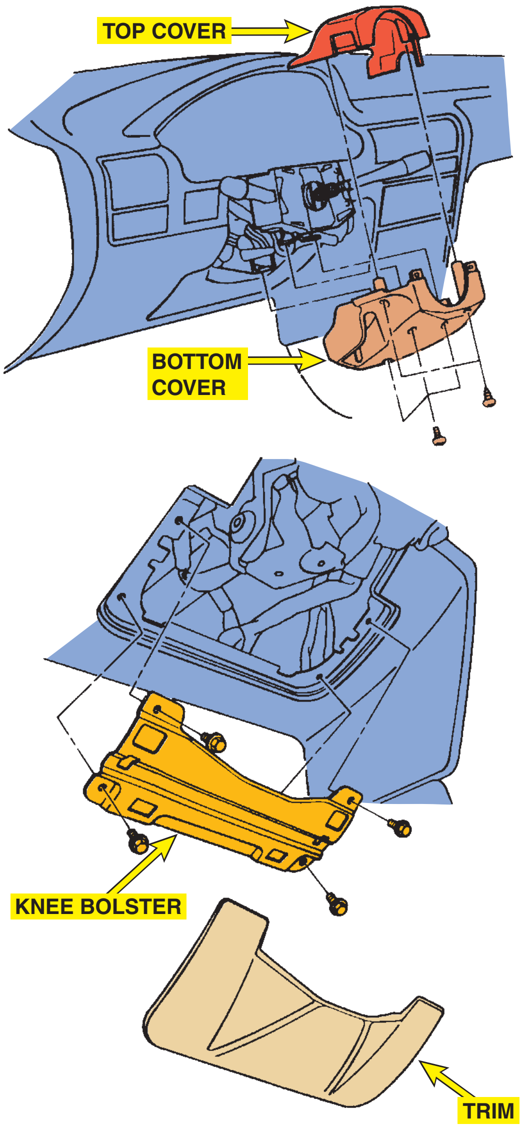

FIGURE 115–10 Steering column covers are often part of the interior trim.

bolster that mounts under the steering column is a safety feature designed to keep the driver from sliding forward during a collision. Knee bolsters are part of the passive restraint system required to meet U.S. federal safety standards on certain vehicles.

COLLAPSIBLE COLUMN Federal law requires that all vehicles sold in the United States have steering columns and shafts that collapse, **collapsible columns**, during a head-on collision to absorb some of the energy of the crash and lessen the danger of injury to the driver. ● **SEE FIGURE 115–11**. One early method used a section of the steering column constructed out of mesh, which would collapse easily during a crash. Another method is to use a two-piece column. One section of the column has a smaller diameter so that it fits inside the other and rides on a roller bearing. During a collision, the smaller section slides down into the larger one to collapse like a telescope.

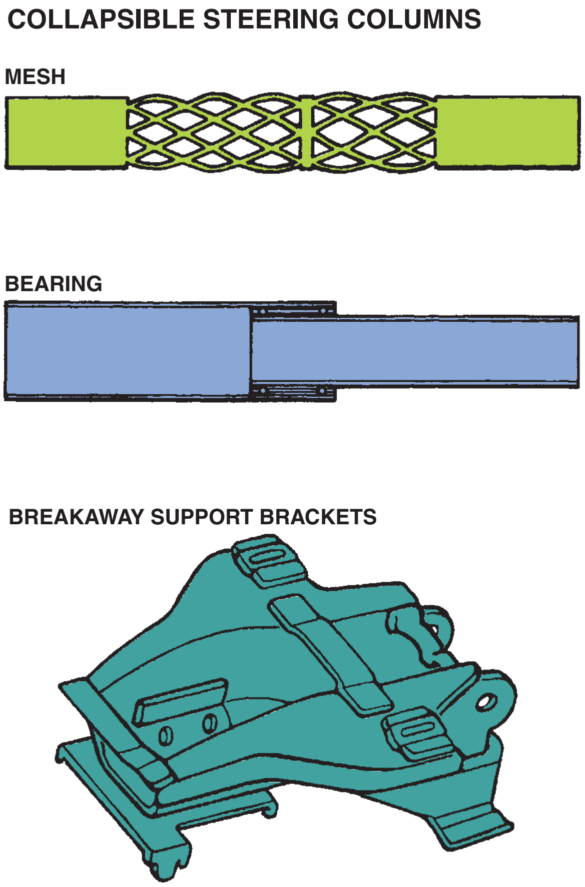

FIGURE 115–11 Collapsible steering columns include a mesh design that crushes easily, a bearing design that allows one section of the column to slide into the other, and a breakaway device that separates the steering column from the body of the vehicle in the event of a front-end collision.

TILT MECHANISMS Many steering columns have tilt mechanisms, which allow the driver to adjust the angle of the steering wheel relative to the steering column. In a typical **tilt steering column**, the steering shaft has a short section at the top joined to the rest of the steering shaft either by a U-joint or gears. Most tilt mechanisms are some sort of ratchet device that enables the driver to lift the steering wheel and the top section of the shaft and place them in the desired position. ● **SEE FIGURE 115–12**. Usually, spring tension locks the steering wheel in place on the ratchet, and a release lever compresses the spring to allow tilt adjustment.

TELESCOPING STEERING COLUMNS Some steering columns are designed to telescope, which means that the top of the steering shaft and jacket can be pulled out toward the driver or pushed in toward the dashboard, and then locked into the new position.

TECH TIP

Do Not Pound on the Steering Column

Always use a steering wheel puller and/or the special tools recommended by the vehicle manufacturer when servicing the steering column. If a hammer is used on the steering shaft in an attempt to remove a steering wheel, the shaft could collapse, requiring the replacement of the entire steering column assembly.

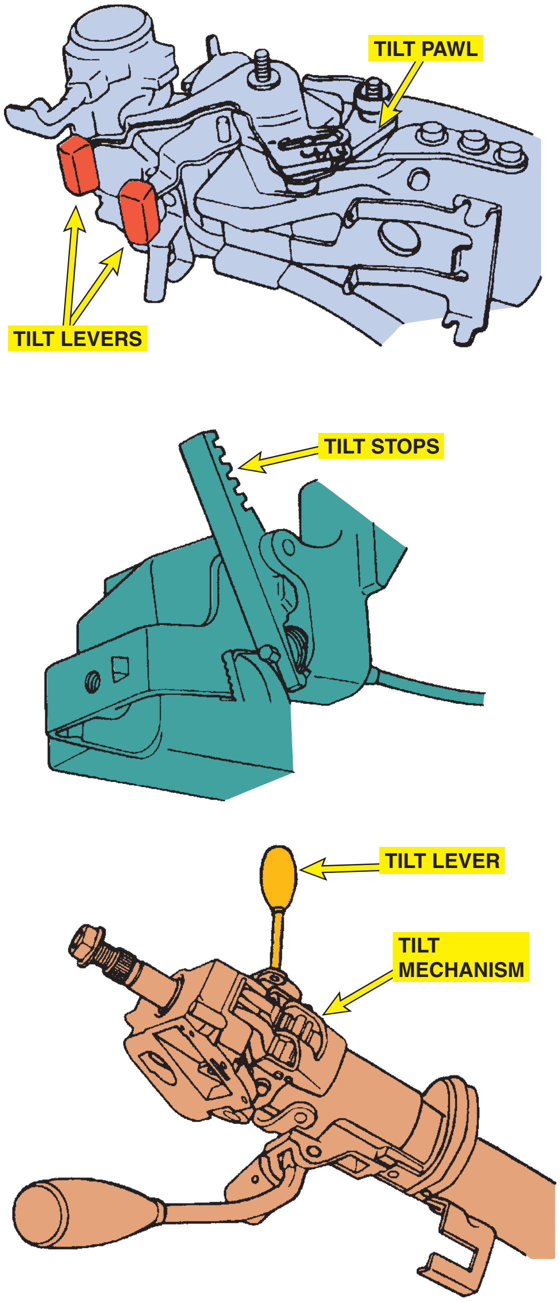

FIGURE 115–12 Tilt mechanisms vary by design and vehicle manufacturer, although most use a ratchet to position the top portion of the steering column.

STEERING COLUMN CONSTRUCTION The steering shaft is at the center of the steering column. ● **SEE FIGURES 115–13 AND 115–14**. The top end of the steering shaft splines to the center of the steering wheel, and a large nut fastens the steering wheel to the shaft. The lock housing, which contains the ignition lock cylinder, encases the top part of the steering shaft. The steering column jacket covers the shaft under the ignition lock housing, and the gear selector lever housing fits over a portion of the column jacket.

A U-joint connects the lower end of the steering shaft to a small intermediate shaft, often called a **stub shaft**. Because this steering column includes a gear selector lever, the lower end of the column also incorporates an attachment point that connects the shift tube to the gear shift rod. The intermediate shaft extends through a hole in the floor where it is coupled to the steering gear input shaft by a U-joint.

A toe plate bolts to the floor of the passenger compartment to cover the shaft opening and to protect the interior from noise, drafts, and dirt. ● **SEE FIGURE 115–15**. The toe plate has a tube for the intermediate shaft, and a seal and silencer fit on top of the tube.

Two sections at the upper end of the steering column house the column-mounted controls. ● **SEE FIGURE 115–16**. The lock housing, seated on top of the column jacket, is the topmost piece and contains the turn signal lever, hazard light control, and ignition lock. The gear selector lever and its housing are just below the lock housing, and the housing encases the top of the steering column jacket.

The lock housing contains the ignition lock cylinder, several electrical switches, and a steering shaft bearing. Some of the switches have driver-operated controls on the outside of the lock housing.

A multifunction switch operates the turn signals, the windshield wiper and washer switch, and the dimmer switch.

Most steering shafts ride on at least two bearings, one near the top and one near the bottom of the shaft, to allow the shaft to rotate freely without affecting other parts of the steering column. ● **SEE FIGURE 115–17**. A snap ring at the center of the bearing housing rests in a groove on the steering shaft to secure the bearing, and an O-ring on the steering shaft keeps lubricant in the bearing.

Underneath the bearing and housing is a **lock plate** and coil spring that lock the steering shaft into position when the driver removes the ignition key. ● **SEE FIGURE 115–18**. The ignition lock

cylinder, which is under the lock plate, moves a bellcrank that in turn operates a spring and lever assembly linked to the ignition switch actuating rod.

CONVENTIONAL STEERING GEARS

PURPOSE AND FUNCTION All steering gears have an input gear, which transmits rotary movement from the steering wheel into the steering gear, and an output gear, which causes the steering linkage to move laterally. The rotation of the steering wheel is transferred to the front wheels through a steering gear and linkage. The intermediate shaft is splined to a **worm gear** inside a conventional steering gear. Around the worm gear is a nut with gear teeth that meshes with the teeth on a section of a gear called a **sector gear**. The sector gear is part of a **pitman shaft**, also known as a **sector shaft**, as shown in ● **FIGURE 115–19**.

Ball, roller, or needle bearings support the sector shaft and the worm gear shaft, depending on the make and model of the gear assembly.

As the steering wheel is turned, the movement is transmitted through the steering gear to an arm attached to the bottom end of the pitman shaft. This arm is called the **pitman arm**. Whenever the steering wheel is turned, the pitman arm moves.

STEERING GEAR RATIO When the steering wheel is turned, the front wheels turn on their steering axis. If the steering wheel is rotated 20 degrees and results in the front wheels rotating 1 degree, then the steering gear ratio is 20:1 (read as "20 to 1"). ● **SEE FIGURE 115–20**. The front wheels usually are able to rotate through 60 to 80 degrees of rotation. The steering wheel, therefore, has to rotate 20 times the number of degrees that the wheels move.

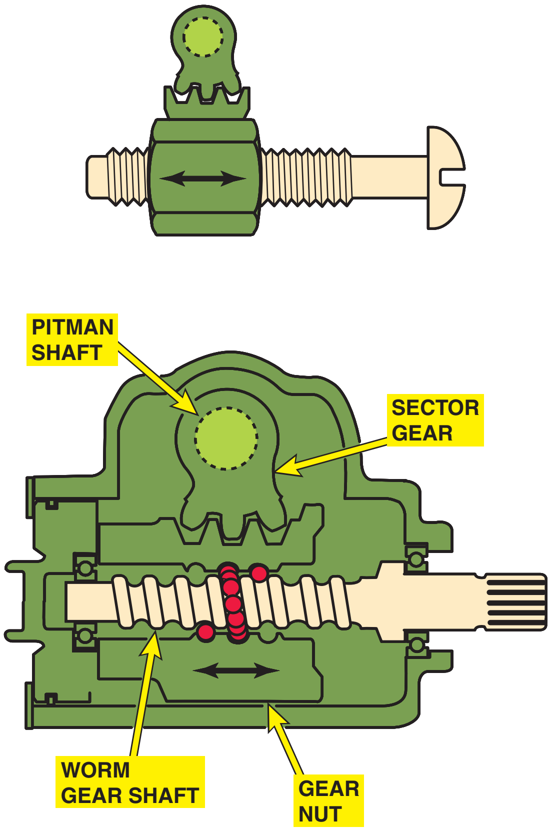

FIGURE 115–19 As the steering wheel is turned, the nut moves up or down on the threads, shown using a bolt to represent the worm gear and the nut representing the gear nut that meshes with the teeth of the sector gear.

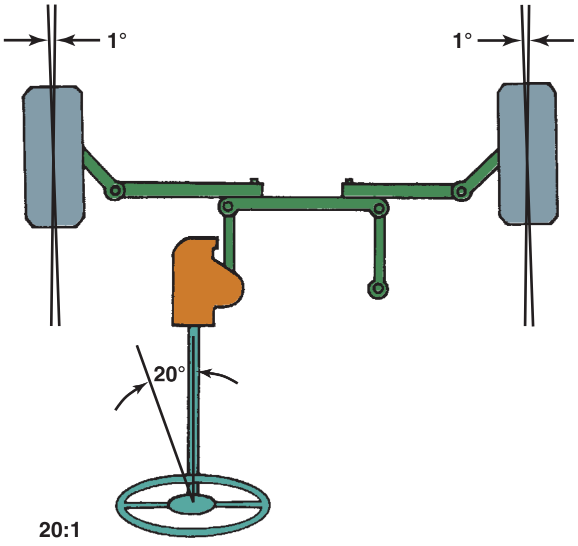

FIGURE 115–20 Steering gear ratio is the ratio between the number of degrees the steering wheel is rotated to the number of degrees the front wheel turns.

20 × 60 degrees = 1,200 degrees, or about three full revolutions (360 degrees = 1 full turn) of the steering wheel

20 × 80 degrees = 1,600 degrees, or over four revolutions of the steering wheel

A vehicle that turns three complete revolutions from full left to full right is said to have three turns "lock to lock."

A high ratio, such as 22 to 1 (22:1), means that the steering wheel must be rotated 22 degrees to move the front wheels 1 degree. This high ratio means that the steering wheel is easier to turn than a steering wheel with a lower ratio such as 14:1. The 14:1 ratio is considered to be "faster" than the 22:1 ratio. This fast ratio allows the front wheels to be turned with less movement of the steering wheel, yet more force may be required to turn the wheel. This is considered by some to be more "sporty."

Most steering gears and some rack-and-pinion steering gears feature a **variable ratio**. This feature causes the steering ratio to decrease as the steering wheel is turned from the on-center position. The high on-center ratio (such as 16:1) provides good steering feel at highway speeds while the reduced off-center ratio (13:1) provides fewer steering wheel turns during turning and parking. The ratio is accomplished by changing the length of the gear teeth on the sector gear. ● **SEE FIGURE 115–21** for an example of the teeth of a constant-ratio sector gear.

● **SEE FIGURE 115–22** for an example of the teeth on a variable-ratio sector gear.

The sector gear meshes with the ball nut inside the steering gear, as shown in ● **FIGURE 115–23**.

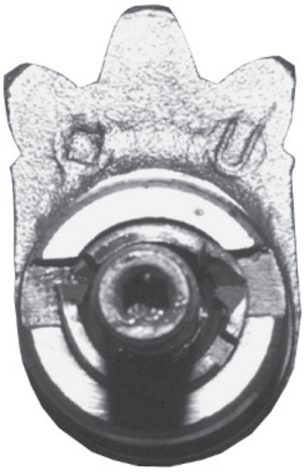

FIGURE 115–22 Variable-ratio steering gear sector shaft. Notice the larger center gear tooth.

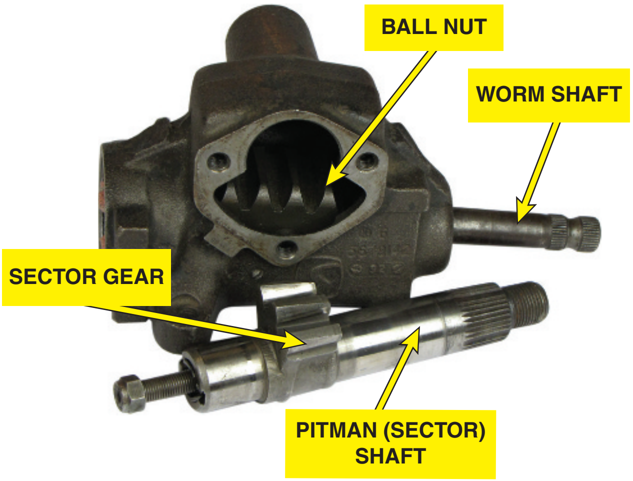

FIGURE 115–23 The sector gear meshes with the gear teeth on the ball nut.

RECIRCULATING BALL STEERING GEAR

PARTS AND OPERATION A recirculating ball steering gear is the most commonly used conventional steering gear. ● **SEE FIGURE 115–24**.

The end of the steering gear input shaft, or worm shaft, splines to the steering shaft U-joint and provides rotary input to the steering gear. An oil seal prevents fluid leakage where the input shaft enters the steering gear housing. At the top and the bottom of the worm gear are the upper and lower thrust bearings. The upper bearing cup seats in the housing, and the lower bearing cup seats in the adjuster plug. The thrust bearings reduce friction between the worm gear and the steering gear housing and control worm endplay.

The adjuster plug at the lower end of the worm gear holds the worm gear, shaft, and bearings inside the steering gear housing.

The ball nut, which has internal grooves that match the worm gear thread, fits over the worm gear. Steel balls roll through the tunnels formed by the ball nut grooves and the worm gear thread. Crescent-shaped ball-return guides link the ends of the ball-nut tunnels together, so the balls continuously circulate through the ball nut and worm gear, into the ball-return guides, and back again. A clamp secured by screws holds the return guides in place on one side of the ball nut. Gear teeth mesh with the teeth of the sector gear machined into the outside of the ball nut on the side opposite the ball-return guides.

The sector gear is an integral part of the sector shaft, which runs through the center of the sector gear, and forms the axis of the gear. One end of the sector shaft extends out of the steering gear housing and splines to the pitman arm. An oil seal prevents lubricant leakage where the sector shaft goes through the opening in the housing. To reduce friction, the sector shaft rides on two bushings. One bushing fits inside the housing and the other is part of the housing side cover. ● **SEE FIGURE 115–25**.

RACK-AND-PINION STEERING GEAR

PARTS AND OPERATION The term *rack and pinion* is simply a description of the basic design of this type of steering gear. The **rack-and-pinion** steering gear is widely used because it is light in weight and takes less space than a conventional steering gear. The input gear of a rack-and-pinion steering gear is a pinion gear that receives rotary input from the steering shaft. The rack is a rod with gear teeth machined into one side. The pinion gear teeth mesh with the teeth on the rack so that when the pinion gear turns, it pushes the rack from side to side. ● **SEE FIGURE 115–26**. The rack connects directly to the tie rod in the steering linkage to move the linkage back and forth in a straight line.

The steering gear input shaft is splined to the steering shaft U-joint. ● **SEE FIGURE 115–27**. At the end of the steering gear input shaft, which extends into the rack housing, is the pinion gear. Two ball bearings reduce friction between the shaft and the steering gear housing. The upper bearing is a press-fit on the input shaft, and the lower bearing installs inside the housing at the bottom of the pinion gear. A cover, which fits around the shaft and threads into the housing, seats on top of the upper ball bearing to preload it and close the top of the steering gear housing. An oil seal between the top cover and the input shaft keeps lubricant from leaking out of the housing. A lock nut holds the top cover in position.

The teeth of the pinion gear mesh with the teeth of the rack. The teeth are at one end of the rack and the pinion is offset at one side of the housing.

The rack is encased in the long, tubular steering gear housing with a mounting flange on the pinion end. Rubber bushings fit into the mounting flange bolt holes to absorb vibration and isolate the assembly from the frame.

A spring-loaded **rack support** and related hardware install through a hole at the back of the steering gear housing to position the rack. ● **SEE FIGURE 115–28**. The face of the rack support curves to match the back of the rack, which rests on it and slides back and forth across it. A spring behind the rack support cushions the rack from vibration and shocks. While the rack support provides a sliding surface to reduce friction at the pinion end of the rack, the rack rides in a bushing pressed into the steering gear housing at the opposite end to reduce friction.

Most rack-and-pinion units use a small metal tube running along the outside of the housing to connect the two boots and transfer air from one to the other. ● **SEE FIGURE 115–29**. If there

were no means for air displacement between the boots, they might collapse as they expanded or explode as they compressed.

Internal threads on each end of the rack allow attachment of the externally threaded tie rods.

A rubber boot at each side of the steering gear housing covers the end of the rack and the inner tie rod end to prevent dirt, water, and other contaminants from entering the assembly. Band clamps fasten the ends of the boots to the housing and tie rods.

The mounting points have rubber cushions to isolate the steering gear from shock and vibration. If the driver can feel vibration and road shocks through the steering wheel, the condition is called **kickback**. Kickback is most noticeable when driving into a curbed driveway.

CHAPTER QUIZ

1. The circuit to the airbag inflation module is connected from the steering column to the steering wheel through which component?
   - **a.** Slip ring and carbon brushes
   - **b.** Clockspring (coil)
   - **c.** Magnetic field sensor
   - **d.** Hall-effect switch
2. After removing the center nut, use a _______________ to remove the steering wheel from the steering shaft.
   - **a.** puller
   - **b.** hammer
   - **c.** shaft depressor
   - **d.** snap ring plier
3. Which part in the steering column allows for changes in the angle between the upper and lower shafts?
   - **a.** Flexible coupling
   - **b.** Column cover
   - **c.** Universal joint
   - **d.** Collapsible section
4. The rotation of the steering wheel causes which part to move the actual steering linkage in a conventional steering gear?
   - **a.** Sector shaft
   - **b.** Pitman arm
   - **c.** Worm gear
   - **d.** Gear nut
5. The driver rotates the steering wheel one-half of one revolution (180 degrees) on a vehicle equipped with a steering gear with a 20:1 gear ratio. How many degrees will the front wheels be rotated?
   - **a.** 9 degrees
   - **b.** 0.1 degree
   - **c.** 90 degrees
   - **d.** 11.1 degrees
6. What causes a variable-ratio steering gear to be able to change the ratio as the steering wheel is turned?
   - **a.** Using two or three different sector gears depending on design
   - **b.** Using a variable-length pitman arm
   - **c.** Changing the number of teeth on the worm gear
   - **d.** Changing the length of the teeth on the sector gear
7. The sector shaft used in most conventional steering gears rides on two bushings in order to _______________.
   - **a.** provide for a variable ratio
   - **b.** keep the steering wheel centered
   - **c.** reduce friction
   - **d.** help provide feedback to the driver regarding the road surface
8. The steering wheel is attached to the steering shaft using a _______________.
   - **a.** bolt and clamp
   - **b.** bolt or nut
   - **c.** clockspring
   - **d.** snap-ring
9. On a rack-and-pinion steering gear, the inner tie rods are protected by _______________.
   - **a.** boots
   - **b.** gaskets
   - **c.** O-rings
   - **d.** flanges
10. What is the purpose and function of the air tube connecting the two end boots?
    - **a.** To transfer air from one boot to the other when the wheels are turned
    - **b.** To move grease from one boot to the other to equalize the amount of grease in each boot
    - **c.** To prevent water from entering the boots
    - **d.** To keep any fluid from escaping

STEERING LINKAGE AND SERVICE

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Identify steering linkage components.
- Describe rack-and-pinion inner tie rod ends.
- Describe four-wheel steering systems.
- Discuss steering linkage lubrication.
- Describe the purpose and procedure for performing a dry park test.
- Describe the steps for under-vehicle inspection of steering systems.
- Explain how to replace steering linkage parts.

KEY TERMS:

STEERING LINKAGE

PURPOSE AND FUNCTION The steering linkage relays steering forces from the steering gear to the front wheels. Most conventional steering linkages use the **parallelogram-type** design. A parallelogram is a geometric box shape where opposite sides are parallel and equal distance. A parallelogram-type linkage uses four **tie rods**, two inner and two outer (left and right), a **center link** (between the tie rods), and an idler arm on the passenger side and a **pitman arm** attached to the steering gear output shaft (pitman shaft). ● **SEE FIGURE 116–1**.

As the steering wheel is rotated, the pitman arm is moved. The pitman arm attaches to a center link. At either end of the center link are inboard (inner) tie rods, adjusting sleeves, and outboard (outer) tie rods connected to the steering arm, which moves the front wheels. The passenger side of all these parts is supported and held horizontal by an idler arm that is bolted to the frame. The center link may be known by several names, including the following:

- Center link
- Connecting link
- Connecting rod
- Relay rod
- Intermediate rod
- Drag link (usually a truck term only)

Other types of steering linkages often used on light trucks and vans include the **cross-steer linkage**. ● **SEE FIGURE 116–2** for a comparison of parallelogram and cross-steer-type steering linkage arrangements.

NOTE: Many light trucks, vans, and some luxury cars use a steering dampener attached to the linkage. A steering dampener is similar to a shock absorber, and it absorbs and dampens sudden motions in the steering linkage. ● SEE FIGURE 116–3.

FREQUENTLY ASKED QUESTION

Why Is a Grease Fitting Sometimes Called a Zerk Fitting?

In 1922, the *zerk* fitting was developed by Oscar U, Zerk, an employee of the Alemite Corporation, a manufacturer of pressure lubrication equipment. A zerk or grease fitting is also known as an *Alemite fitting.*

The idler arm supports the passenger side of the center link and keeps the steering linkage level with the road. This type of linkage is called a parallelogram-type design.

FIGURE 116–2 The most common type of steering is the parallelogram. The cross-steer and Haltenberger linkage designs are used on some trucks and vans.

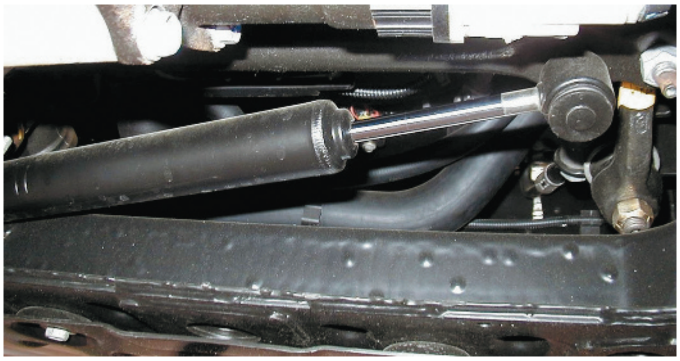

FIGURE 116–3 Typical steering dampener used on a Hummer H2.

Connections between all steering component parts are constructed of small ball-and-socket joints. These joints allow side-to-side movement to provide steering of both front wheels, and allow the joints to move up and down, which is required for normal suspension travel.

It is important that all of these joints be lubricated with chassis grease through a **grease fitting**, also called a **zerk fitting**, at least every six months or per the vehicle manufacturer's specifications.

Some vehicles come equipped with sealed joints and do not require periodic servicing. Some vehicles come from the factory with plugs that need to be removed and replaced with grease fittings and then lubricated.

TIE ROD ENDS Tie rod ends connect the steering linkage to the steering knuckles and to other steering linkage components. Conventional tie rod ends use a hardened steel ball stud assembled into a hardened steel and thermoplastic bearing. An internal preload spring limits the ball stud endplay and helps compensate for ball-and-socket wear. ● **SEE FIGURE 116–4** for two designs of tie rod ends.

For many years, Ford Motor Company used tie rod ends that included a rubber-bonded steel ball stud. Because there is no sliding friction inside the tie rod end, no lubrication was needed. This type of tie rod end is called **RBS (rubber-bonded socket)**. ● **SEE FIGURE 116–5**.

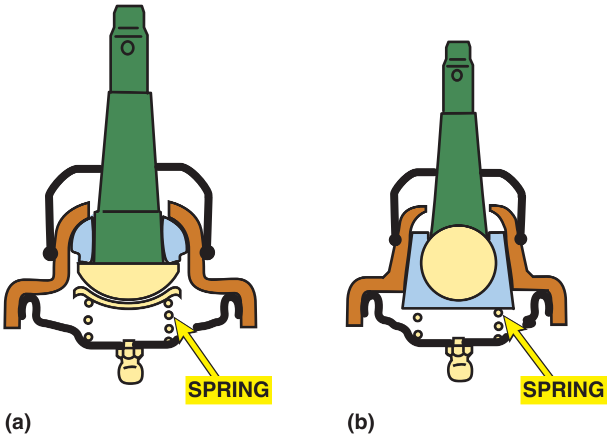

FIGURE 116–4 (a) A dual bearing design with a preload spring. The use of two bearing surfaces allows one surface for rotation (for steering) and another surface for pivoting (to allow for suspension up-and-down movement). (b) The nylon wedge bearing type allows for extended lube intervals. Wear is automatically compensated for by the tapered design and spring-loaded bearing.

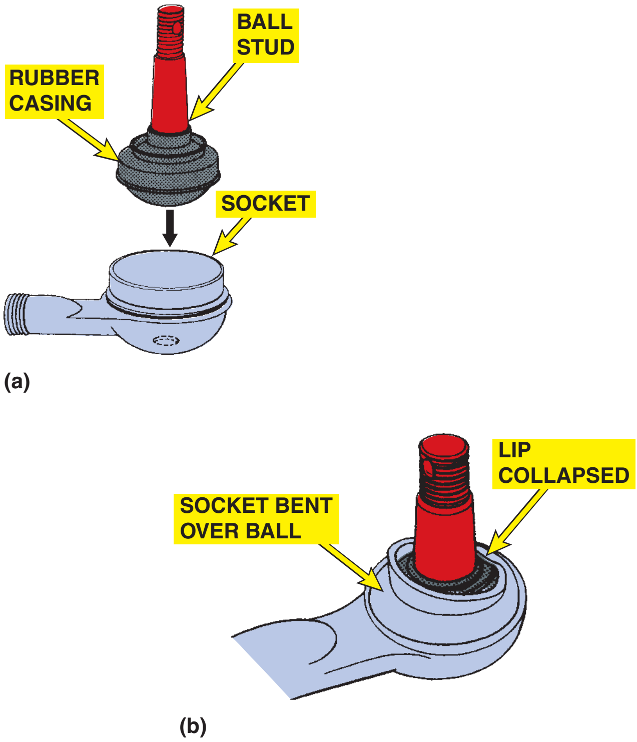

FIGURE 116–5 (a) A rubber-bonded socket is constructed of a rubber casing surrounding the ball stud, which is then inserted into the socket of the tie rod end. The hole in the socket allows air to escape as the ball stud is installed and there is not a place for a grease fitting. (b) The socket is crimped over the ball so that part of the socket lip retains the stud.

RACK-AND-PINION INNER TIE ROD ENDS

TERMINOLOGY Inner tie rod end assemblies used on rack-and-pinion steering units require special consideration and often special tools. The inner tie rod end is also called a **ball socket assembly**.

The inner tie rod assemblies are attached to the end of the steering rack by one of several methods. ● **SEE FIGURE 116–6**.

STAKED This method is common on Saginaw-style rack-and-pinion steering units found on General Motors vehicles.

The flange around the outer tie rod must be restaked to the flat on the end of the rack.

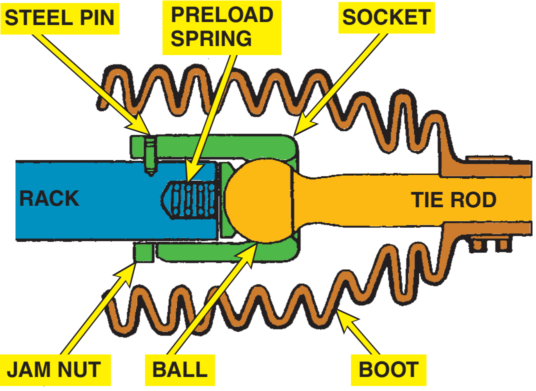

FIGURE 116–6 Rack-and-pinion steering systems use a ball-and-socket-type inner tie rod end.

RIVETED OR PINNED This method is commonly found on Ford vehicles. Some roll pins require a special puller, or the pin can be drilled out. Many styles use an aluminum rivet. A special, very deep socket or a large open-end wrench can usually be used to shear the aluminum rivet by unscrewing the socket assembly from the end of the rack while the rack-and-pinion unit is still in the vehicle. ● **SEE FIGURE 116–7**.

CENTER TAKE-OFF RACKS For the **center take-off racks**, use bolts to secure the inner tie rods to the rack, as shown in ● **FIGURE 116–8**.

FRONT STEER VERSUS REAR STEER **Front steer**, also called *forward steer*, is the term used to describe a vehicle that has the steering gear in front of the front wheel centerline. Having the steering gear located in this position improves handling and directional stability, especially when the vehicle is heavily loaded.

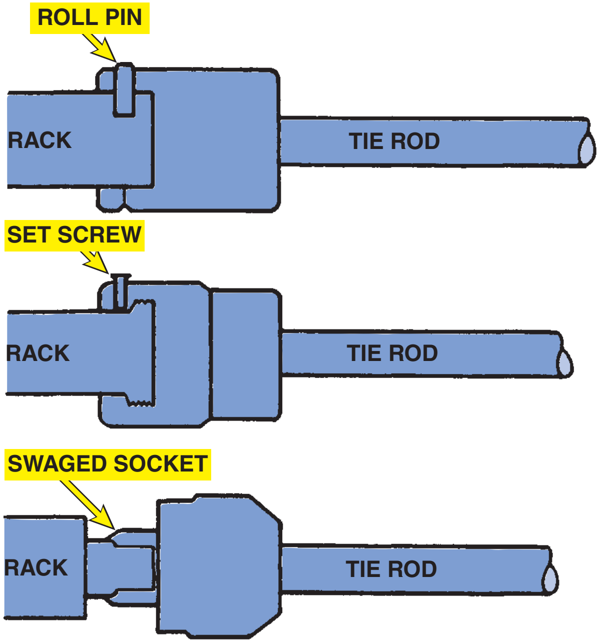

FIGURE 116–7 A variety of methods are used to secure the inner tie rod end socket assembly to the end of the rack.

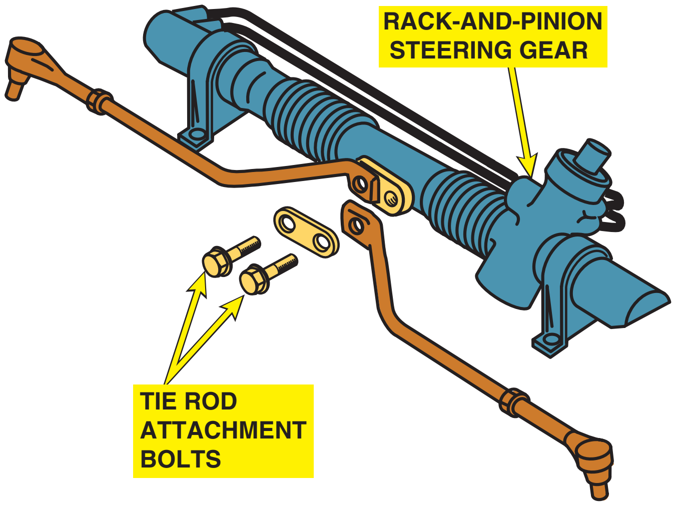

FIGURE 116–8 Exploded view of a center-take-off-style rack-and-pinion steering gear assembly.

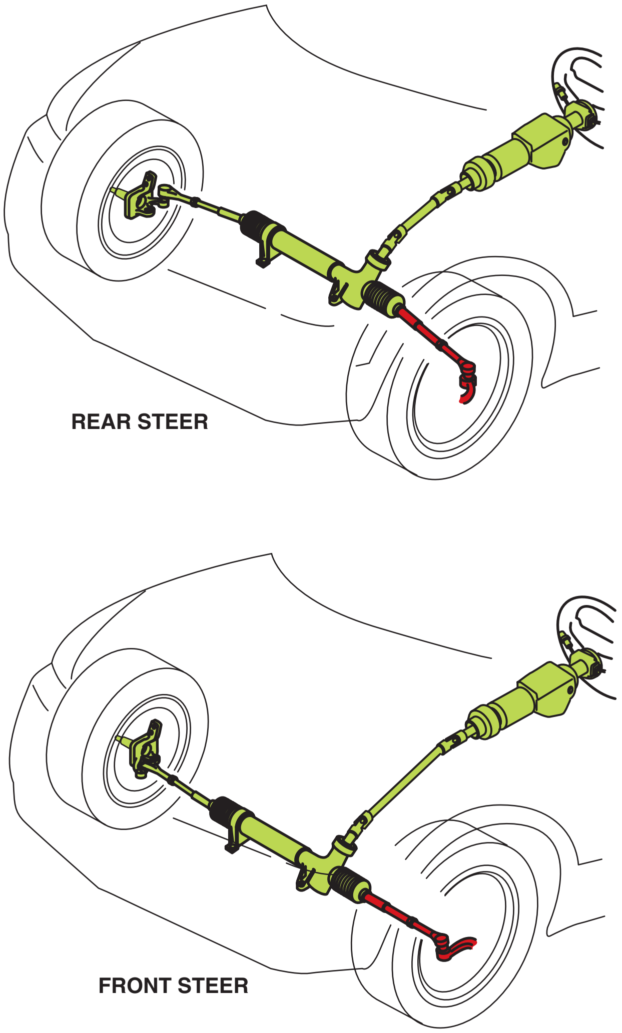

FIGURE 116–9 In a rear-steer vehicle, the steering linkage is behind the centerline of the front wheels, whereas the linkage is in front on a front-steer vehicle.

Front-steer vehicles usually produce an understeer effect that makes the vehicle feel very stable while cornering. If the steering gear linkage is located behind the wheels, it is called **rear steer** and the cornering forces are imposed on the steering in the direction of the turn. This is an oversteer effect. It tends to make the steering easier and makes the vehicle feel less stable.

Most front-wheel-drive vehicles are rear steering, with the rack-and-pinion steering unit attached to the bulkhead or sub-frame behind the engine. ● **SEE FIGURE 116–9**.

FOUR-WHEEL STEERING SYSTEMS

TERMINOLOGY Some vehicles were equipped with a system that steers all four wheels. Two terms are commonly used when discussing four-wheel steering:

1. **Same-phase steering**. **Same-phase steering** means that the front and rear wheels are steered in the same direction. Same-phase steering improves steering response, especially during rapid-lane-change-type maneuvers.
2. **Opposite-phase steering.** Also called *negative-phase mode*, **opposite-phase steering** is when the front wheels

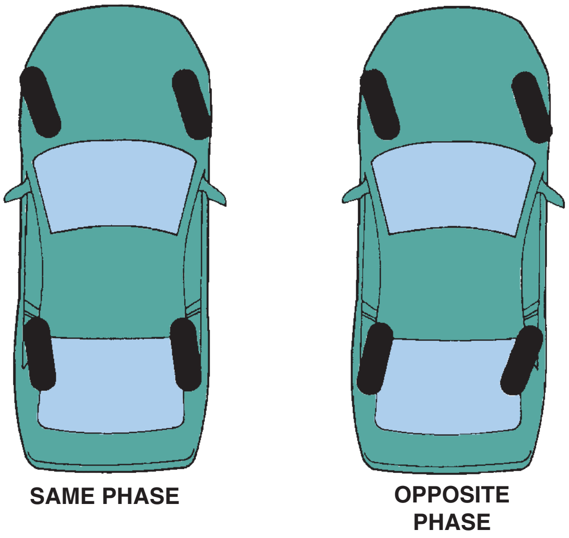

FIGURE 116–10 Opposite-phase four-wheel steer is usually used only at low vehicle speed to help in parking maneuvers. Same-phase steering helps at higher speeds and may not be noticeable by the average driver.

and rear wheels are steered in the opposite direction. ● **SEE FIGURE 116–10**. Opposite-phase steering will quickly change the vehicle's direction, but may cause a feeling of oversteering.

Opposite-phase steering is best at low speeds; same-phase steering is best for higher-speed handling and lane-change maneuvers.

STEERING LINKAGE LUBRICATION

Keeping all joints equipped with a grease fitting properly greased is necessary for long life and ease of steering. ● **SEE FIGURE 116–11**.

During a chassis lubrication, do not forget to put grease on the *steering stop,* if so equipped. **Steering stops** are the projections or built-up areas on the control arms of the front suspension designed to limit the steering movement at full lock. ● **SEE FIGURE 116–12**.

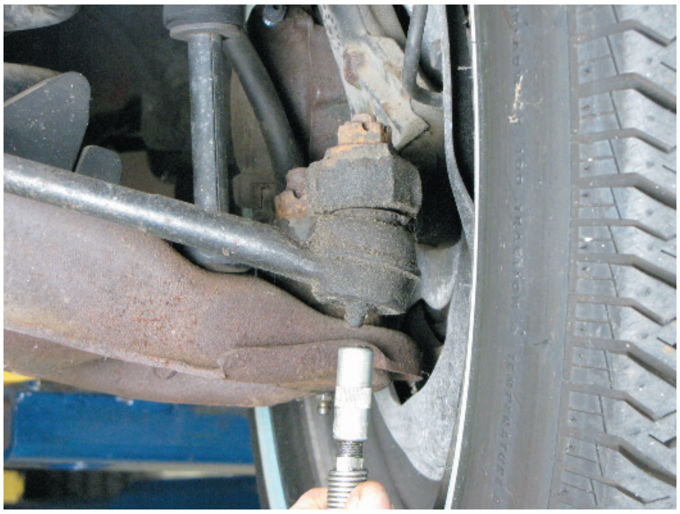

FIGURE 116–11 Greasing a tie rod end. Some joints do not have a hole for excessive grease to escape, and excessive grease can destroy the seal.

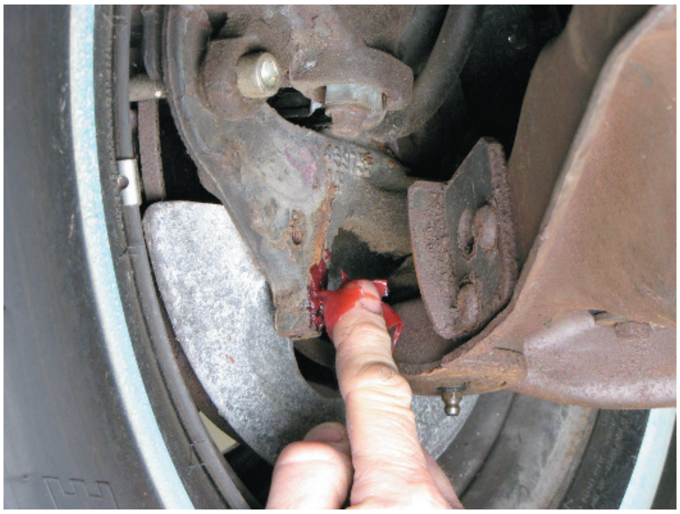

FIGURE 116–12 Part of steering linkage lubrication is applying grease to the steering stops. If these stops are not lubricated, a grinding sound may be heard when the vehicle hits a bump when the wheels are turned all the way one direction or the other. This often occurs when driving into or out of a driveway that has a curb.

When the steering wheel is turned as far as it can go, the steering should *not* stop inside the steering gear. Forces exerted by the power steering system can do serious damage to the steering gear if absorbed by the steering gear rather than the steering stop.

NOTE: Many rack-and-pinion steering units are designed with a rack-travel-limit internal stop and do not use an external stop on the steering knuckle or control arm.

Most steering stops are designed so that the lower control arm hits a small section of the body or frame when the steering wheel is turned to the full "lock" position. Steering stops should be lubricated to prevent a loud grinding noise when turning while the vehicle is going over a bump. This noise is usually noticeable when turning into or out of a driveway.

DRY PARK TEST

PURPOSE Since many steering (and suspension) components do *not* have exact specifications for replacement purposes, it is extremely important that the beginning service technician work closely with an experienced veteran technician. While most technicians can determine when a steering component such as a tie rod end is definitely in need of replacement, marginally worn parts are often hard to spot and can lead to handling problems. One of the most effective, yet easy to perform, steering component inspection methods is called the **dry park test**.

Excessive play in the steering wheel can be caused by worn or damaged steering components. Looseness in the steering components usually causes freeplay in the steering wheel. Freeplay refers to the amount of movement of the steering wheel required to cause movement of the front wheels. The exact cause of freeplay in the steering should be determined if the freeplay exceeds 2 inch (5 cm) for parallelogram-type steering

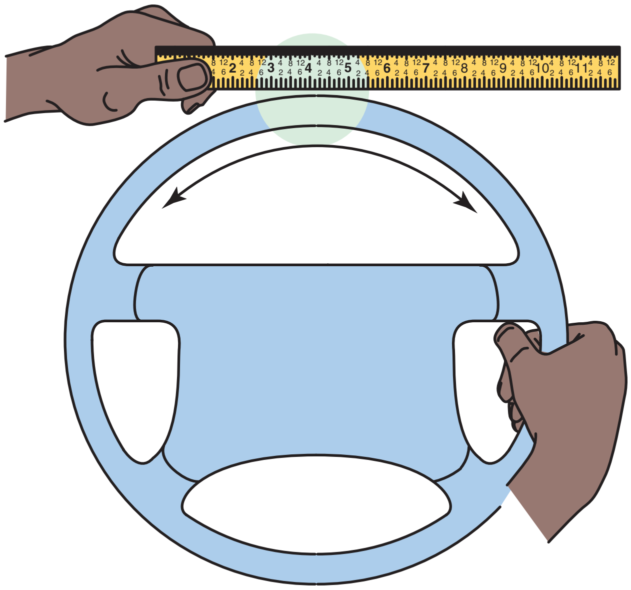

FIGURE 116–13 Checking for freeplay in the steering.

linkages, or 3/8 inch (1 cm) for rack-and-pinion steering. ● **SEE FIGURE 116–13**.

This simple test is performed with the vehicle on the ground or on a drive-on ramp-type hoist, moving the steering wheel back and forth *slightly* while an assistant feels for movement at each section of the steering system. The technician can start checking for any looseness in the steering linkage starting either at the outer tie rod ends and working toward the steering column, or from the steering column toward the outer tie rod ends. It is important to check each and every joint and component of the steering system, including the following:

1. The intermediate shaft and flexible coupling.
2. All steering linkage joints, including the inner tie rod end ball socket. ● **SEE FIGURE 116–14**.
3. Steering gear mounting and rack-and-pinion mounting bushings.

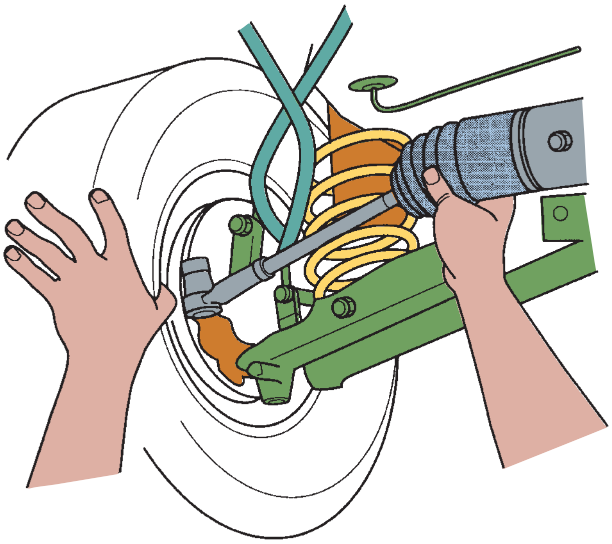

FIGURE 116–14 All joints should be felt during a dry park test. Even inner tie rod ends (ball socket assemblies) can be felt through the rubber bellows on many rack-and-pinion steering units.

FREQUENTLY ASKED QUESTION

Why Do Only a Few Vehicles Use Grease Fittings?

Many years ago, all vehicles were equipped with grease fittings, while today very few vehicles are so equipped. The reasons for this, as given by engineers, include the following:

- It has been determined that the use of the wrong type of grease can cause more harm than good.
- If a grease fitting is used to allow grease to enter the suspension or steering joint, then water can also get inside the joint.
- Grease fittings are often ignored or the greasing of the joint is not performed by the service technician.
- Low-friction joints do not require routine service like the older metal-to-metal joints required.

TECH TIP

Jounce/Rebound Test

All steering linkage should be level and "work" at the same angle as the suspension arms, as shown in ● **FIGURE 116–15**. A simple test to check these items is performed as follows:

1. Park on a hard, level surface with the wheels straight ahead and the steering wheel in the *unlocked* position.
2. Bounce (jounce) the vehicle up and down at the front bumper while watching the steering wheel.

The steering wheel should *not* move during this test. If the steering wheel moves while the vehicle is being bounced, look for a possible bent steering linkage, suspension arm, or steering rack. ● **SEE FIGURE 116–16**.

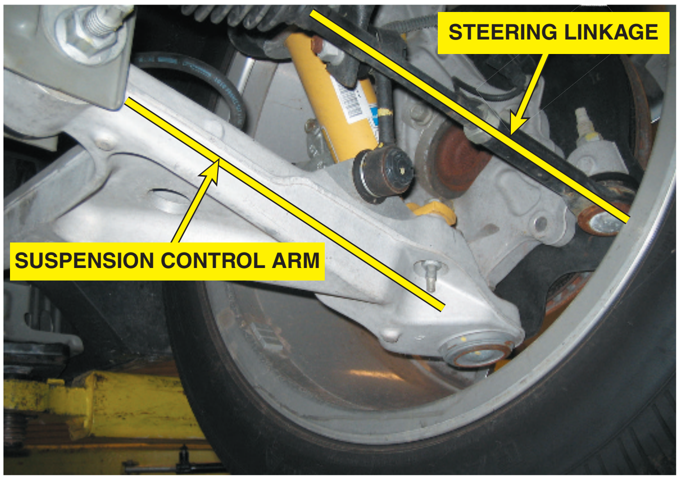

FIGURE 116–15 The steering and suspension arms must remain parallel to prevent the up-and-down motion of the suspension from causing the front wheels to turn inward or outward.

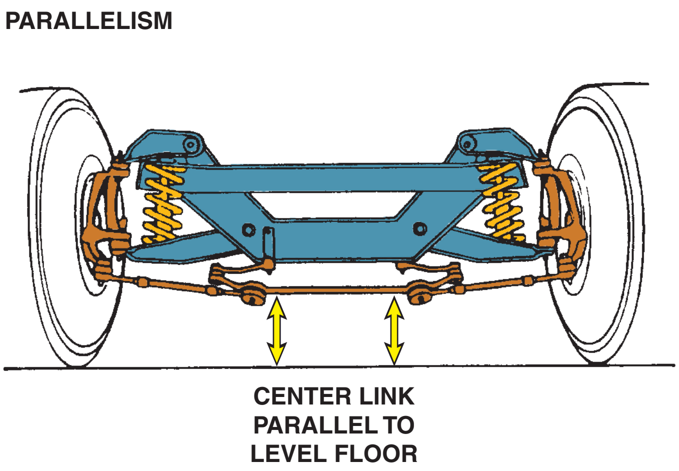

FIGURE 116–16 The center link should be parallel to the ground.

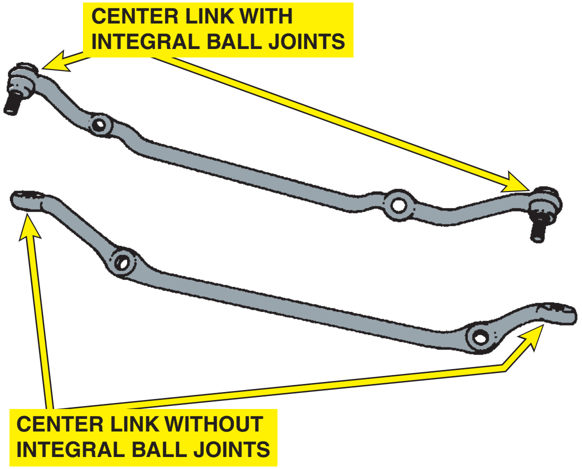

FIGURE 116–17 Some center links have ball joints while others have tapered socket holes to accept ball joints on the pitman arm, idler arm, and inner tie rod ends.

TECH TIP

Wear and Nonwear Center Links

Some center links are equipped with ball-and-socket joints, which can wear. Other center links are manufactured with holes for ball-joint studs only. ● **SEE FIGURE 116–17**. Generally, the center links that do not use joints are unlikely to need replacement unless a joint becomes loose and wears the tapered stud hole. Knowing which style of center link is used will help determine the most likely location to check for excessive steering linkage play.

UNDER-VEHICLE INSPECTION

After checking the steering system components as part of a dry park test, hoist the vehicle and perform a thorough part-by-part inspection:

1. Inspect each part for damage due to an accident or bent parts due to the vehicle hitting an object in the roadway.

CAUTION: Never straighten a bent steering linkage; always replace with new parts.

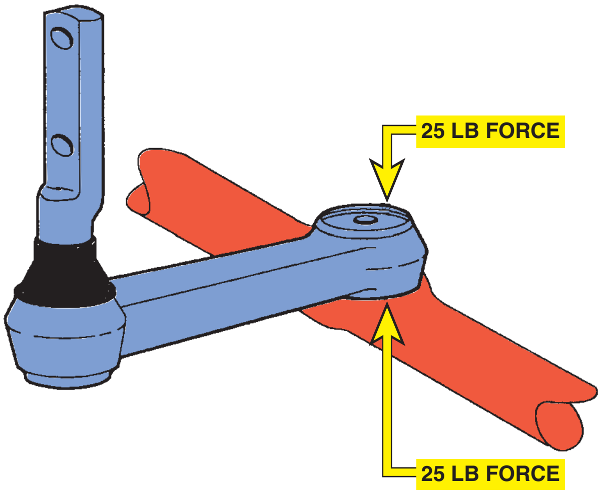

FIGURE 116–18 To check an idler arm, most vehicle manufacturers specify that 25 pounds of force be applied by hand up and down to the idler arm. The idler arm should be replaced if the total movement (up and down) exceeds 1/4 inch (6 mm).

2. Idler arm inspection is performed by using *hand* force of 25 pounds (110 N-m) up and down on the arm. If the *total* movement exceeds 1/4 inch (6 mm), the idler arm should be replaced. ● **SEE FIGURE 116–18**.
3. All other steering linkage should be tested *by hand* for any vertical or side-to-side looseness. Tie rod ends use ball-and-socket joints to allow for freedom of movement for suspension travel and to transmit steering forces to the front wheels. It is therefore normal for tie rods to rotate in their sockets when the tie rod sleeve is rocked. **Endplay in any tie rod should be zero**. Many tie rods are spring loaded to help keep the ball-and-socket joint free of play as the joint wears. Eventually, the preloaded spring cannot compensate for the wear, and endplay occurs in the joint. ● **SEE FIGURES 116–19 AND 116–20**.
4. All steering components should be tested with the wheels in the straight-ahead position. If the wheels are turned, some apparent looseness may be noticed due to the angle of the steering linkage.

CAUTION: Do not turn the front wheels of the vehicle while suspended on a lift to check for looseness in the steering linkage. The extra leverage of the wheel and tire assembly can cause a much greater force to be applied to the steering components than can be exerted by hand alone. This extra force may cause some apparent movement in good components that may not need replacement.

TECH TIP

The Killer Bs

The "three Bs" that can cause steering and suspension problems are bent, broken, or binding components. Always inspect each part under the vehicle for each of the killer Bs.

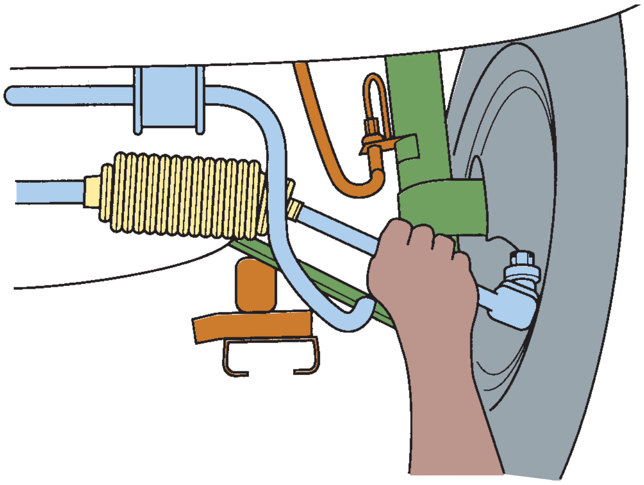

FIGURE 116–19 Steering system component(s) should be replaced if any noticeable looseness is detected when moved by hand.

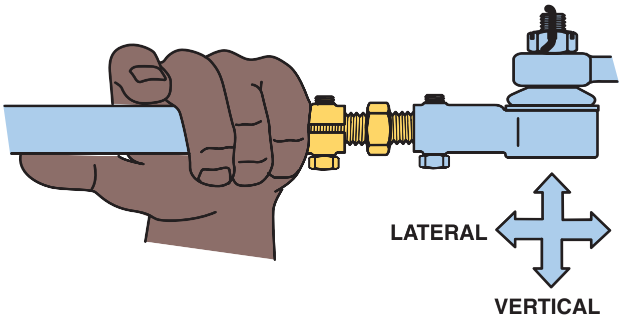

FIGURE 116–20 All joints should be checked by hand for any lateral or vertical play.

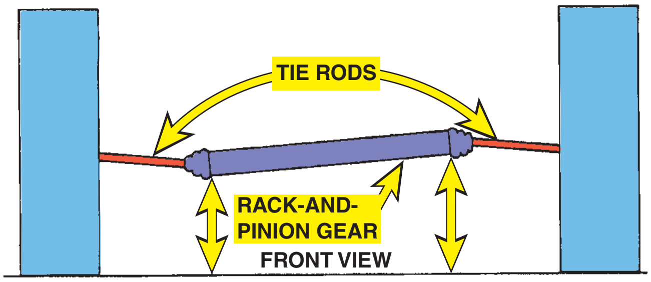

FIGURE 116–21 If a rack-and-pinion or any other steering linkage system is not level, the front tires will be moved inward and/or outward whenever the wheels of the vehicle move up or down.

STEERING LINKAGE REPLACEMENT

PARALLELOGRAM TYPE When replacing any steering system component, it is best to replace all defective and marginally good components at the same time. Use the following guidelines.

Parts that can be replaced *individually* include the following:

Idler arm
Center link
Pitman arm
Intermediate shaft
Intermediate shaft U-joint

CASE STUDY

Bump Steer

Bump steer, or orbital steer, is used to describe what happens when the steering linkage is not level. The front tires turn inward or outward as the wheels and suspension move up and down. (Automotive chassis engineers call it roll steer.) The vehicle's direction is changed without moving the steering wheel whenever the tires move up and down over bumps, dips in the pavement, or even over gentle rises!

This author experienced bump steer once and will never forget the horrible feeling of not having control of the vehicle. After replacing an idler arm and aligning the front wheels, everything was normal until about 40 MPH (65 km/h); then the vehicle started darting from one lane of the freeway to another. Because there were no "bumps" as such, bump steer was not considered as a cause. Even when holding the steering wheel perfectly still and straight ahead, the vehicle would go left, then right. Did a tie rod break? It certainly felt exactly like that's what happened. I slowed down to below 30 MPH and returned to the shop.

After several hours of checking everything, including the alignment, I discovered that the idler arm was not level with the pitman arm. This caused a pull on the steering linkage whenever the suspension moved up and down. As the suspension compressed, the steering linkage pulled inward on the tie rod on that side of the vehicle. As the wheel moved inward (toed in), it created a pull just as if the wheel were turned by the driver.

This is why all steering linkages must be parallel with the lower control. The reason for the bump steer was that the idler arm was bolted to the frame, which was slotted vertically. I didn't pay any attention to the location of the original idler arm and simply bolted the replacement to the frame. After raising the idler arm back up where it belonged (about 1/2 inch [13 mm]), the steering problem was corrected.

Other common causes of bump steer are worn or deteriorated rack mounting bushings, a noncentered steering linkage, or a bent steering linkage. If the steering components are not level, any bump or dip in the road will cause the vehicle to steer one direction or the other. ● **SEE FIGURE 116–21**.

Summary:

Complaint—Driver complained that the vehicle pulled to one lane and then the other when driving over a rough section of road.

Cause—The idler arm was not installed in the correct location to prevent bump steer.

Correction—The idler arm was installed correctly and the bump steer was corrected.

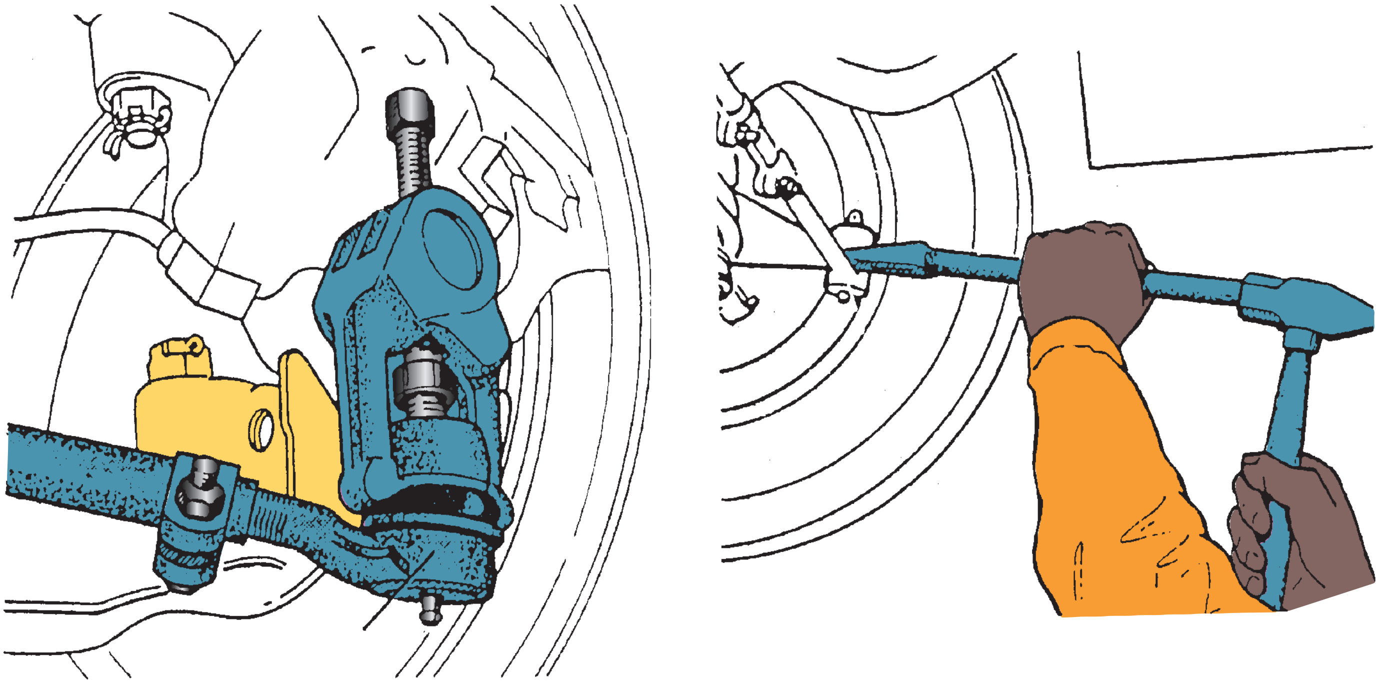

FIGURE 116–22 The preferred method for separating the tie rod end from the steering knuckle is to use a puller such as the one shown. A pickle-fork-type tool should only be used if the tie rod end is going to be replaced. A pickle-fork-type tool can damage or tear the rubber grease boot.

Parts that should be replaced in *pairs only* include the following:

Outer tie rod ends

Inner tie rod ends

Idler arm (if there are two on the same vehicle, such as GM's Astro van)

Replacing steering system components involves these steps:

STEP 1 Hoist the vehicle safely with the wheels in the straight-ahead position. Remove the front wheels, if necessary, to gain access to the components.

STEP 2 Loosen the retainer nut on tapered components, such as tie rod ends. Use a tie rod removal puller (also called a *taper breaker*), as shown in ● **FIGURE 116–22** or use hammers to slightly deform the taper, as shown in ● **FIGURE 116–23**.

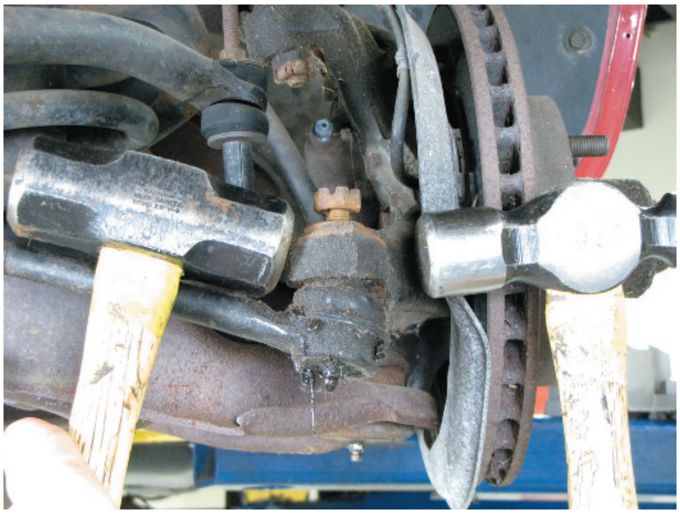

FIGURE 116–23 Two hammers being used to disconnect a tie rod end from the steering knuckle. One hammer is used as a backing for the second hammer. Notice that the attaching nut has been loosened, but not removed. This prevents the tie rod end from falling when the tapered connection is knocked loose.

CAUTION: Vehicle manufacturers often warn not to use a tapered pickle-fork tool to separate tapered parts. The wedge tool can tear the grease seal and damage both the part being removed and the adjoining part.

Pitman arms require a larger puller to remove the pitman arm from the splines of the pitman shaft. ● **SEE FIGURES 116–24 AND 116–25**.

STEP 3 Replace the part using the hardware and fasteners supplied with the replacement part. *Do not reuse the precrimped prevailing torque nuts used at the factory as original equipment on many tie rod ends*.

CAUTION: Whenever tightening the nuts of tapered parts such as tie rods, *DO NOT* loosen after reaching the proper

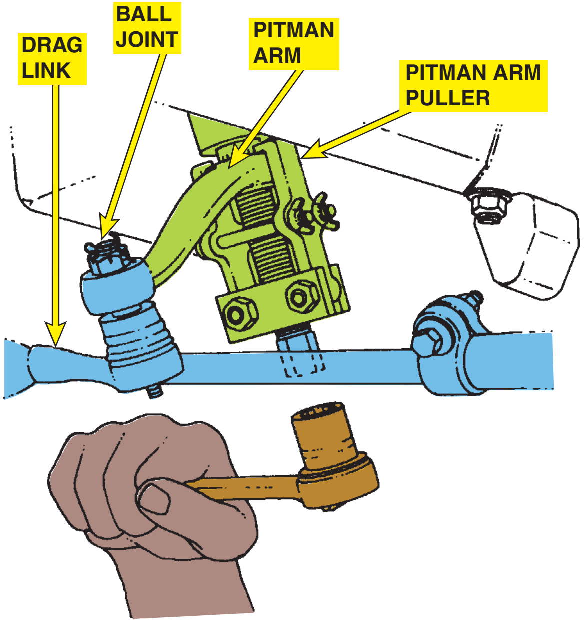

FIGURE 116–24 A pitman arm puller is used to remove the pitman arm from the pitman shaft.

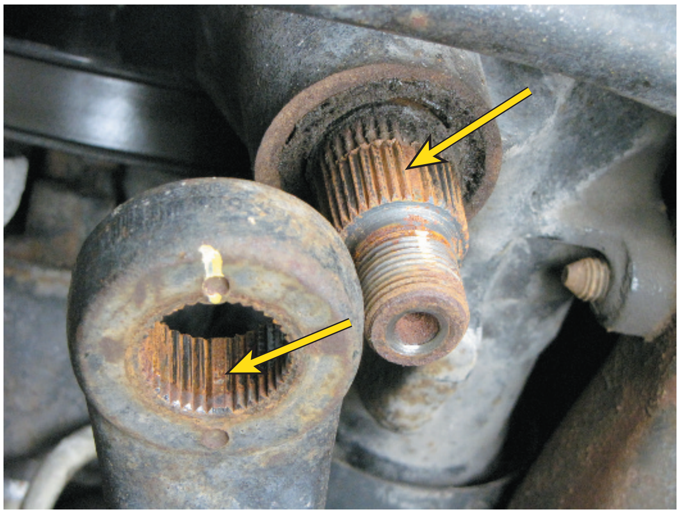

FIGURE 116–25 Pitman arm and pitman shaft indexing splines.

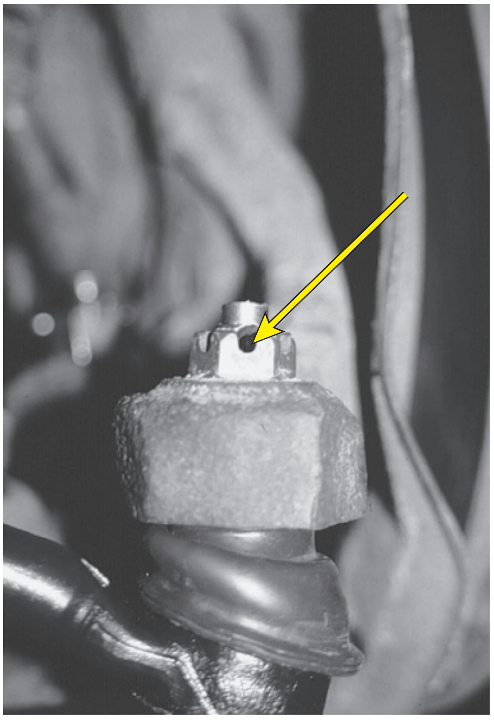

FIGURE 116–26 Align the hole in the tie rod end with the slot in the retaining nut. If the holes do not line up, always tighten the nut farther (never loosen) until the hole lines up.

assembly torque to align the cotter key hole. If the cotter key does not fit, *tighten* the nut farther until the hole lines up for the cotter key. ● SEE FIGURE 116–26. Always use a new cotter key.

When replacing tie rod ends, use the adjusting sleeve to adjust the total length of the tie rod to the same position and length as the original. Measure the original length of the tie rods and assemble the replacement tie rod(s) to the same overall length. ● **SEE FIGURE 116–27**.

When positioning the tie rod end(s), check that the stud is centered in the socket, as shown in ● **FIGURE 116–28**. This permits maximum steering linkage movement without getting into a bind if the steering linkage is pivoted beyond the angle the tie rod end can move in the socket.

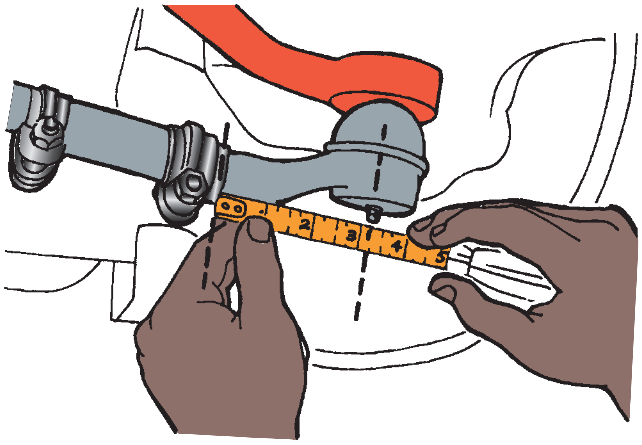

FIGURE 116–27 Replacement tie rods should be of the same overall length as the originals. Measure from the edge of the tie rod sleeve to the center of the grease fitting. When the new tie rod is threaded to this dimension, the toe setting will be close to the original.

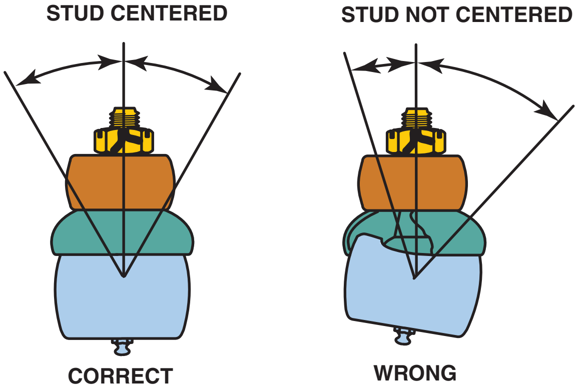

FIGURE 116–28 All tie rod ends should be installed so that the stud is in the center of its operating range, as shown.

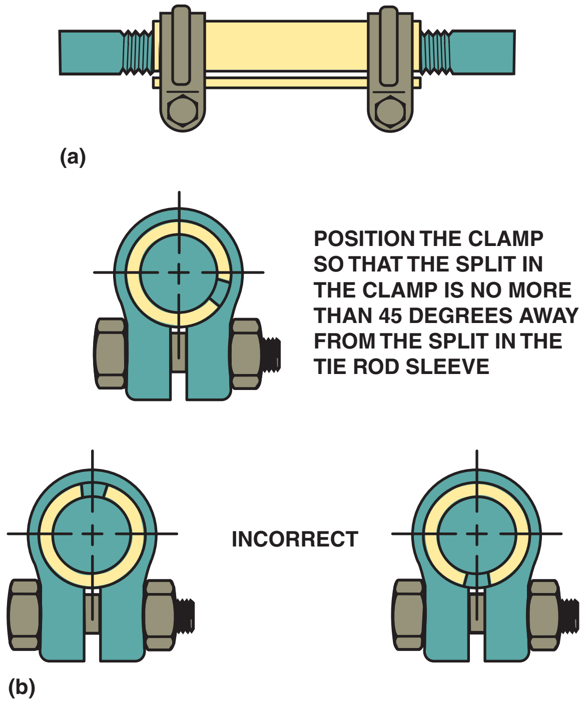
NOTE: To ensure proper wheel alignment, install the adjusting sleeve with an equal number of threads showing at each end of the sleeve. Some manufacturers also specify a *minimum* of three threads showing at each end. If the sleeve itself is corroded or bent, it should be replaced along with either or both of the tie rod ends (inner and outer). ● SEE FIGURE 116–29.

SERVICE OF BALL SOCKET ASSEMBLIES Inner tie rod end assemblies used on rack-and-pinion steering units require special consideration and often special tools. The inner tie rod end, also called a ball socket assembly, should be replaced whenever there is any noticeable freeplay in the ball-and-socket joint. Another test of this joint is performed by disconnecting the outer tie rod end and measuring the effort required to move the tie rod in the socket, as shown in ● **FIGURE 116–30**. This is called the **articulation test**.

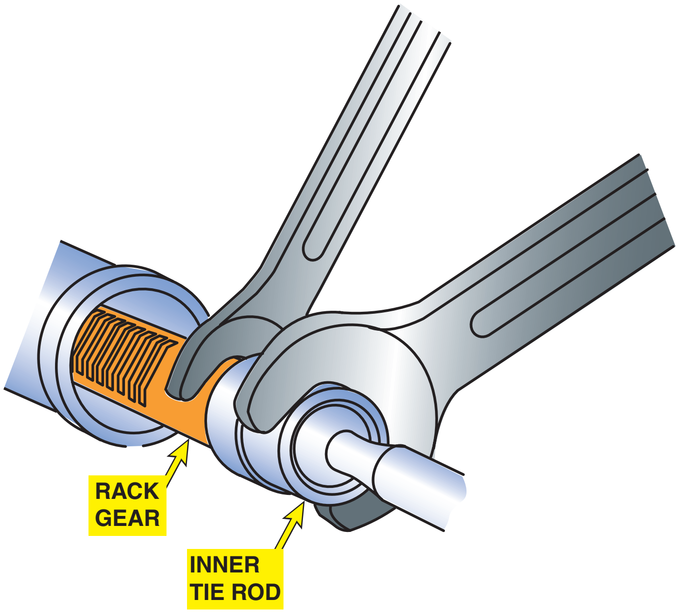
NOTE: The articulation test is to be used on metal-tometal ball socket assemblies. Low-friction joints (polished ball and plastic liner-type joints) may require less effort to move and still be serviceable.

The inner tie rod assemblies are attached to the end of the steering rack by one of several methods.



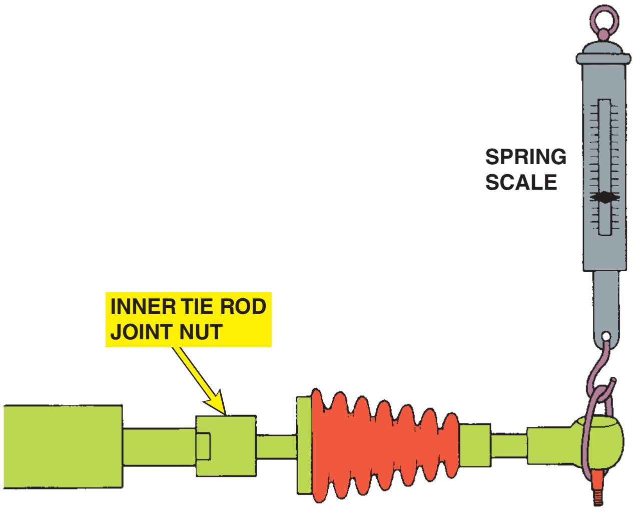
(a)
POSITION THE CLAMP SO THAT THE SPLIT IN THE CLAMP IS NO MORE THAN 45 DEGREES AWAY FROM THE SPLIT IN THE TIE ROD SLEEVE
INCORRECT
(b)

FIGURE 116–29 (a) Tie rod adjusting sleeve. (b) Be sure to position the clamp correctly on the sleeve.



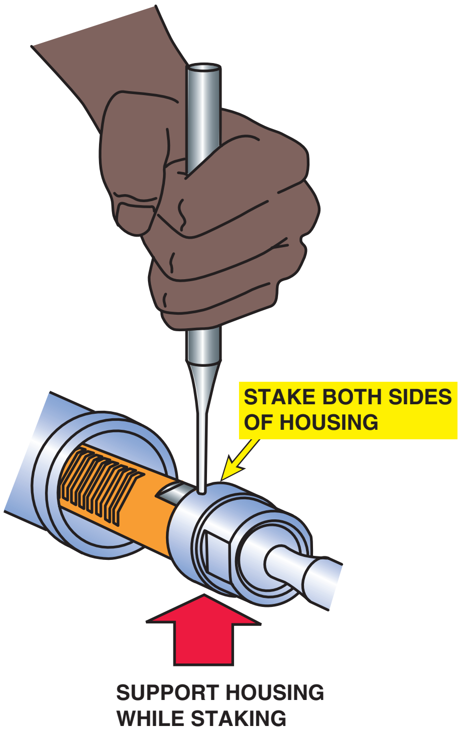
RACK GEAR
INNER TIE ROD

FIGURE 116–31 Removing a staked inner tie rod assembly requires two wrenches—one to hold the rack and the other to unscrew the joint from the end of the steering rack.



SPRING SCALE
INNER TIE ROD JOINT NUT

FIGURE 116–30 An articulation test uses a spring scale to measure the amount of force needed to move the tie rod in the ball socket assembly. Most manufacturers specify a minimum of 1 pound (4.4 N) of force and a maximum of 6 pounds (26 N).



STAKE BOTH SIDES OF HOUSING
SUPPORT HOUSING WHILE STAKING

FIGURE 116–32 When the inner tie rod end is reassembled, both sides of the housing must be staked down onto the flat shoulder of the rack.

Removing a ball socket assembly usually requires the use of two wrenches or a special tool. ● **SEE FIGURE 116–31**.

The flange around the outer tie rod must be restaked to the flat shoulder on the end of the rack, as shown in ● **FIGURE 116–32**.

Always follow the instructions that come with the replacement part(s). ● **SEE FIGURE 116–33**.

NOTE: When replacing a rack-and-pinion assembly, specify an entire replacement rack-and-pinion assembly if possible. A short rack does not include the bellows (boots) or inner tie rod ends (ball socket assemblies). The labor and cost required to exchange or replace these parts usually make it easier and less expensive to replace the entire steering unit.

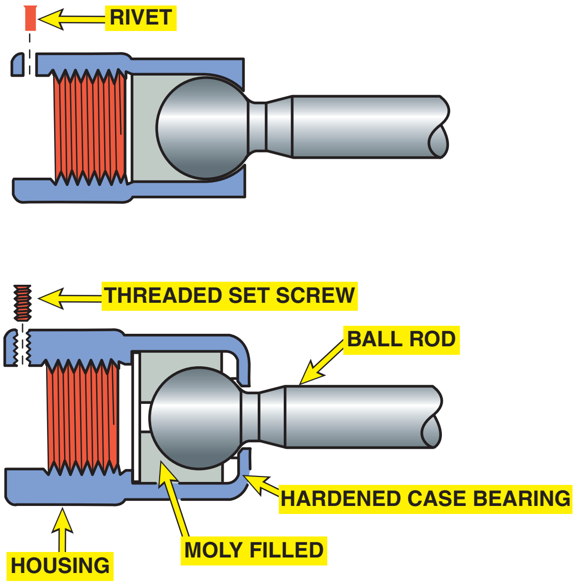


FIGURE 116–33 After replacing an inner tie rod end, the socket assembly should be secured with a rivet or set screw depending on the style of the replacement part.

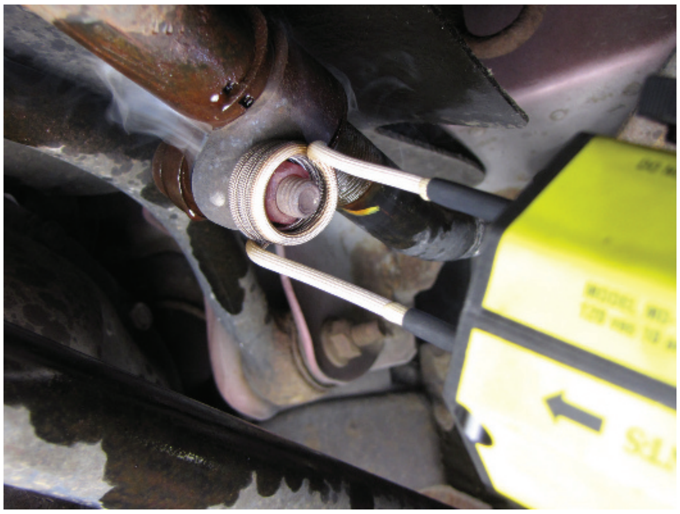

FIGURE 116–34 Using an inductive heater caused this retaining nut to be cherry red in a just a few seconds.

TECH TIP

Inductive Heating Tool

Fasteners are often rusted and difficult to remove especially those that are part of the steering system where they are exposed to road moisture, dirt, and debris. A heating tool, such as the Mini-Ductor, which uses electrical induction to heat a coil at the tip, is the tool that many experts recommend to use when heating of a fastener is needed. Using this tool allows a technician to heat a part quickly without the hazard of using an open flame. ● **SEE FIGURE 116–34**.

DRY PARK TEST

STEP BY STEP

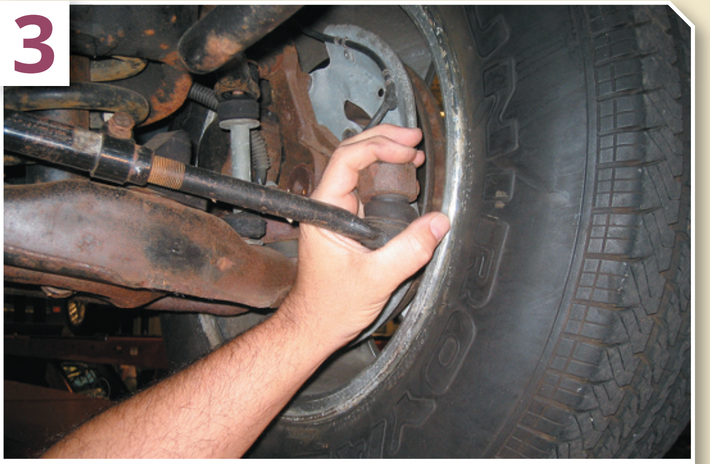
1

Drive the vehicle onto a drive-on-type hoist and have an assistant gently rotate the steering wheel back and forth about 2 inches (50 mm).

2

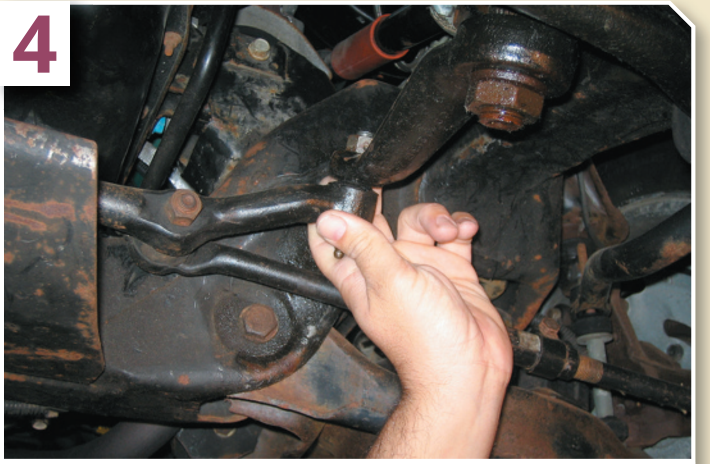
Perform a visual inspection of the steering and suspension system, looking for damage from road debris or other faults.

3



As the assistant wiggles the steering wheel, grasp the joint at the outer tie rod end on the driver's side to check for any movement.

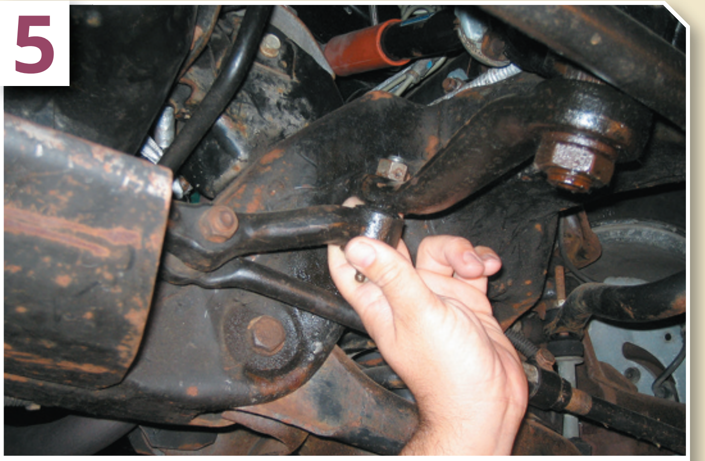
4



Next, check for any freeplay at the pitman arm.

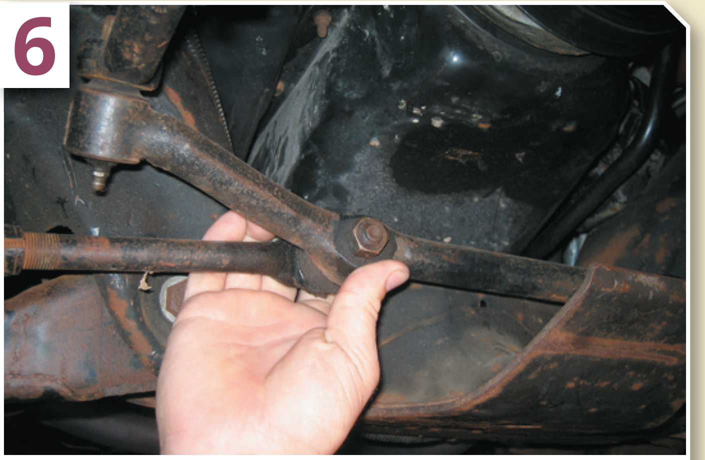
DRY PARK TEST

5



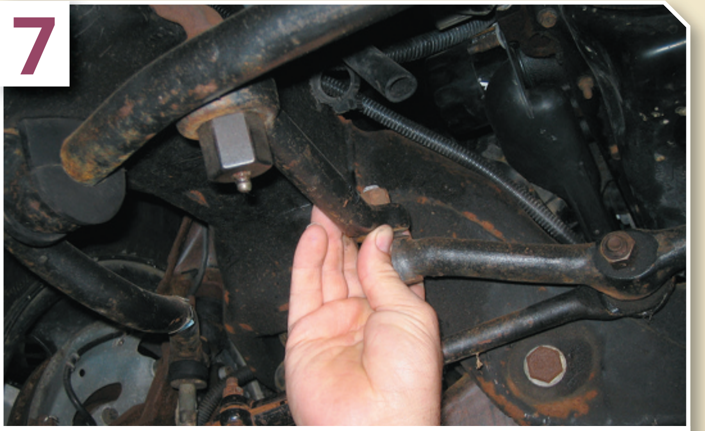
Check the joint between the left inner tie rod end and the center link for play.

6



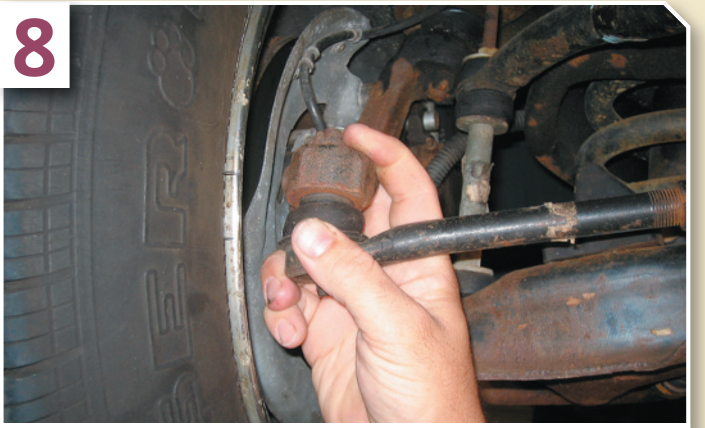
Move to the passenger side and check for any looseness at the joint between the center link and the right-side inner tie rod end.

7



Check for looseness at the idler arm connector to the center link and the idler arm at the frame mount.

8



Check for looseness at the passenger-side outer tie rod end. After the inspection, record the results on the work order.

HYDRAULIC POWER STEERING SYSTEMS

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Describe the operation of hydraulic power steering systems.
- Discuss the components and operation of power steering pumps.
- Explain the purpose and function of integral power steering.
- Discuss the purpose and function of variable effort steering systems.
- Discuss power steering diagnosis and troubleshooting.
- Describe service of power steering components and fluid.

KEY TERMS:

HYDRAULIC POWER STEERING SYSTEMS

PURPOSE AND FUNCTION Power-assisted steering hydraulically boosts the mechanical steering gear operation so the driver can turn the steering wheel with less effort for the same response. Hydraulic power steering has been available since the 1950s, and many late-model systems are enhanced by electronic controls.

FUNDAMENTALS Hydraulics is the study of liquids and their use to transmit force and motion. Hydraulic systems transmit force and motion through the use of fluid pressure. The terms used and their meaning include

- **Force—Force** is a push or pull acting on an object and is usually measured in pounds of force or Newtons.
- **Pressure—Pressure** is measured in force per unit of area, such as pounds per square inch (PSI), or kilopascals (kPa). One PSI is equal to 6.9 kPa.

PASCAL'S LAW The Pascal is a unit of measure named after the French scientist Blaise Pascal (1623–1662), who studied the behavior of fluids in closed systems. One of his discoveries, known as **Pascal's law**, states:

> When force is applied to a liquid confined in a container or an enclosure, the pressure is transmitted equally and undiminished in every direction.

Hydraulic systems can transmit force and motion through liquids because, for all practical purposes, a liquid cannot be compressed. No matter how much pressure is placed on a liquid, its volume remains the same. This allows a liquid to transmit force much like a mechanical lever. ● **SEE FIGURE 117–1**.

The advantage of a liquid over a mechanical lever is that a liquid has volume but does not have a fixed shape. Because it assumes the shape of its container, a liquid can transfer force through pipes and passages of any shape. A liquid can also decrease or increase the force it transmits depending on the area of the output surface to which the force is applied. ● **SEE FIGURE 117–2**.

POWER STEERING PUMP AND RESERVOIR

PARTS AND OPERATION The power steering pump draws fluid from the reservoir, pressurizes it, and delivers it to the power steering system. A power steering pump produces a high-pressure stream of fluid, typically in the 1,500 PSI

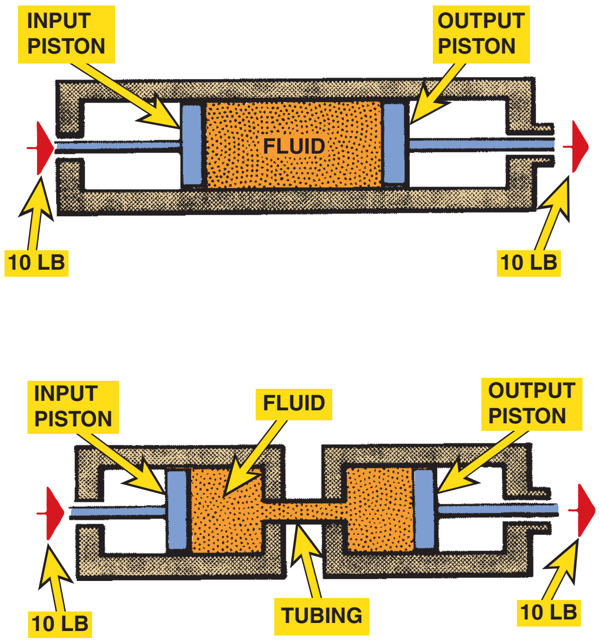

FIGURE 117–1 Hydraulic fluid transmits the same force whether it passes through a single chamber or two chambers connected by a narrow passage.

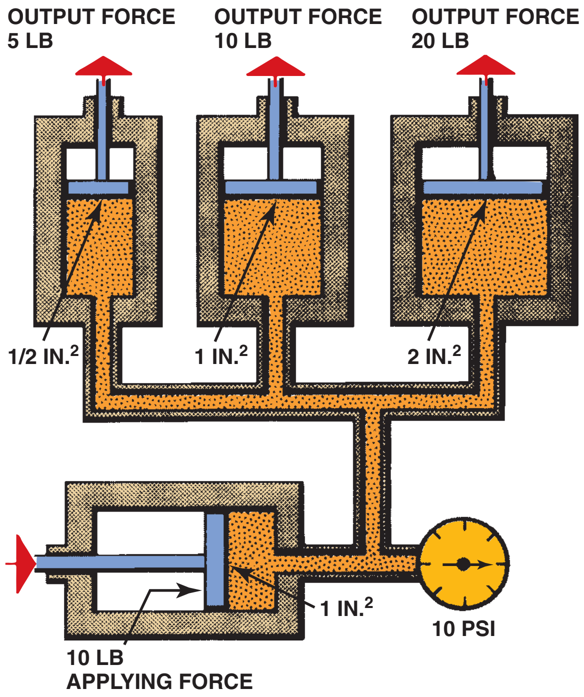

FIGURE 117–2 A fluid applies a force equal to the applied force on a surface that is equal in size to the applying surface. If the surface is half the size, then the fluid exerts half the force; if the surface is twice as large, the fluid exerts twice the force.

10,500 kPa) range. A reservoir stores power steering fluid. The fluid reservoir may be either integral to (built into) the pump or remotely mounted and connected to the pump by a hose. The power steering fluid reservoir is usually made of either plastic or stamped metal, and it includes the fluid filler neck, cap, and dipstick. An **integral reservoir** is part of the pump, and the pump itself operates submerged in power steering fluid. ● **SEE FIGURE 117–3**.

REMOTE RESERVOIRS

Although once common, steering pumps with an integral reservoir have given way to those with a remote reservoir on many current-production vehicles. This is because the remote reservoir allows for a smaller, more compact pump assembly that is better suited to the cramped engine compartment of a modern vehicle. A **remote reservoir** is a separate assembly from the pump and provides fluid to it through a suction hose. ● **SEE FIGURE 117–4**.

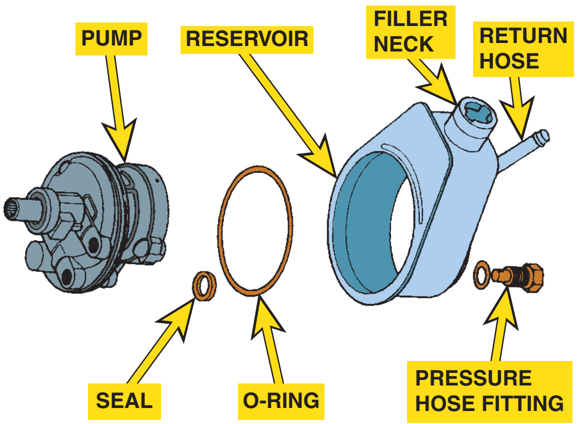

FIGURE 117–3 A typical integral power steering pump when the pump is mounted inside the reservoir.

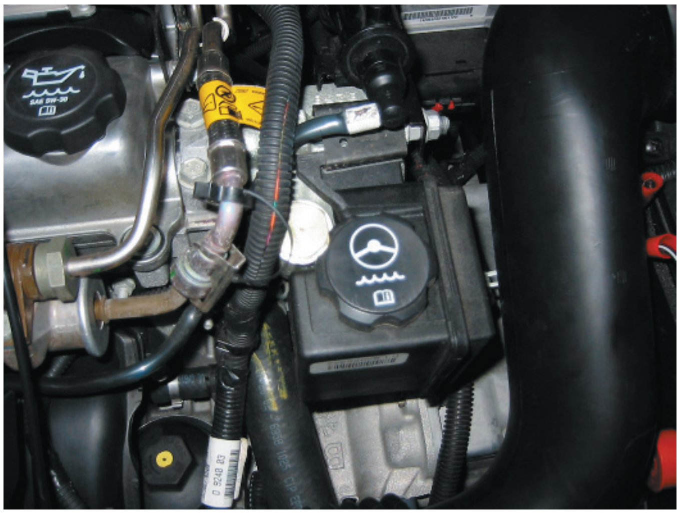

FIGURE 117–4 Typical remote reservoir.

FORCES AND PRESSURES INVOLVED

A typical power steering system requires only 2 to 3.5 pounds (0.9 to 1.6 kg) of driver effort to turn the steering wheel. Most power steering systems use an engine-driven hydraulic pump. Power steering hydraulic pumps are usually belt driven from the front crankshaft pulley of the engine. Pumps come in many sizes and styles. ● **SEE FIGURE 117–5**.

The power steering pump delivers a constant flow of hydraulic fluid to the power steering gear or rack. A typical power steering pump requires less than 1/2 horsepower, which is less than 1% of engine power while driving straight ahead. Even while parking at low speed, the power steering requires only about 3 horsepower while providing high hydraulic pressures. Typical pressures generated by a power steering system include the following:

- *Straight ahead* less than 150 PSI (1,400 kPa)
- *Cornering* about 450 PSI (3,100 kPa)
- *Parking* (maximum) 750–1,400 PSI (5,200–10,000 kPa)

TYPES OF PUMPS

The power steering pump drive pulley is usually fitted to a chrome-plated shaft with a press fit. The shaft

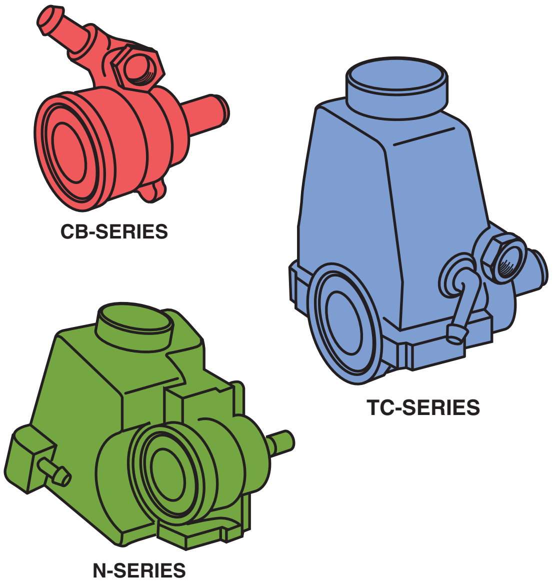

FIGURE 117–5 Typical power steering pump assemblies.

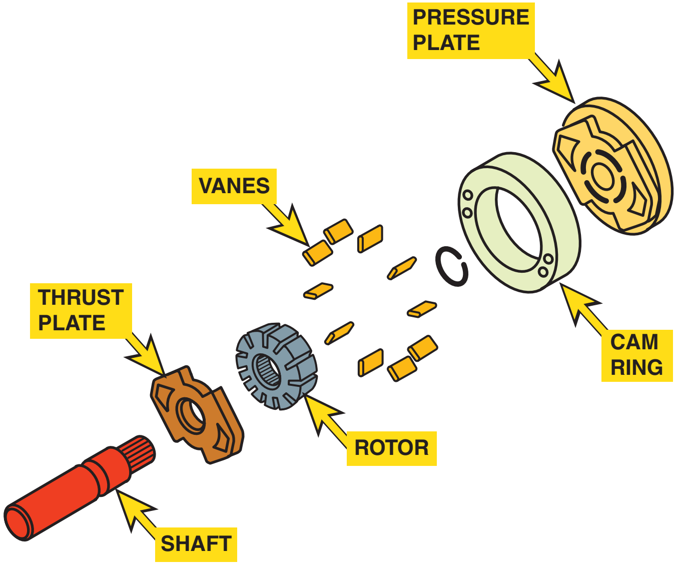

FIGURE 117–6 General Motors vane-type pump.

is applied to a rotor with vanes that rotate between a thrust plate and a pressure plate. ● **SEE FIGURE 117–6**.

- When the engine starts, the drive belt rotates the power steering pump pulley and the rotor assembly inside the power steering pump.
- Centrifugal force and hydraulic pressure push the vanes of the rotor outward into contact with the pump ring.
- The shape of the pump ring causes a change in the volume of fluid between the vanes. As the volume increases, the pressure is decreased in the space between the vanes and draws in fluid from the pump reservoir. When the volume between the vanes decreases, the pressure is increased and flows out the pump discharge port. ● **SEE FIGURES 117–7, 117–8, AND 117–9**.

CONTROL VALVE The pressure outlet hose connects to a fitting that threads into the outlet port of the pump body. A modulator valve, commonly called a **flow control valve**, installs in the same bore as the hose fitting. ● **SEE FIGURE 117–10**.

The modulator valve is a spring-loaded pressure-relief device that bleeds off excess pressure to prevent system damage.

- When pump output is more than what the power steering system requires, the excess pressure overcomes spring force and moves the valve down in its bore.
- This uncovers an orifice through which the fluid can flow back into the inlet passages. An orifice is a small opening that regulates fluid pressure and flow. It can be a restriction in a fluid line or a hole between two fluid chambers. The opening is called a *variable orifice* because the size of the opening varies with the amount of pressure applied to the valve.
- When fluid pressure is not high, spring force keeps the valve seated so that all of the pressurized fluid flows through the outlet port and into the pressure hose. Because the engine drives the pump, the power steering pump places a load on the engine whenever the engine is running.

The pressure increases when the steering wheel is turned to its full stop in either direction. To handle the excess pressure, a

FIGURE 117–7 Vane pump operation. In phase 1, the rotor moves past the opposed suction ports, and the vanes move out to maintain contact with the ring. This creates a low-pressure area, drawing fluid into the cavities formed by the vanes. As the rotor continues to move during phase 2, the vanes follow the contour of the ring. The contour of the ring forms a larger cavity between the vanes. This increases the suction and draws more fluid into the pump.

pressure-relief passage runs from a point near the pressure hose fitting to the spring end of the modulator valve. Inside the passage is a **pressure-relief valve**. The spring end of the modulator valve forms a seat for the pressure relief check ball. Under normal circumstances, the check ball remains seated.

FREQUENTLY ASKED QUESTION

What Is the Purpose of the PSP Switch in the High-Pressure Line?

Under certain conditions, such as when the steering wheel is turned to or near full stop for more than a few seconds, pressure builds in the system and the pump must work harder to keep up with the demand. As a result, the pump draws more power from the engine. If the engine is running at idle, the extra load can cause it to stall. A pressure switch, known as the **power steering pressure (PSP)** switch, transmits an electronic signal to the powertrain control module (PCM) when the pressure in the system is high enough to increase the load on the engine. In response to the PSP switch signal, the PCM increases the engine idle speed to prevent stalling.

2. CHECK BALL LIFTS OFF ITS SEAT
1. FLUID FLOWS TO RELIEF CHECK BALL

FIGURE 117–11 The pressure-relief check ball unseats, allowing fluid to flow back into the pump inlet if the pressure rises above a certain limit.

The parts of the pressure-relief valve include

- Spring
- Valve piston
- Check ball
- Seat

A shim installs on the check ball seat to adjust the pressure at which the check ball unseats to open the pressure-relief valve. Normally, the spring force holds the piston against the check ball to keep it in its seat. When pressure becomes excessive in the pressure-relief passage, the check ball raises off its seat to allow fluid to flow through the relief passage and out through an orifice in the modulator valve. ● **SEE FIGURE 117–11**.

The pressure when this occurs varies from 750 to 1,400 PSI (5,200 to 10,000 kPa) depending on the calibration of the pressure-relief valve. When power steering systems are pushed to the limit, most will make a chattering or squealing noise until the pressure is reduced.

POWER STEERING HOSES Because the power steering pump and the steering gear are not part of the same assembly, the system requires two hoses to connect the power steering pump and gear assembly.

- The pressure hose is connected to the flow control/relief valve. This hose supplies pressurized fluid to the steering gear.
- The second hose is called the *return hose* and it returns the fluid from the steering gear back to the pump.
- Some vehicles will use a cooler in the return path to the pump. The cooler is used to reduce the temperature of the fluid before it enters the pump. The cooler is often a length of metal line that is routed in the air stream under the vehicle so that air flowing past it will cool the fluid inside the line. ● **SEE FIGURE 117–12**.

INTEGRAL POWER STEERING

PURPOSE AND FUNCTION In an integral power steering system, the control valve and a power piston which applies force to the pitman arm are incorporated into the steering gear construction. The control valve regulates the application of pressurized fluid against the power piston, and the power piston helps move the pitman arm when pressure is applied to one side of it.

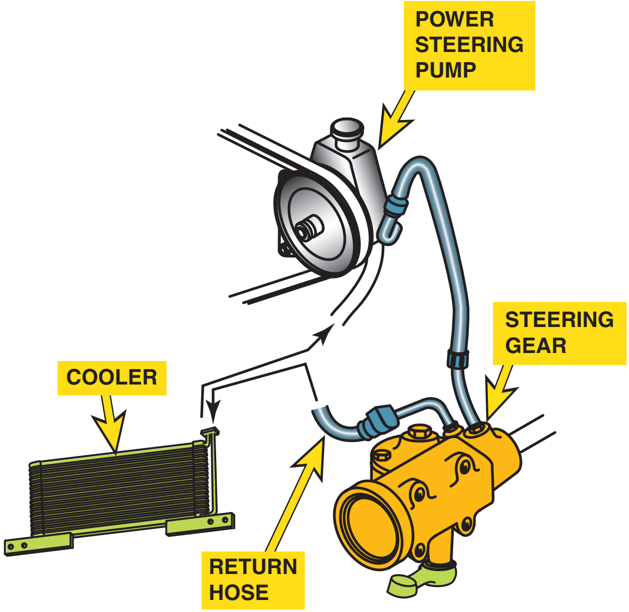

FIGURE 117–12 The power steering fluid cooler, if used, is located in the return hose. Often the "cooler" is simply a length of return metal line that is arranged in a loop and routed near the front of the vehicle. The airflow past the return line helps reduce the temperature of the fluid.

INTEGRAL STANDARD STEERING GEAR Most standard steering gears with power assist are the recirculating-ball type, and the ball nut functions as the power piston. The steering gear is lubricated from the power steering fluid that is flowing through the unit. Hydraulic pressure from the steering gear control valve is applied directly against the ball nut to help move it through the housing. The ball nut in this type of power steering gear is called the power piston because hydraulic pressure moves it as if it were a piston traveling in a cylinder. ● **SEE FIGURE 117–13**.

ROTARY CONTROL VALVE A **rotary control valve** is a two-piece assembly that operates by rotating an inner valve within an outer valve. A steering gear with a rotary control valve is also a torsion bar steering gear, because a small torsion bar is used to control valve movement. The rotary control valve consists of two cylindrical elements:

1. Inner valve element
2. Outer valve element

The inner valve element is secured to the steering gear input shaft and the torsion bar. In the valve, the inner element and the input shaft are one piece, and the torsion bar attaches between them connecting the inner valve element and the input shaft. ● **SEE FIGURE 117–14**.

The inner element assembly fits inside the outer valve element, and is also secured to the torsion bar by a pin. The outer valve element is also the steering worm gear.

- The torsion bar acts as a spring between the two elements to allow movement between them when the steering shaft turns. The spring force of the torsion bar tends to pull the elements back to their neutral positions when the steering wheel is released or returned to center. The strength of the torsion bar determines steering feel.

FIGURE 117–15 When the steering wheel is in the straight-ahead position, all of the ports in a rotary valve are open equally to the pressure and return circuits.

- A weak torsion bar moves easily and provides soft steering, while a strong bar resists movement and makes steering feel firm. Many high-performance vehicles use a steering gear that has a thicker torsion bar to increase the firmness of the steering.

The surfaces of the inner and outer elements have grooves machined into them through which fluid can flow. Passages carry fluid from some of the inner-element grooves to the center of the element where it travels through the return line to the pump reservoir. The outer element has three sets of fluid passages that connect the outside of the element to a groove at the inside. One set of passages carries fluid into the element from the pressure hose fitting, the second set carries fluid to and from the left-turn side of the power piston, and the third carries it to and from the right-turn side. When the steering wheel is aimed straight ahead, the valve is in its neutral position. Fluid enters the valve and flows equally to both sides of the steering gear piston and to the return line. ● **SEE FIGURE 117–15.**

When the steering wheel and steering shaft turn to the left, the inner element twists on the torsion bar and repositions the valve ports. In this left-turn position, pressurized fluid flowing into the valve can only exit through the left-turn ports. ● **SEE FIGURE 117–16.**

Meanwhile, the right-turn ports align with the return ports to bleed off residual pressure from the opposite side of the power piston. Pressurized fluid flowing through the left-turn ports is directed into the steering gear, where it applies force to the power piston and reduces the effort needed to turn the steering linkage to the left. ● **SEE FIGURE 117–17.**

FIGURE 117–16 During a left turn, the inner element turns so that the left-turn circuits are open to pressure and the right-turn circuits are open to the return circuit.

As the piston moves, it forces fluid out of the right-turn side, and that fluid returns through the control valve to the pump reservoir. Exactly the opposite flow occurs during a right-hand turn: The right-turn ports are opened and the left-turn ports exhaust to the return line. ● **SEE FIGURE 117–18**.

Hydraulic pressure moves the piston up the housing bore during a right-hand turn. ● **SEE FIGURE 117–19**.

When the steering wheel is released, the spring force of the torsion bar returns the two elements to their natural positions. Fluid pressure equalizes throughout the steering gear and re-centers the piston in the middle of the steering gear.

POWER RACK-AND-PINION STEERING The rotary control valve on a power rack-and-pinion steering gear is located between the steering gear input shaft and the pinion gear. ● **SEE FIGURE 117–20**.

Fluid discharged by the valve travels through external steel lines to either side of the power piston located in the rack housing. A steel air-transfer tube allows air displacement between the boots as they compress and expand, since the power piston prevents air from passing through the rack housing. The rotary valve in a rack-and-pinion steering unit operates in the same manner as the one previously described for a standard steering gear. During a left-hand turn, the control valve directs fluid flow into the left-turn steel line, which routes it to the right-hand side of the power piston in order to move the rack to the left. As this happens, fluid on the opposite side of the power piston is forced out through the right-turn steel line and back to the control valve, where it is exhausted to the return circuit. When the steering wheel is turned to the right, fluid flow is reversed so the power piston moves to the right and fluid in

FLOW CONTROL VALVE OPERATION The operation of the flow control valve includes the following stages:

- When the power steering pump begins operation, the fluid from the output of the pump flows into the control valve.
- The fluid then flows through the orifice, where a pressure differential is formed. The pressure differential results in a higher pressure on the pump side than on the system side. The fluid from the orifice flows into the power steering system and through a passage on the backside of the control valve. ● **SEE FIGURE 117–22**.
- The fluid on the backside of the control valve is used to assist the spring force acting on the valve.
- At this point, the combination of the spring force and hydraulic pressure is higher than the output pressure of the pump. This causes the control valve to block the passage to the pump intake. When the output pressure is higher than the spring force, the pressure behind the valve

forces the control valve to move. The movement of the valve opens the passage to the intake side of the pump. This allows some of the fluid to flow into the passage.

- As the pump speed continues to increase, the valve moves more to compensate for the higher pressure and flow. The pressure and flow in the power steering system must remain in the correct range or the steering system components can be damaged. Failure of the control valve to regulate the pressure in the power steering system can result in excessive pressure and temperature. As long as fluid can flow through the system, the control valve can regulate the pressure. ● **SEE FIGURE 117–23**.

However, there are times during normal operation when the flow in the system will stop. Fluid flow can stop during parking maneuvers and when the steering wheel is turned to the extreme right and left positions. When the fluid flow through the system stops, the pressure equalizes on both sides of the orifice. This creates equal pressure on both sides of the control valve. Because the backside of the valve has a spring, the combination of the hydraulic pressure and spring force positions the control valve to prevent flow into the pump intake passage. As the pump continues to operate, the pressure in the system builds. If the pressure is not relieved, the system can be damaged. To prevent this, the control valve has a check valve inside it. At a specific pressure, the check valve opens to relieve the pressure on the backside of the control valve. This creates a pressure differential and allows the control valve to move. With the control valve moved, the high pressure is allowed into the pump intake passage. ● **SEE FIGURE 117–24**.

VARIABLE-EFFORT STEERING

PURPOSE AND FUNCTION Variable-effort steering (VES) systems are designed to provide variable power-assisted steering. The amount of power assist

- Increases at lower vehicle speeds to aid parking maneuvers.
- Decreases at higher speeds for greater road feel.

As examples, General Motors uses four different VES systems including

- Electronic Variable Orifice (EVO)
- Two-Flow Electronic (TFE)
- Speed Sensitive Steering (SSS)
- Magnasteer®

ELECTRONIC VARIABLE ORIFICE (EVO) SYSTEM The main components of the EVO system include

- Vehicle speed sensor
- Power steering control module (PSCM)
- Steering wheel speed sensor
- Power steering gear
- Power steering pump and solenoid actuator

FIGURE 117–25 (a) A typical rack and pinion steering gear assembly showing the location of the control valve, power piston, and inner rack seal. (b) EVO actuator assembly.

The actuator is a solenoid-operated pintle valve. Electrical current flowing through the solenoid controls the position of the pintle in relation to the orifice. ● **SEE FIGURE 117–25**.

- As the vehicle speed increases, the control module provides a higher current flow and the solenoid positions the pintle to change the size of the orifice. This increased speed results in a reduced amount of hydraulic flow and provides less hydraulic pressure to the steering gear.
- The control module uses the signal from the vehicle speed sensor to calculate the required amperage for the solenoid. The amperage has a direct effect on steering effort and the flow rate to the gear. As the vehicle speed increases, the solenoid extends the pintle and reduces the size of the orifice. Hydraulic pressure is being reduced as the vehicle speed increases and less power assist is available.
- The other sensor for the EVO system is the steering wheel speed sensor. This sensor is used to determine if the vehicle operator is performing an evasive steering maneuver.
- In this situation, the controller increases the hydraulic pressure to assist the operator. The faster the driver turns the steering wheel, the stronger the signal generated by the sensor. The faster the steering wheel is rotated, the more the solenoid retracts the pintle and enlarges the size of the orifice. This increases hydraulic pressure to the steering gear and provides more power assist for the operator.

TWO-FLOW ELECTRONIC (TFE) SYSTEM The main components of the TFE system include

- Power steering pump and solenoid actuator
- Steering rack-and-pinion gear
- Control module
- Powertrain control module (PCM)

The TFE actuator is a solenoid-operated pintle valve. The pintle valve has only two positions:

1. Maximum assist
2. Reduced assist

When the solenoid is provided a ground from the control module, the pintle extends out from the orifice and provides maximum assist. When the control module opens the ground path, the pintle moves in to restrict the orifice and thus reduces steering assist. The PCM provides the control module with a vehicle speed signal. The logic circuits in the control module determine when to energize the solenoid.

- The solenoid is energized whenever the vehicle speed is approximately 20 MPH (32 km/h) or lower and the pintle is extended, causing the power steering pressure to increase. This provides maximum assist and the steering effort is low.
- When the vehicle speed is higher than 20 MPH (32 km/h), the pintle is moved in and the steering pressure is low. This provides reduced assist and higher steering effort.

SPEED SENSITIVE STEERING (SSS) SYSTEM The major components of the SSS system include

- Power steering pump
- SSS actuator
- Steering gear
- Road sensing suspension (RSS) control module

The actuator is a solenoid-operated valve that controls the flow of fluid into the chambers of the steering gear valve. As more fluid flows into the chamber, pressure is built against the four pistons that are located around the spool shaft. As the pistons are loaded and pushed against the spool shaft, steering effort is increased. Unlike the EVO and TFE systems, the SSS system uses hydraulic pressure to resist movement in the steering gear. The amount of fluid allowed into the chambers is based on the electrical current flow through the solenoid. The road sensing suspension control module, using the signal from the vehicle speed sensor, calculates the required amperage for the solenoid.

- The amperage has a direct effect on steering effort and the hydraulic flow rate into the chambers of the spool shaft.
- As the vehicle's speed increases, the steering effort is increased. The steering effort adjustment begins at a vehicle speed of 20 MPH (32 km/h).

MAGNASTEER® Another type of variable effort power steering system used by General Motors is the Magnasteer® system. This system uses a variable bidirectional magnetic rotary actuator built into the steering rack. The bidirectional magnetic rotary actuator has no effect on the hydraulic operation of the steering rack. The main components in the system include

- Power steering pump
- Magnasteer® actuator assembly
- Steering gear
- Electronic brake control module (EBCM)

The Magnasteer® system uses a conventional rack-and-pinion steering gear and an engine-driven hydraulic pump to provide power assist. The Magnasteer® actuator consists of the following:

- A permanent magnet attached to the rotary input shaft
- A pole-piece assembly attached to the pinion
- An electromagnetic coil mounted in the steering gear housing

Integrated with the pinion shaft is a spool valve that senses the level of torque in the shaft and applies hydraulic pressure to the steering rack whenever assistance is needed.

The electromagnet acts in parallel with the input shaft from the steering wheel to open or close the spool valve. The electromagnet generates variable torque, which can either increase or decrease the amount of steering torque that is needed to open the spool valve. ● **SEE FIGURES 117–26 AND 117–27**.

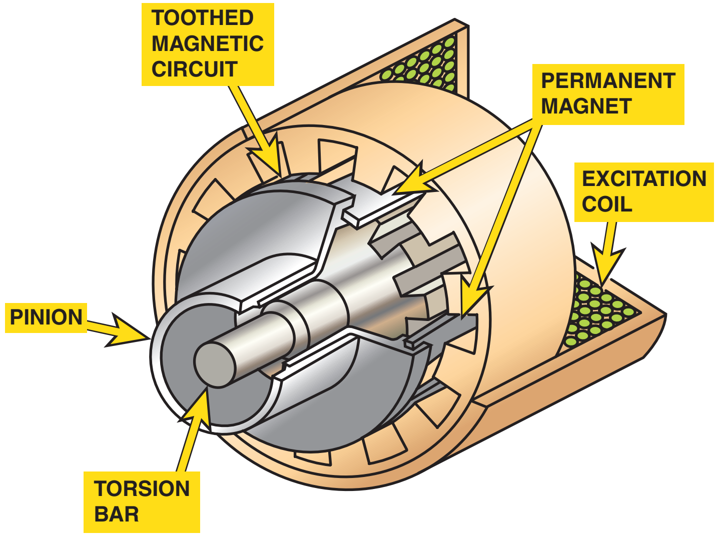

FIGURE 117–26 Integrated with the pinion shaft is a spool valve that senses the level of torque in the shaft and applies hydraulic pressure to the steering rack whenever assistance is needed. The electromagnet acts in parallel with the input shaft from the steering wheel to open or close the spool valve. The electromagnet generates variable torque, which can either increase or decrease the amount of steering torque that is needed to open the spool valve.

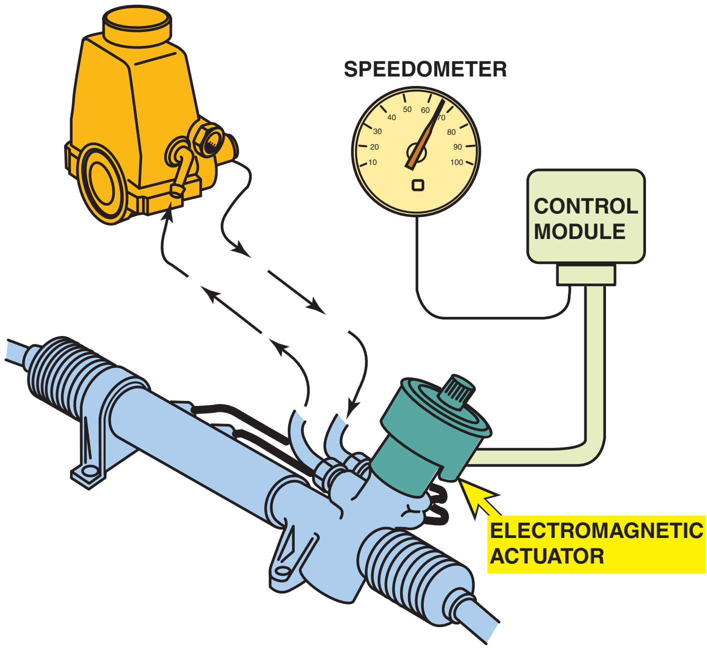

FIGURE 117–27 Magnasteer® system.

To vary the amount of steering assist, the EBCM uses the signal from the wheel speed sensor to calculate the required amperage and direction of current flow to the Magnasteer® actuator.

The amperage and direction of current flow have a direct effect on steering effort and the flow rate to the rack piston.

- When the vehicle is stationary, approximately 1.6 amperes of current is flowing through the electromagnetic coil.
- As the vehicle speed increases to approximately 45 MPH, the current decreases to 0 amps. The EBCM then switches the direction of current flow. Current flow through the electromagnetic coil causes either a magnetic attraction or repelling in the Magnasteer® actuator.

- At low vehicle speeds below 45 MPH, the direction of current flow creates a magnetic field that opposes the permanent magnet. The repelling force of the magnetic field assists the spool valve in moving out of alignment with the valve body, and this increases the power assist. With vehicle speeds below 45 MPH, increased current provides increased steering assist.
- At vehicle speeds above 45 MPH, the direction of current through the electromagnetic coil creates a magnetic field that attracts the permanent magnet. The magnet helps keep the spool valve aligned with the valve body, and this reduces the power assist and provides a greater road feel. As the vehicle speed increases, the amount of effort required to overcome the attracting force of the magnetic field increases. With vehicle speeds above 45 MPH, increased current flow provides decreased steering assist.

POWER STEERING DIAGNOSIS

ITEMS TO CHECK Power steering systems are generally very reliable, yet many problems, such as hard steering, are caused by not correcting simple service items such as the following:

1. A loose, worn, or defective power steering pump drive belt. This can cause jerky steering and belt noise, especially when turning. It is generally recommended that all belts, including the serpentine (poly V) belt, be replaced every four years. If the vehicle does not use a belt tensioner, then a belt tension gauge is needed to achieve the specified belt tension. Install the belt and operate the engine with all of the accessories turned on to "run-in" the belt for at least five minutes. Adjust the tension of the accessory drive belt to factory specifications or use the following table for an example of the proper tension based on the size of the belt. ● **SEE CHART 117–1**.

   Replace any serpentine belt if more than three cracks appear in any one rib within a 3 inch span.

NOTE: Do not guess at the proper belt tension. Always use a belt tension gauge or observe the marks on the tensioner. ● **SEE FIGURE 117–28**.

2. A bent or misaligned drive pulley is usually caused by an accident or improper reassembly of the power steering pump after an engine repair procedure. This can cause a severe grinding noise whenever the engine is running and may sound like an engine problem.

SERPENTINE BELTS	
NUMBER OF RIBS USED	TENSION RANGE (LB)
3	45–60
4	60–80
5	75–100
6	90–125
7	105–145

CHART 117–1

Belt tension is related to the number of ribs and usually falls within the range shown. Always check service information for the exact belt tension for the vehicle being serviced.

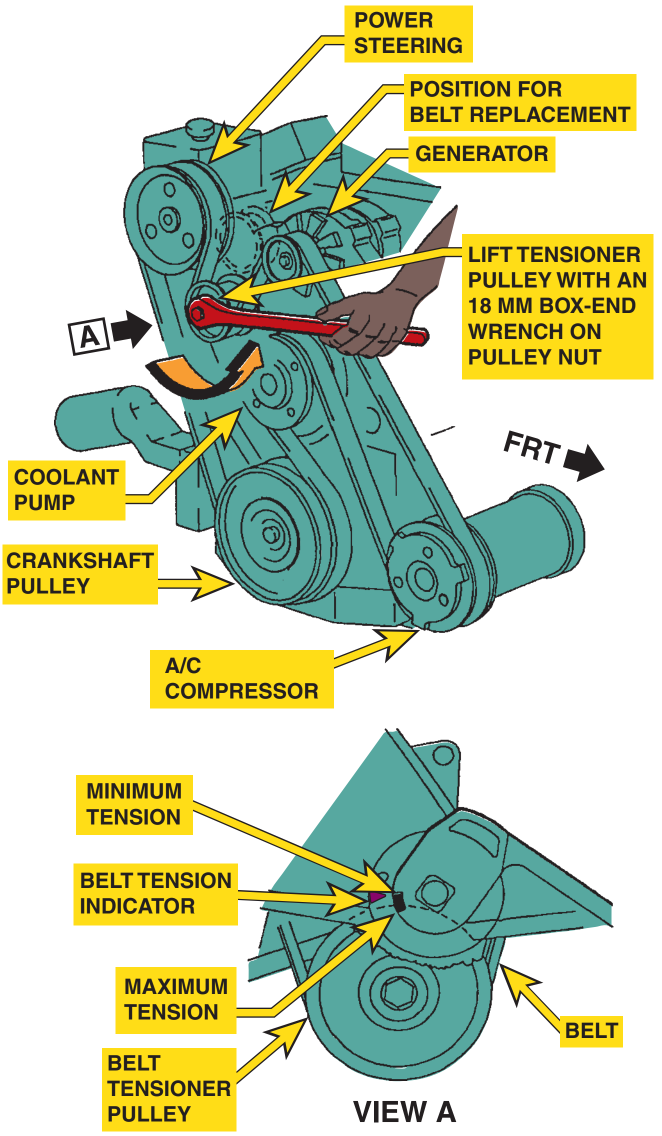

FIGURE 117–28 A typical service manual illustration showing the belt tensioner indicator marks.

3. Low or contaminated power steering fluid is usually caused by a slight leak at the high-pressure hose or defective inner rack seals on a power rack-and-pinion power steering system. This can cause a loud whine and a lack of normal power steering assist. See the Tech Tip, "The Visual Test."
4. Broken or loose power steering pump mounting brackets. In extreme cases, the pump mounting bolts can be broken. These problems can cause jerky steering. It is important to inspect the pump mounting brackets and hardware carefully when diagnosing a steering-related problem. The brackets tend to crack at the adjustment points and pivot areas. Tighten all the hardware to ensure the belt will remain tight and not slip, which would cause noise or a power-assist problem.
5. Underinflated tires.
6. Engine idle speed below specifications.
7. A defective power steering pressure switch, if equipped. If this switch fails, the computer will not increase engine idle speed while turning.
8. Internal steering gear mechanical binding.

As part of a complete steering system inspection and diagnosis, a steering wheel turning effort test should be performed. The power steering force, as measured by a spring scale during turning, should be less than 5 pounds (2.3 kg).

CAUTION: Some vehicles use power steering reservoir caps with left-hand threads. Always clean the top of the cap and observe all directions and cautions.

POWER STEERING FLUID

PURPOSE AND FUNCTION The correct power steering (PS) fluid is *critical* to the operation and service life of the power steering system. The exact power steering fluid can be found in the following places:

- On the cap of the power steering reservoir
- In the owner's manual
- In service information

TECH TIP

The Visual Test

Whenever diagnosing any power steering complaint, check the level *and* condition of the power steering fluid. Often this is best accomplished by putting your finger down into the power steering fluid reservoir and pulling it out to observe the texture and color of the fluid. ● **SEE FIGURE 117–29**.

A common problem with some power rack-and-pinion units is the wearing of grooves in the housing by the Teflon sealing rings of the spool (control) valve. When this wear occurs, aluminum particles become suspended in the power steering fluid, giving it a grayish color and thickening the fluid. Normally, clear power steering fluid that is found to be grayish in color and steering that is difficult when cold are clear indications as to what has occurred and why the steering is not functioning correctly.

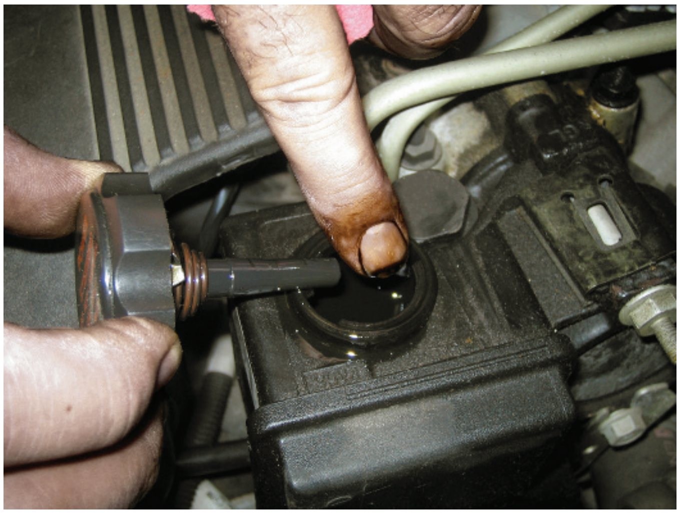

FIGURE 117–29 A check of the power steering fluid should include inspecting not only the level but the condition and color of the fluid, which could indicate a possible problem with other components in the steering system.

POWER STEERING CHECKS Power steering checks include the following inspections:

1. Check the power steering fluid level. Bleed the air from the system by turning the steering wheel lock-to-lock with the engine at idle speed.
2. Check the condition and tension of the drive belt. If in doubt, replace the belt.
3. Inspect the condition of all hoses, checking for any soft hose or places where the hose could touch another component.
4. Check the tightness of all mounting bolts of the pump and gear.

POWER STEERING FLUID FLUSHING PROCEDURE Whenever there is any power steering service performed, such as replacement of a defective pump or steering gear or rack-and-pinion unit, the entire system should be flushed. If all of the old fluid is not flushed from the system, small pieces of a failed bearing or rotor could be circulated through the system. These metal particles can block paths in the control valve and cause failure of the new power steering pump or gear assembly.

Besides flushing the old power steering fluid from the system and replacing it with new fluid, many technical experts recommend installing a filter in the low-pressure return line as an added precaution against serious damage from debris in the system. Power steering filters are commonly available through vehicle dealer parts departments, as well as aftermarket sources from local auto supply stores. Always follow the vehicle manufacturer's recommended flushing procedure. Two people are needed to flush the system. Use the following steps:

STEP 1 Raise the front wheels off the ground.

STEP 2 Remove the low-pressure return hose from the pump and plug the line fitting on the pump.

STEP 3 Place the low-pressure return hose into an empty container.

STEP 4 Fill the pump reservoir with fresh fluid and start the engine.

STEP 5 As the old and dirty power steering fluid is being pumped into the container, keep the reservoir full of clean fluid while the assistant turns the steering wheel full lock one way to full lock the other way.

CAUTION: Never allow the pump reservoir to run dry of power steering fluid. Severe internal pump damage can result.

STEP 6 When the fluid runs clean, stop the engine and reattach the low-pressure return hose to the pump reservoir.

STEP 7 Restart the engine and fill the reservoir to the full mark. Turn the steering wheel back and forth, avoiding the stops one or two times to bleed any trapped air in the system.

BLEEDING AIR OUT OF THE SYSTEM If the power steering fluid is tan, there may be air bubbles trapped in the fluid. Stop the engine and allow the air to burp out to the surface for several minutes. Lift the vehicle off the ground, then rotate the steering wheel. This method prevents the breakup of large air bubbles into thousands of smaller bubbles that are more difficult to bleed out of the system.

NOTE: To help rid the power steering system of unwanted trapped air, it is recommended that the engine be cranked and that the wheels be turned from stop to stop with the tires off the ground. Check service information for the specified procedure to follow to disable ignition or fuel-injection system to keep the engine from starting. Do not crank the engine for longer than 15 seconds to prevent starter damage due to overheating. Allow the starter to cool at least 30 seconds before cranking again.

Sometimes trapped air just cannot be bled out of the system using ordinary methods. This trapped air makes the pump extremely noisy and this noise sometimes convinces the technician that the pump itself is defective. If the power steering system has been opened for repairs and the system has been drained, trapped air may be the cause.

TECH TIP

Multiple-Purpose Power Steering Fluid

Multiple-purpose power steering fluid does not mean *all*-purpose power steering fluid. Always check the power steering reservoir cap, service information, or owner's manual for the exact fluid to be used in the vehicle being serviced. The main reason for using the specified power steering fluid is the compatibility of the fluid with the materials used in seals and hoses of the system. Using the wrong fluid (substituting ATF, for example) can lead to seal or hose deterioration and/or failure and fluid leaks. Always use the power steering fluid recommended by the manufacturer. The correct fluid to use is often imprinted on or near the power steering reservoir fill cap or is found in the owner's manual or service information. ● **SEE FIGURE 117–30**.

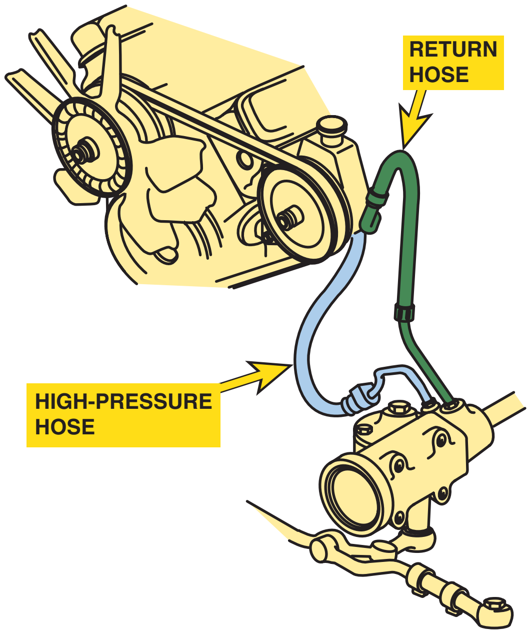

FIGURE 117–31 Inspect both high-pressure and return power steering hoses. Make sure the hoses are routed correctly and not touching sections of the body to prevent power steering noise from being transferred to the passenger compartment.

HOSE INSPECTION Both high-pressure supply and low-pressure return hoses should be inspected as part of any thorough vehicle inspection. While the low-pressure return hose generally feels softer than the high-pressure return hose, neither should feel *spongy*. A soft, spongy hose should always be replaced. ● **SEE FIGURE 117–31**.

When replacing any power steering hose, make certain that it is routed the same as the original and does not interfere with any accessory drive belt, pulley, or other movable component such as the intermediate steering shaft.

PRESSURE TESTING Use of a power steering pressure tester involves the following steps:

STEP 1 Disconnect the pressure hose at the pump.

STEP 2 Connect the hoses of the tester to the pump and the disconnected pressure line. ● **SEE FIGURE 117–32**.

STEP 3 Open the valve on the tester.

STEP 4 Start the engine. Allow the power steering system to reach operating temperatures.

STEP 5 The pressure gauge should register 80 to 125 PSI (550 to 860 kPa). If the pressure is greater than 150 PSI (1,400 kPa), check for restrictions in the system, including the operation of the poppet valve located in the inlet of the steering gear.

STEP 6 Fully close the valve three times. (Do not leave the valve closed for more than five seconds!) All three readings should be within 50 PSI (345 kPa) of each other and the peak pressure should be higher than 1,000 PSI (6,900 kPa).

STEP 7 If the pressure readings are high enough *and* within 50 PSI (345 kPa) of each other, the pump is operating normally.

STEP 8 If the pressure readings are high enough, yet not within 50 PSI (345 kPa) of each other, the flow control valve is sticking.

STEP 9 If the pressure readings are less than 1,000 PSI (6,900 kPa), replace the flow control valve and recheck. If the

CASE STUDY

The Noisy Power Steering Pump

A customer complained that the power steering on their Dodge Grand Caravan minivan had a very loud whining/growling/squealing noise for about 3–10 seconds on cold mornings at start-up. The owner had received a quote for several hundred dollars to replace the power steering pump, but then asked another shop for a second opinion. The second shop had experience with this issue and recommended replacing the power steering filter located in the bottom of the power steering pump reservoir. The owner agreed to have the filter and the fluid replaced for an amount far less than the previous quote. After replacing the filter and flushing the power steering fluid, the power steering was quiet and operated like new.

Summary:

Complaint—Power steering was noisy especially when cold.
Cause—The screen in the bottom of the reservoir plugs up and starves the pump of oil causing the noise.
Correction—The filter was replaced and the fluid flushed.

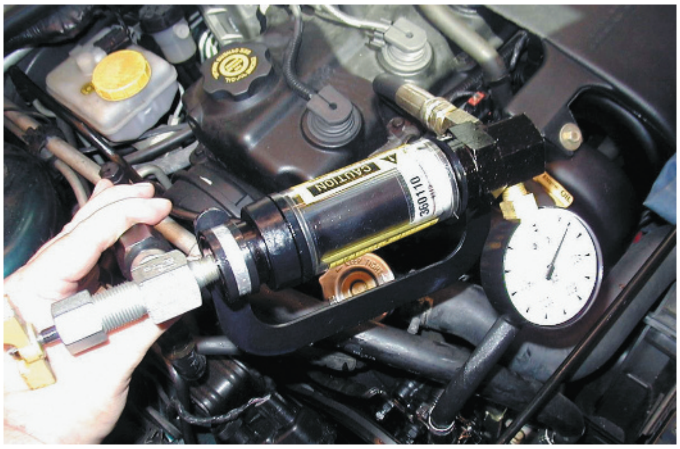

FIGURE 117–33 A power steering analyzer that measures both pressure and volume. The shut-off valve is used to test the maximum pressure of the pump.

pressures are still low, replace the rotor and vanes in the power steering pump or the entire pump assembly.

STEP 10 If the pump is working as designed, turn the steering wheel to both stops. If the pressure at both stops is not the same as the maximum pressure, the steering gear (or rack and pinion) is leaking internally and should be repaired or replaced. Many vehicle manufacturers recommend using a power steering analyzer that measures both pressure and volume, as shown in ● **FIGURE 117–33**.

Knowing the volume flow in the system provides information to the technician in addition to that of the pressure gauge. Many manufacturer's diagnostic procedures specify volume measurements and test results that can help pinpoint flow control or steering gear problems. Always follow the vehicle manufacturer's recommended testing procedures. ● **SEE CHART 117–2** for pressure and volume measurements specified by the manufacturer.

PUMP SERVICE Some power steering pump service can usually be performed without removing the pump, including the following:

1. Replacing the high-pressure and return hoses
2. Removing and cleaning the flow control valve assembly ● **SEE FIGURE 117–34**.

TYPICAL POWER STEERING PRESSURES AND VOLUME SPECIFICATIONS

STEERING ACTION	PRESSURE, PSI (kPa)	VOLUME* (Gal/min) (L./min)
Straight ahead, no steering	Less than 150 PSI (1,000 kPa)	2.0–3.3 gpm (10–15 lpm)
Slow cornering	300–450 PSI (2,000–3,000 kPa)	Within 1 gpm (4 lpm) of straight ahead)
Full turn at stops	750–1,450 PSI** (5,200–10,000 kPa)	Less than 1 gpm (4 lpm)

* Volume is determined by orifice size in the outlet of the pump and is matched to the steering gear.

** Upper-limit pressure is determined by the calibration of the pressure-relief valve.

CHART 117–2

Power steering pressures are related to the force applied to the steering wheel by the driver. The lowest pressure occurs while driving straight and the highest pressure occurs during turns to the steering stops.

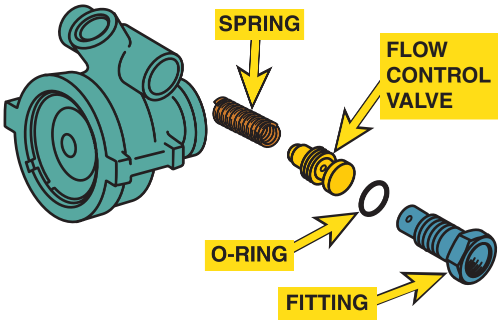

FIGURE 117–34 Typical power steering pump showing the order of assembly. The high-pressure (outlet) hose attaches to the fitting (#16). The flow control valve can be removed from the pump by removing the fitting.

Most power steering pump service requires the removal of the pump from the engine mounting and/or removal of the drive pulley.

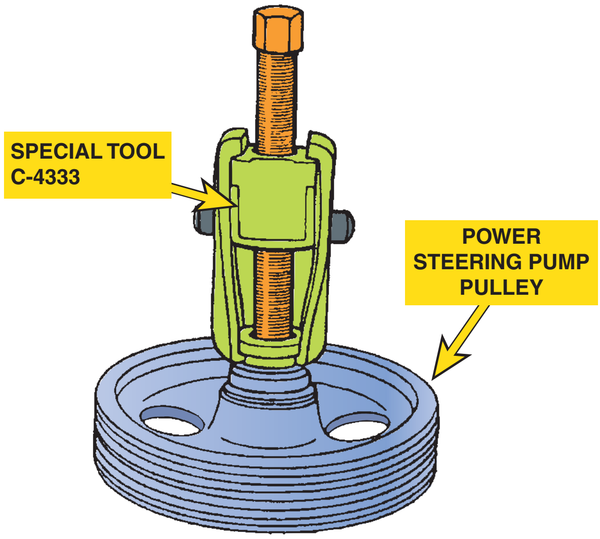
NOTE: Most replacement pumps are not equipped with a pulley. The old pulley must be removed and installed on the new pump. The old pulley should be carefully inspected for dents, cracks, or warpage. If the pulley is damaged, it must be replaced. The pulley must be removed and installed with a pulley removal and installation tool. ● SEE FIGURE 117–35.

CAUTION: Do not hammer the pump shaft or pulley in an attempt to install the pulley. The shock blows will damage the internal components of the pump.

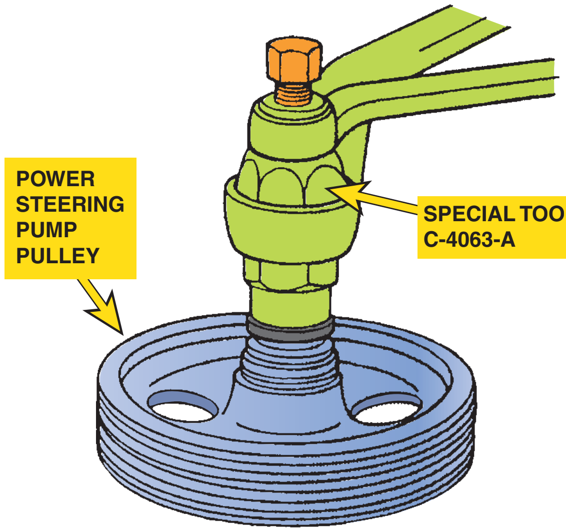
TECH TIP

Pocket the Ignition Key to Be Safe

When replacing any steering gear such as a rack-and-pinion steering unit, be sure that no one accidentally turns the steering wheel! If the steering wheel is turned without being connected to the steering gear, the airbag wire coil (clock spring) can become off center. This can cause the wiring to break when the steering wheel is rotated after the steering gear has been replaced. To help prevent this from occurring, simply remove the ignition key from the ignition (make sure the steering wheel is locked) and put it in your pocket while servicing the steering gear.



REMOVE DRIVE PULLEY (TYPICAL)

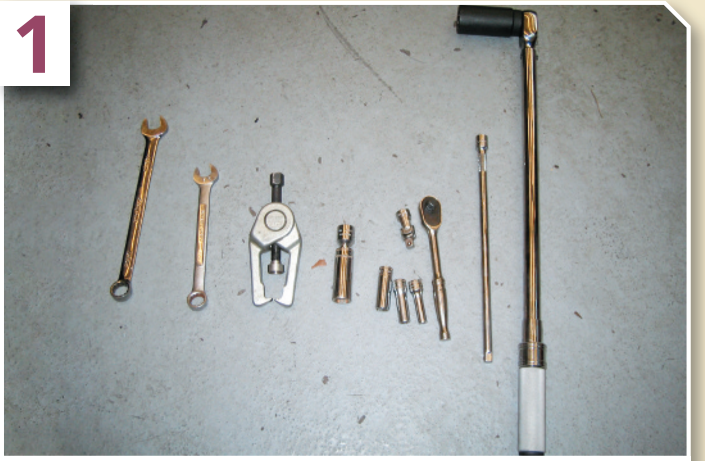


INSTALL DRIVE PULLEY (TYPICAL)

FIGURE 117–35 Typical tools required to remove and install a drive pulley on a power steering pump. Often these tools can be purchased at a relatively low cost from automotive parts stores and will work on many different makes of vehicles.

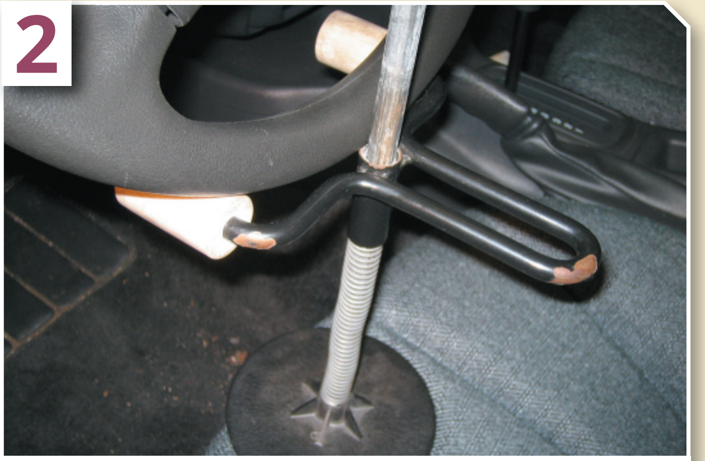
STEERING RACK REMOVAL AND INSTALLATION STEP BY STEP

1



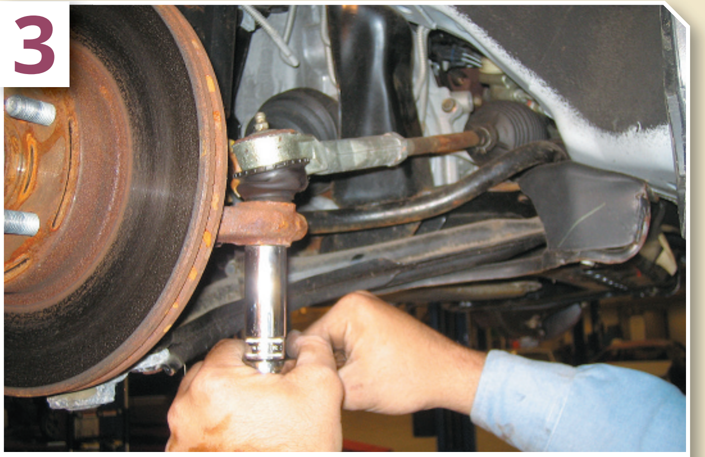
The tools required include a tie rod end puller and basic hand tools.

2



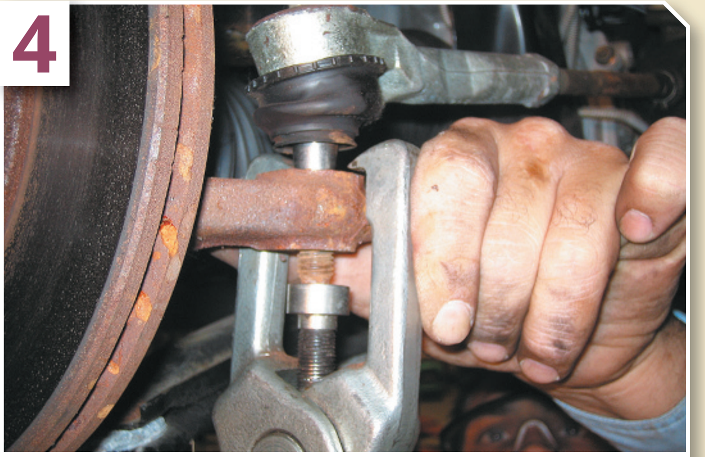
To help keep the steering wheel from rotating when the steering rack assembly is removed, a steering wheel lock is being used.

3



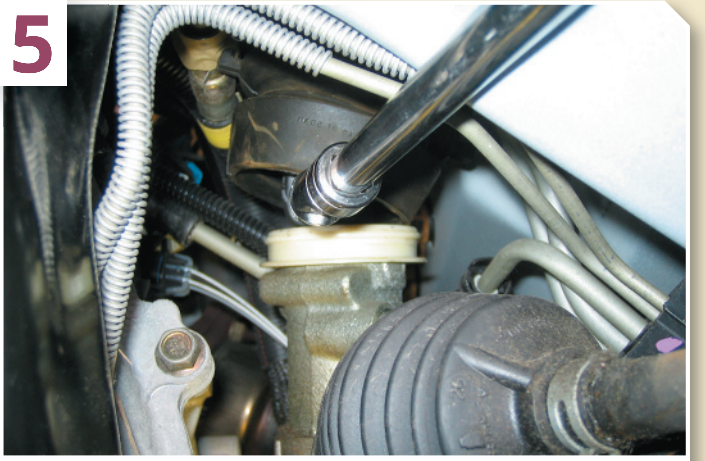
After safely hoisting the vehicle and removing the front wheels, the outer tie rod end retaining nuts are removed.

4



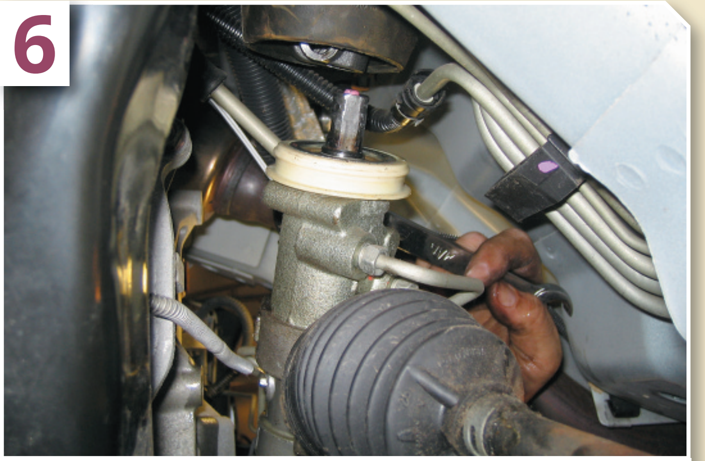
Use a tie rod taper breaker to separate the outer tie rods from the steering knuckle without harming the rubber grease boots.

5



After moving the protective cover aside, the bolt used to retain the intermediate shaft to the steering gear stub shaft is removed.

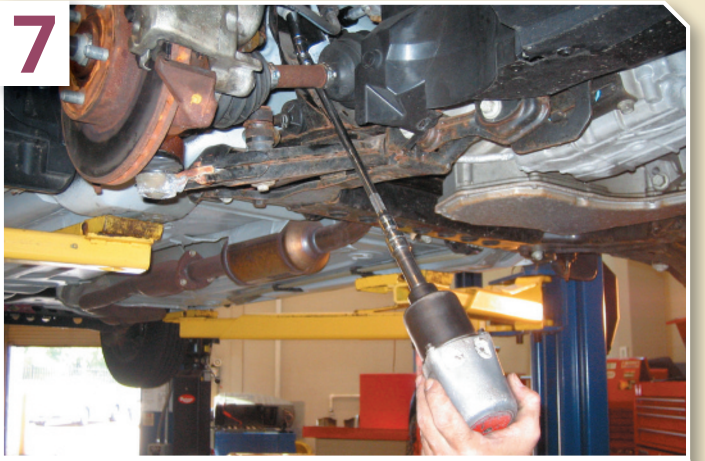
6



The hydraulic lines attached to the steering rack to the power steering rack assembly are removed using a line wrench.

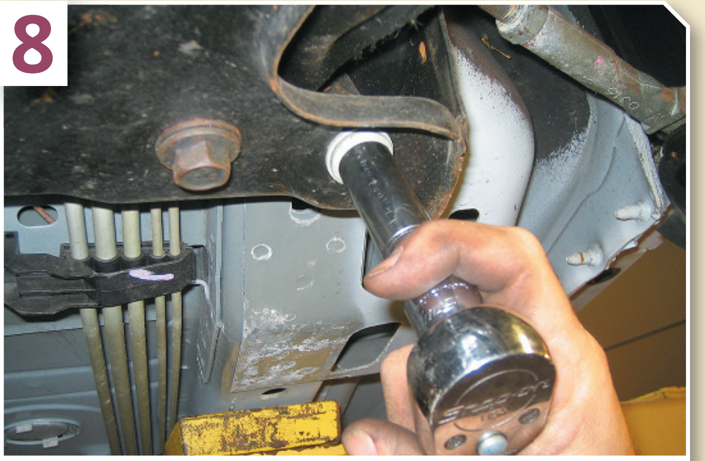
STEERING RACK REMOVAL AND INSTALLATION

7



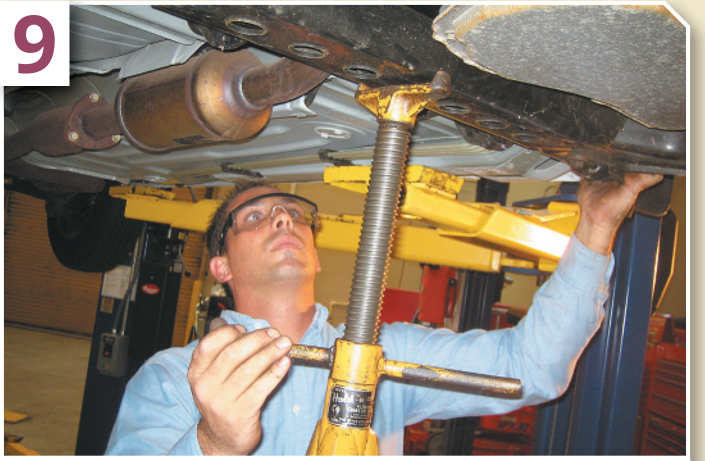
After supporting the engine cradle using a tall safety stand, an air impact wrench with a long extension is used to remove the engine cradle bolts.

8



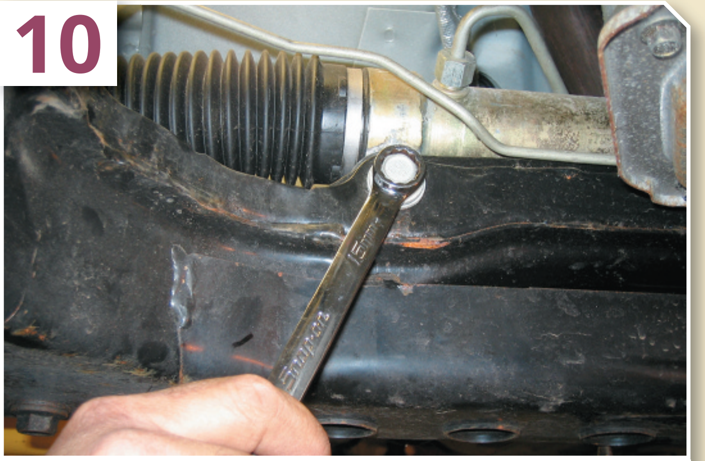
Removing the lower engine cradle bolts. This will allow the cradle to be lowered to gain access to the steering rack assembly.

9



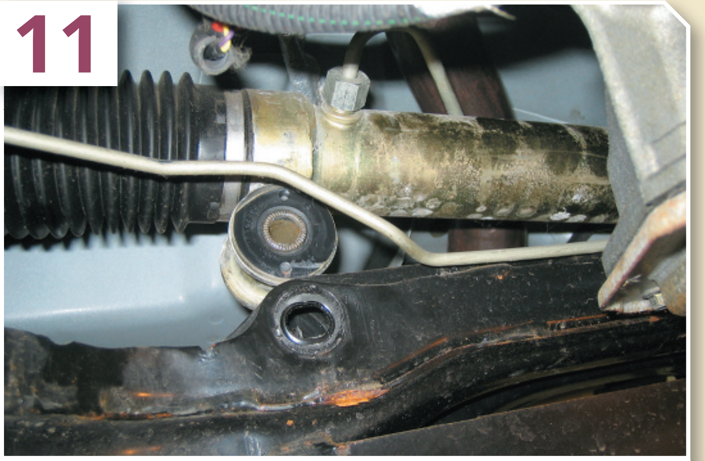
The screw jack on the tall safety stands is rotated allowing the engine cradle to be lowered.

10



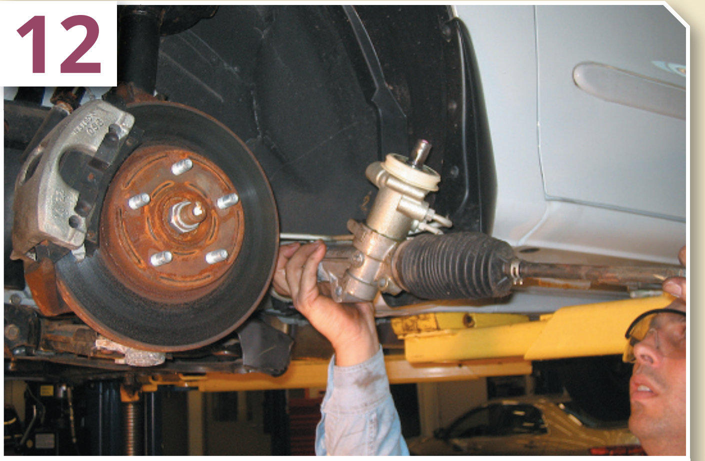
Removing the steering rack attachment bolts.

11



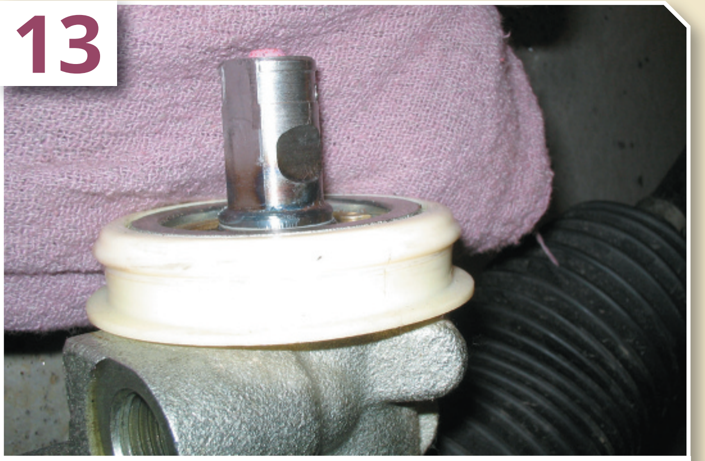
The steering rack assembly can be lifted out of the support brackets.

12



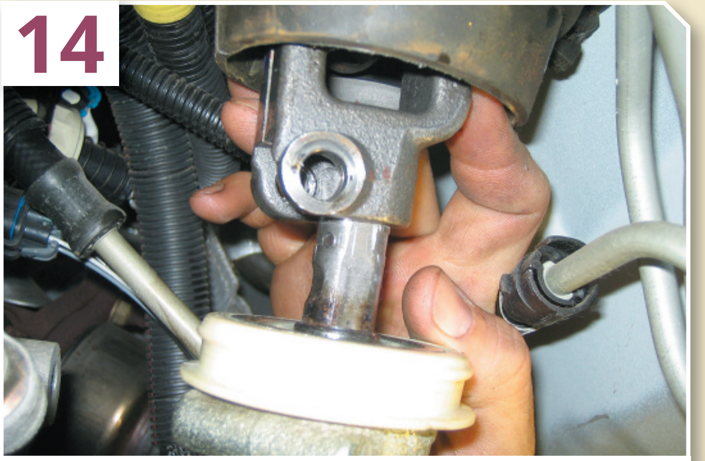
On this General Motors vehicle, the steering rack assembly is removed from the driver's side.

13



Before reinstalling the steering gear assembly, note the notch on the stub shaft. This notch has to be aligned with the intermediate shaft retaining bolt when it is placed back into the vehicle.

14

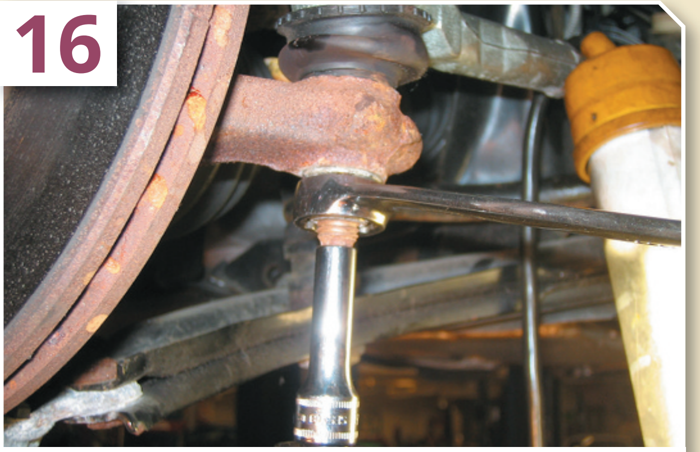


Installation is the reverse of removal. Be sure that the rack is centered and check that the throughbolt is properly aligned with the notch in the steering rack stub shaft.

15

While using a tall safety stand to support the engine cradle, the retaining bolts are installed.

16



A socket is being used to keep the tapered tie rod end from rotating while the retaining nut is tightened with a wrench.

17

After the hydraulic lines and retaining bolts have been installed, the power steering pump reservoir is filled using the specified fluid.

18

To bleed the trapped air out of the system, the steering wheel is rotated lock to lock with engine off and the wheels off the ground. Check for leaks then perform a test-drive to verify a proper repair.

ELECTRIC POWER STEERING SYSTEMS

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Describe the purpose, function, and types of electric power steering systems.
- Discuss electric power steering parts and operation.
- Discuss the power steering control module.
- Discuss the diagnosis of electric power steering system faults.
- Describe the self-parking feature and its relationship to power steering.
- Describe electrohydraulic power steering.

ELECTRIC POWER STEERING OVERVIEW

PURPOSE AND FUNCTION Many of today's vehicles use **electric power steering (EPS)** systems, which is also called **electric power-assisted steering (EPAS)**. Electric power steering takes the place of hydraulic components that were previously used by using an electric motor to provide power assist effort.

ADVANTAGES The advantages include

- Improved fuel economy. Ford and Honda both state that fuel economy improves 3% to 5% in the absence of a power steering pump and the weight of the hydraulic system needed for conventional hydraulically operated power steering systems.
- Increase in usable power. Ford estimates that by using electric power steering instead of a conventional hydraulic system results in a three horsepower increase in engine output without any other changes.
- Allows the vehicle manufacturer to save vehicle weight and complexity because there is no need for all of the hydraulic lines and engine-driven pump.
- Improved cold weather starting because of reduced engine load without the drag of a power steering pump.
- Simple two-wire connection in many cases, making vehicle assembly and vehicle service easier.

TYPES OF EPS SYSTEMS There are two basic types of EPS systems:

1. **Rack mounted.** The rack-mounted system has the assist motor attached to the rack and is often called a **rack-and-pinion electric power steering (R-EPS)** system. Another design has the assist motor surrounding the rack and this style is called a **direct-drive electric power steering (D-EPS)** system. ● **SEE FIGURES 118–1 AND 118–2**.
2. **Column mounted. Column-mounted electric power steering (C-EPS)** has sensors and the assist motor located inside the vehicle so they are not exposed to the heat and outside elements as is the rack-mounted system.

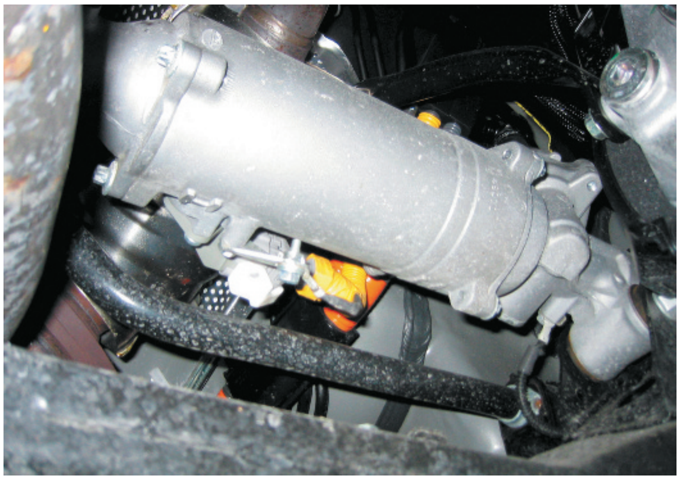

FIGURE 118–1 A rack-mounted electric power steering gear on a Lexus RX 400h taken from underneath the vehicle.

● **SEE FIGURE 118–3**. This is the most commonly used type and involves using a manual rack-and-pinion steering gear assembly with a motor assist in the steering column. While not directly mounted on the column itself, another type of electric power steering is the **pinion-mounted electric power steering (P-EPS)** system. This system has the assist motor connected to the pinion shaft of the rack-and-pinion steering gear. ● **SEE FIGURE 118–4**.

EPS SYSTEM PARTS AND OPERATION

TYPES OF MOTOR USED Most electric power steering units use a DC brushless electric motor. Some operate from 42 volts while others operate from 12 volts. The Toyota system on a Prius uses a DC motor, reduction gear, and torque sensor, all mounted to the steering column. ● **SEE FIGURE 118–5**.

EPS CONTROL UNIT The electric power steering (EPS) is controlled by the EPS electronic control unit (ECU), which calculates the amount of needed assist based on the input from the steering torque sensor. The steering torque sensor is a noncontact sensor that detects the movement and torque applied to the torsion bar. The torsion bar twists when the drive exerts torque to the steering wheel, and the more torque applied, the farther the bar will twist. This generates a higher-voltage signal to the EPS ECU. The EPS control unit can vary the amperage to the assist motor based on input from the torque and steering wheel sensors. The control unit also monitors the temperature of the motor and can reduce the amount of power assist if the motor temperature increases too much. ● **SEE FIGURE 118–6**.

The steering shaft torque sensor and the steering wheel position sensor are serviced as an assembly and are not individually replaceable. The steering column assembly does not include the power steering motor and module assembly. Column-mounted EPS systems use detection rings to measure the differences in relative motion between the upper (input) and lower (output) steering column shafts. Detection rings 1 and 2 are mounted on the input shaft and detection ring 3 is mounted on the output shaft. The input shaft and the output shaft are connected by a torsion bar. When the steering wheel is turned, the difference in relative motion between detection rings 2 and 3 is sensed by the detection coil and it sends two signals to the EPS ECU. These two signals are called Torque Sensor Signal 1 and Torque Sensor Signal 2. The EPS ECU uses these signals to control the amount of assist, and also uses the signals for diagnosis.

NOTE: If the steering wheel, steering column, or steering gear is removed or replaced, the system must be recalibrated, which resets the zero point of the torque sensors.

The Honda electric power steering uses an electric motor to provide steering assist, and torque sensor is used to measure road resistance and the direction that the driver is turning the steering wheel. The torque sensor input and the vehicle speed are used by the EPS controller to supply the EPS motor with

the specified current to help assist the steering effort. ● **SEE FIGURE 118–7**.

The motor turns the pinion shaft using a worm gear. The worm gear is engaged with the worm wheel so that the motor turns the pinion shaft directly when providing steering assist. If a major fault were to occur, the control module would first try to maintain power-assisted steering even if some sensors had failed. If the problem is serious, then the vehicle can be driven and steered manually. The EPS control unit will turn on the EPS dash warning light if a fault has been detected. A fault in the system will *not* cause the malfunction indicator light (MIL) to come on because that light is reserved for emission-related faults only. However, another warning light may be turned on to warn the driver of a problem with the electric power steering system. Fault codes can be retrieved by using a scan tool. Check service information for the exact procedures to follow when diagnosing electric power steering faults.

EPS INPUTS AND OUTPUTS The EPS system includes the following components and input signals from sensors and output signals to actuator components:

- Powertrain control module (PCM)
- Body control module (BCM)
- Power steering control module (PSCM)

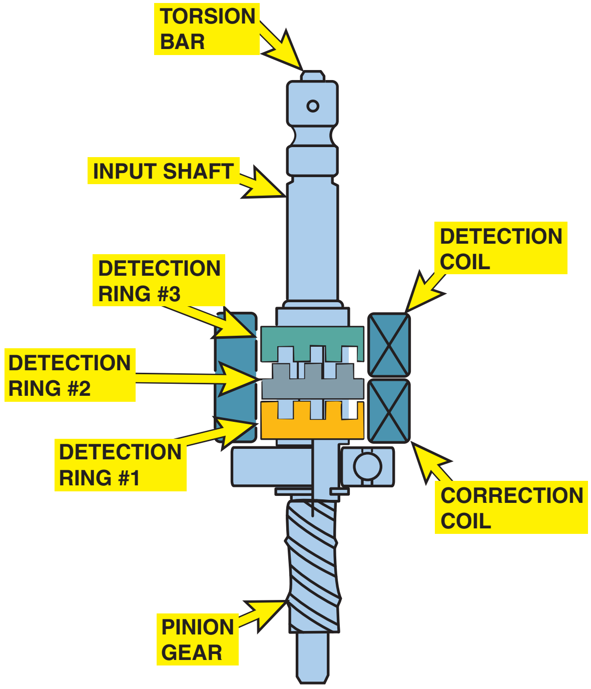

FIGURE 118–6 The torque sensor converts the torque the driver is applying to the steering wheel into a voltage signal.

- Battery voltage
- Steering shaft torque sensor
- Steering wheel position sensor
- Power steering motor
- Driver information center (DIC)
- Serial data communications circuits to perform the system functions

The **power steering control module (PSCM)** and the power steering motor are serviced as an assembly and are serviced separately from the steering column assembly. ● **SEE FIGURE 118–8**.

The steering shaft torque sensor and the steering wheel position sensor are not serviced separately from each other or from the steering column assembly. The steering column assembly does not include the power steering motor and module assembly.

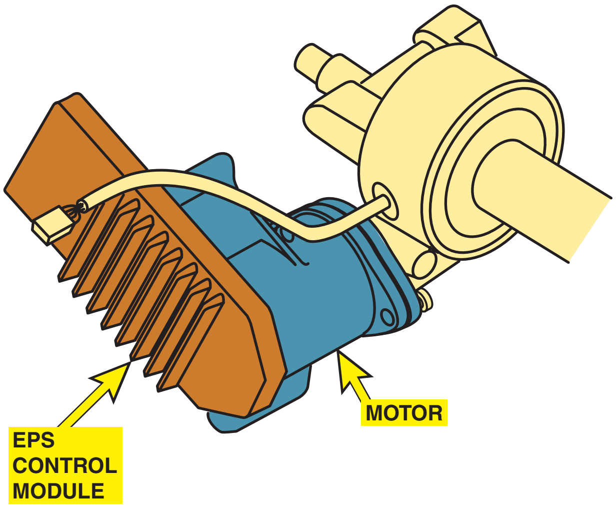

FIGURE 118–8 The power steering control module (PSCM) is attached to the motor of the electric power steering assembly.

STEERING SHAFT TORQUE SENSOR

The PSCM uses the **steering shaft torque sensor** as a main input for determining steering direction and the amount of assist needed. The steering column has an input shaft, from the steering wheel to the torque sensor, and an output shaft, from the torque sensor to the steering shaft coupler. The input and output shafts are separated by a section of torsion bar, where the torque sensor is located. The torque sensor includes two different sensors in one housing. The sensors are used to detect the direction the steering wheel is being rotated.

- When torque is applied to the steering column shaft during a right turn, the sensor signal 1 voltage increases, while the sensor signal 2 voltage decreases.
- When torque is applied to the steering column shaft during a left turn, the sensor signal 1 voltage decreases, while the sensor signal 2 voltage increases.

The PSCM recognizes this change in signal voltage as steering direction and steering column shaft torque.

STEERING WHEEL POSITION SENSOR

The PSCM uses the **steering position sensor (SPS)** to determine the steering system on-center position. Because the power steering motor provides a slight amount of return-to-center assist, the PSCM will command the power steering motor to the steering system center position and not beyond. The sensor is a 5 volt dual-analog signal device with a signal voltage range of 0 to 5 volts. The sensor's signal 1 and signal 2 voltage values will increase and decrease within 2.5 to 2.8 volts of each other as the steering wheel is turned. ● **SEE FIGURE 118–9**.

POWER STEERING MOTOR

The power steering motor is a 12 volt brushless DC reversible motor with a 65 ampere rating. The motor assists steering through a worm gear and reduction gear located in the steering column housing. The motor draws about 750 to 1,000 watts or about 1 horsepower at full assist. The motor itself is usually replaced as an assembly or can be included with the control unit.

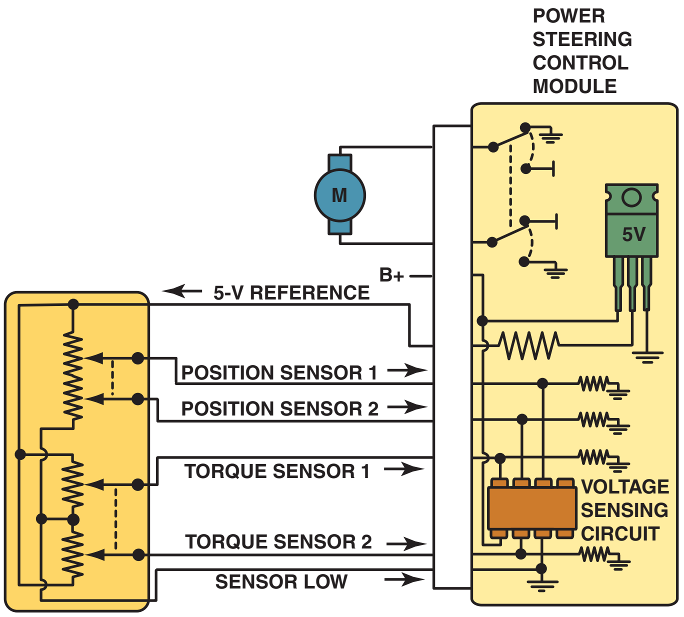

FIGURE 118–9 Schematic showing the electric power steering and the torque/position sensor.

POWER STEERING CONTROL MODULE (PSCM)

PURPOSE AND FUNCTION The PSCM uses a combination of steering shaft torque sensor input, vehicle speed, calculated system temperature, and steering tuning to determine the amount of steering assist.

OPERATION When the steering wheel is turned, the PSCM uses signal voltage from the steering shaft torque sensor to detect the amount of torque and steering direction being applied to the steering column shaft and then commands the proper amount of current to the power steering motor. The PSCM receives a vehicle speed message from the PCM by way of the serial data communications circuit. At low speeds, more assist is provided for easy turning during parking maneuvers, and at higher speeds, less assist is provided for improved road feel and directional stability.

FAULT DETECTION The PSCM and the power steering motor are not designed to handle 65 amperes continuously. If the power steering system is exposed to excessive amounts of static steering conditions, the PSCM will go into a protection mode to avoid thermal damage due to overheating of the power steering components. In this mode, the PSCM will limit the amount of current commanded to the power steering motor, which reduces system temperature and steering assist levels.

EPS DIAGNOSIS

The PSCM has the ability to detect malfunctions within the power steering system. Any malfunction detected will cause the driver information center to display the *power steering* warning message and/or the *service vehicle soon* indicator.

The PSCM must also be set up with the correct steering tunings, which are different in relation to the vehicle's powertrain configuration, model type, and tire and wheel size. A factory or aftermarket factory-level scan tool is needed to retrieve data and to perform relearn procedures if the unit is replaced. Always check service information for the exact procedures to follow when diagnosing and serving the electric power steering system.

DIAGNOSTIC TROUBLE CODE (DTC)	DESCRIPTION OF FAULT
C1511; C1512; C1513; C1514	Torque sensor fault detected
C1521	Short in motor circuit
U0073	EPS control module lost communications

CHART 118–1

Sample diagnostic trouble codes (DTCs) for the electric power steering system.

EPS DTCS Most electric power steering diagnostic trouble codes will be "C" codes for chassis-related faults or "U" codes for data communication faults. ● **SEE CHART 118–1** for same sample DTCs.

SELF-PARKING SYSTEM

PURPOSE AND FUNCTION Several vehicle manufacturers offer a **self-parking** feature that uses the electric power steering to steer the vehicle. The driver has control of the brakes.

SENSORS INVOLVED Most systems use the following sensors:

- Wheel speed sensor (WSS)
- Steering-angle sensor
- Ultrasonic sensors, which are used to plot a course into a parking space

SELF-PARK OPERATION Some systems, such as those manufactured by Valeo for Volkswagen, allow the driver to control the accelerator as well as the brakes, making it possible to add power to park uphill. The Toyota/Lexus system stops working if the accelerator is depressed during a self-parking event. The Toyota/Lexus system is camera-based and uses the navigation system to display the parking spot with touch screen controls. The system displays a green video box to indicate that the spot is large enough and a red box to indicate that the spot is too small. The driver positions a yellow flag on the video screen to mark the front corner of the parking spot and then the vehicle backs into the space at idle speed. The driver may have to complete the parking event by straightening the vehicle and pulling forward in the spot in some vehicles.

DIAGNOSIS AND TESTING Self-parking systems use many sensors to achieve the parking event, and a fault in any one sensor will disable self-parking. Before trying to diagnose a self-parking fault, be sure that the driver is operating the system as designed. For example, the self-parking event is cancelled if the accelerator pedal is depressed on some units. Always follow the factory-recommended diagnostic and testing procedures.

CASE STUDY

The Hard Steering Chevrolet

The owner of a Chevrolet complained that the steering wheel was harder to turn after the battery was jump started. The tow truck driver did not know what to do and advised the owner to take it to a shop to have it looked at but the driver did not think that jump starting the vehicle could affect the power steering. A technician at the shop determined that the electric power steering did not work because of a blown fuse. Apparently, the vehicle was jump started by connecting the positive jump cable to the main terminal toward the rear of the engine compartment instead of the terminal designed to be used to jump start the vehicle as the battery is located at the rear of this vehicle. ● **SEE FIGURE 118–10**.

After the blown fuse was replaced, the electric power steering worked correctly.

Summary:

Complaint—Owner complained that the steering felt stiff after the vehicle was jump started.

Cause—The jump start cables were connected to the wrong terminal, which caused the fuse to blow that controlled the electric power steering.

Correction—The blown fuse was replaced and the power steering system operation was restored to normal.

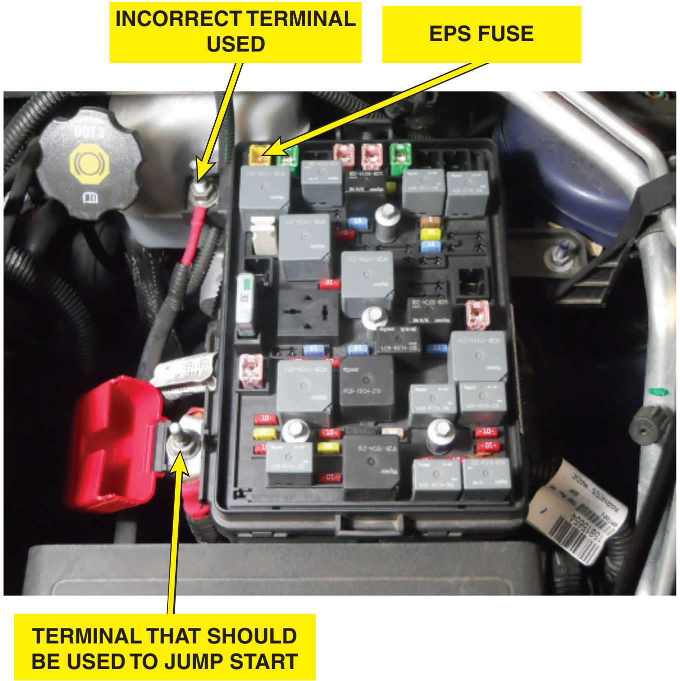

FIGURE 118–10 The blown fuse is the yellow 60 ampere fuse next to the terminal at the top.

ELECTROHYDRAULIC POWER STEERING

PURPOSE AND FUNCTION Electrohydraulic power steering is used on the Chevrolet Silverado mild hybrid truck and on the Mini Cooper. This system uses an electric motor to drive a hydraulic pump. The **electrohydraulic power steering (EHPS)** module controls the power steering motor, which has the function of providing hydraulic power to the brake booster and the steering gear. A secondary function includes the ability to improve fuel economy by operating on a demand basis and the ability to provide speed-dependent variable-effort steering. The EHPS module controls the EHPS power pack, which is an integrated assembly consisting of the following components:

- Electric motor
- Hydraulic pump
- Fluid reservoir
- Reservoir cap
- Fluid-level sensor
- Electronic controller
- Electrical connectors

● **SEE FIGURE 118–11**.

EHPS MODULE The electrohydraulic power steering (EHPS) module is operated from the 36 volt (nominal) power supply. The EHPS module uses class 2 for serial communications. A 125 ampere, 36 volt fuse is used to protect the EHPS module. If this fuse were to blow open, the EHPS system would not operate and communication codes would be set by the modules that communicate with the EHPS module. The powertrain control module (PCM) is the gateway that translates controller area network (CAN) messages into class 2 messages when required for diagnostic purposes. The EHPS module receives the following messages from the CAN bus:

- Vehicle speed
- Service disconnect status

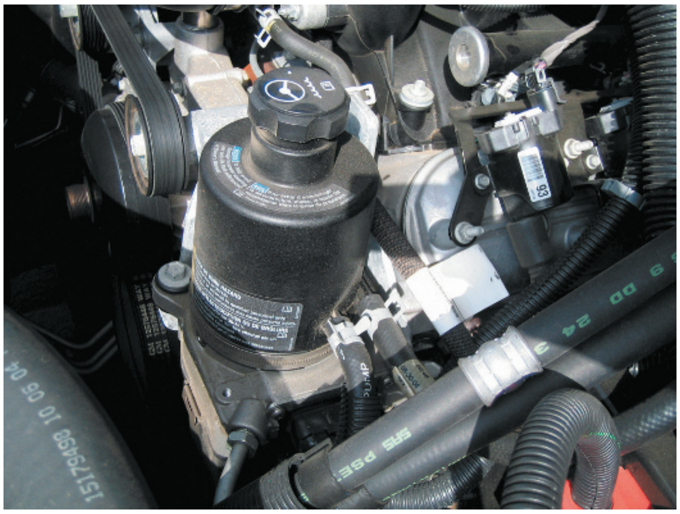

FIGURE 118–11 An electrohydraulic power steering assembly on a Chevrolet hybrid pickup truck.

- PRNDL (shift lever) position
- Torque converter clutch (TCC)/cruise dump signal (gives zero-adjust brake switch position)

The EHPS module receives several signals through wiring. The signals received and used by the EHPS module include

- The digital steering wheel speed signals from the steering wheel sensor mounted on the steering column. The steering wheel speed sensor output contains three digital signals that indicate the steering wheel position. The signals are accurate to within 1 degree. The index output references a steering wheel position of 0 degrees plus or minus 10 degrees (steering wheel centered) and is repeated every 360 degrees of steering wheel rotation.
- An analog brake pedal position signal from the brake pedal–mounted **brake pedal position (BPP) sensor**. The BPP sensor outputs an analog signal, referenced to 5 volts, that increases or decreases with brake pedal depression. The electrical range of the BPP sensor motion is −55 degrees to +25 degrees. The mechanical range of the BPP sensor is −70 degrees to +40 degrees.

DEFINITION OF A WHEEL ALIGNMENT

A wheel alignment is the adjustment of the suspension and steering to ensure proper vehicle handling with minimum tire wear. When a vehicle is new, the alignment angles are set at the factory. After many miles and/or months of driving, the alignment angles can change slightly. The change in alignment angles may result from one or more of the following conditions:

1. Wear of the steering and the suspension components
2. Bent or damaged steering and suspension parts
3. Sagging springs, which can change the ride height of the vehicle and therefore the alignment angles

By adjusting the suspension and steering components, proper alignment angles can be restored. An alignment includes checking and adjusting, if necessary, both front and rear wheels.

ALIGNMENT-RELATED PROBLEMS

Most alignment diagnosis is symptom-based diagnosis. This means that the problem with the alignment is determined from symptoms such as excessive tire wear or a pull to one side of the road.

PULL A **pull** is generally defined as a definite tug on the steering wheel toward the left or the right while driving straight on a level road. ● **SEE FIGURE 119–1**. Bent, damaged, or worn suspension and/or steering components can cause this problem, as well as a tire problem.

LEAD OR DRIFT A **lead** or **drift** is a mild pull that does not cause a force on the steering wheel that the driver must counteract. A lead or drift is observed by momentarily removing your hands

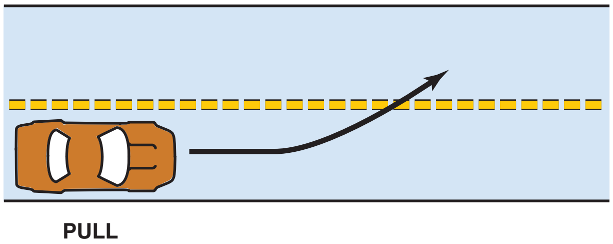

FIGURE 119–1 A pull is usually defined as a tug on the steering wheel toward one side or the other.

from the steering wheel while driving on a straight, level road. When the vehicle moves toward one side or the other, this is called a lead or a drift.

CAUTION: When test-driving a vehicle for a lead or a drift, make sure that the road is free of traffic and that your hands remain close to the steering wheel. Your hands should be held away from the steering wheel for just a second or two—just long enough to check for a lead or drift condition.

ROAD CROWN EFFECTS Most roads are constructed with a slight angle to permit water to drain from the road surface. On a two-lane road, the center of the road is often higher than the berms, resulting in a **road crown**. ● **SEE FIGURE 119–2**.

On a four-lane expressway (freeway), the crown is often *between the two sets* of lanes. Because of this slight angle to the road, some vehicles may lead or drift away from the road crown. In other words, it may be perfectly normal for a vehicle to lead toward the right while being driven in the slow lane and toward the left while being driven in the fast (or inside) lane of a typical divided highway.

WANDER A **wander** is a condition where constant steering wheel corrections are necessary to maintain a straight-ahead direction on a straight, level road. ● **SEE FIGURE 119–3**.

Worn suspension and/or steering components are the most likely cause of this condition. Incorrect or unequal alignment angles such as caster and toe, as well as defective tire(s), can also cause this condition.

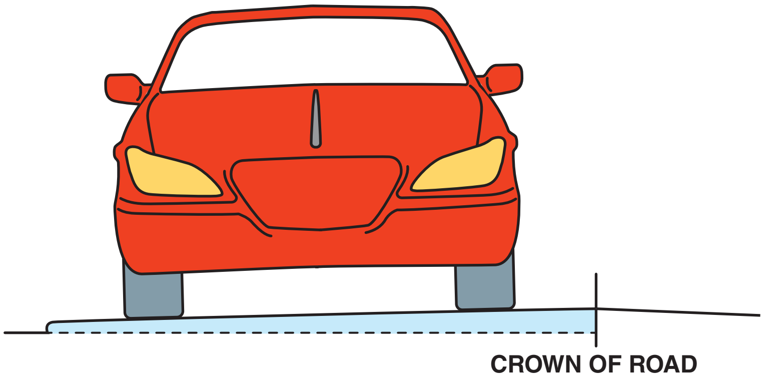

FIGURE 119–2 The crown of the road refers to the angle or slope of the roadway needed to drain water off the pavement.

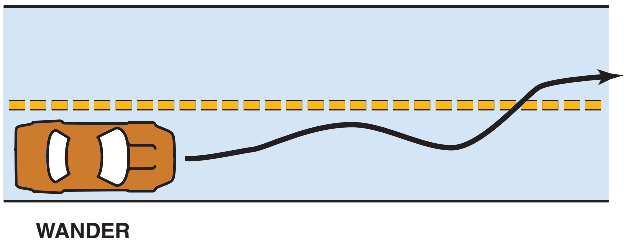

FIGURE 119–3 Wander is an unstable condition requiring constant driver corrections.

STIFF STEERING OR SLOW RETURN TO CENTER Hard-to-steer problems are commonly caused by leaks, either low tire pressure (due to the leak of air) or lack of proper power steering (due to the leak of power steering fluid). Other causes include excessive positive caster on the front wheels or binding steering linkage.

TRAMP OR SHIMMY VIBRATION **Tramp** is a vertical-type (up-and-down) vibration usually caused by out-of-balance or defective tires or wheels. **Shimmy** is a back-and-forth vibration that can be caused by an out-of-balance tire or defective wheel or by an alignment problem.

NOTE: Wheel alignment will not correct a tramp-type vibration.

CAMBER

DEFINITION **Camber** *is the inward or outward tilt of the wheels from true vertical as viewed from the front or rear of the vehicle.*

1. If the top of the tire is tilted out, then camber is positive (+), as shown in ● **FIGURE 119–4**.
2. If the top of the tire is tilted in, then camber is negative (–), as shown in ● **FIGURE 119–5**.

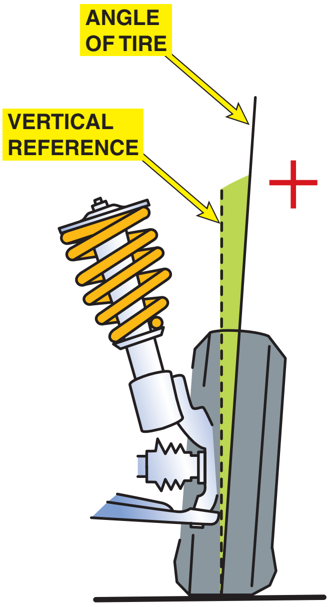

FIGURE 119–4 Positive camber. The dotted line represents true vertical, and the solid line represents the angle of the wheel.

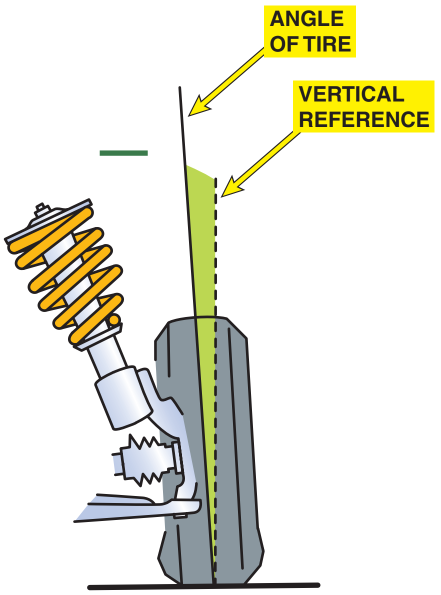

FIGURE 119–5 Negative camber. The dotted line represents true vertical and the solid line represents the angle of the wheel.

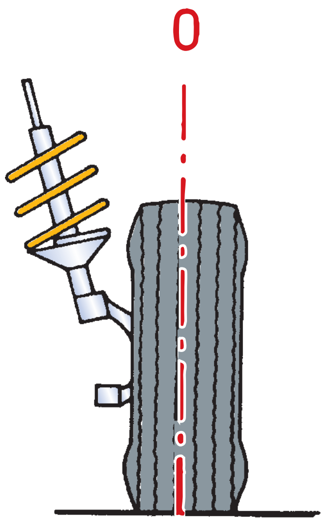

FIGURE 119–6 Zero camber. Note that the angle of the tire is true vertical.

3. Camber is zero (0 degrees) if the tilt of the wheel is true vertical, as shown in ● **FIGURE 119–6**.
4. Camber is measured in degrees or fractions of degrees.
5. *Camber can cause tire wear if not correct.*
   - **a.** *Excessive positive camber* causes scuffing and wear on the outside edge of the tire, as shown in ● **FIGURE 119–7**.
   - **b.** *Excessive negative camber* causes scuffing and wear on the inside edge of the tire, as shown in ● **FIGURE 119–8**.
6. Camber can cause pull if it is unequal side to side. **The vehicle will pull toward the side with the most positive camber.** A difference of more than 1/2 degree from one side to the other will cause the vehicle to pull. ● **SEE FIGURES 119–9 THROUGH 119–11**.
7. Incorrect camber can cause excessive wear on wheel bearings, as shown in ● **FIGURES 119–12 AND 119–13**. Many vehicle manufacturers specify positive camber so that the vehicle's weight is applied to the larger inner wheel bearing and spindle. As the vehicle is loaded or when the springs sag, camber usually decreases. If camber is kept positive, then the running camber is kept near zero degrees for best tire life.

NOTE: Many front-wheel-drive vehicles that use sealed wheel bearings often specify negative camber.

8. Camber is *not* adjustable on many vehicles.
9. If camber is adjustable, the change is made by moving the upper or the lower control arm or strut assembly by means of one of the following methods:
   - **a.** Shims
   - **b.** Eccentric cams
   - **c.** Slots
10. Camber should be equal on both sides; however, if camber cannot be adjusted exactly equal, make certain that there is more camber on the front of the left side to help compensate for the road crown (1/2 degree maximum difference).

WEIGHT OF VEHICLE
POSITIVE CAMBER ANGLE

FIGURE 119–12 Positive camber applies the vehicle weight toward the larger inner wheel bearing. This is desirable because the larger inner bearing is designed to carry more vehicle weight than the smaller outer bearing.

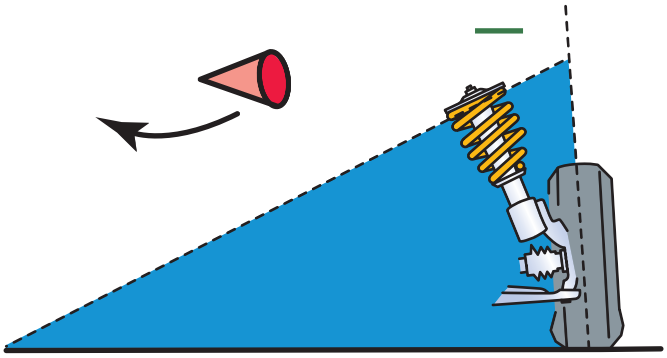

FIGURE 119–10 Negative camber creates a pulling force toward the center of the vehicle.

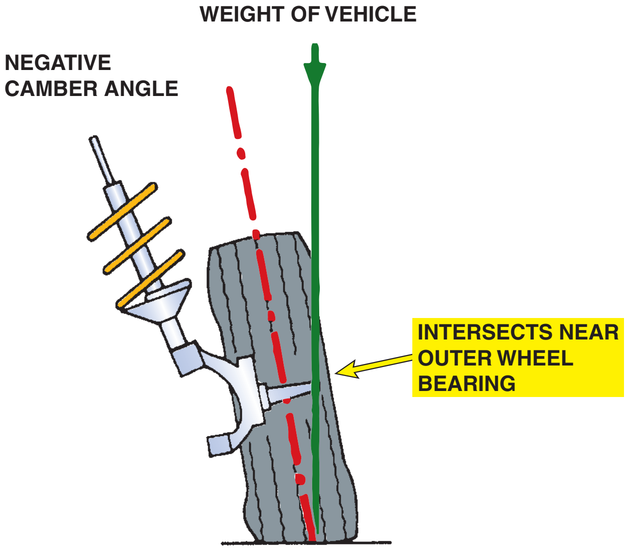

FIGURE 119–13 Negative camber applies the vehicle weight to the smaller outer wheel bearing. Excessive negative camber, therefore, may contribute to outer wheel bearing failure.

CASTER

Caster *is the forward or rearward tilt of the steering axis in reference to a vertical line as viewed from the side of the vehicle*. The steering axis is defined as the line drawn through the upper and lower steering pivot points. On an SLA suspension system, the upper pivot is the upper ball joint and the lower pivot is the lower ball joint. On a MacPherson strut system, the upper pivot is the center of the upper bearing mount and the lower pivot point is the lower ball joint. Zero caster means that the steering axis is straight up and down, also called 0 degrees or perfectly vertical, as shown in ● **FIGURE 119–14**.

1. Positive (+) caster is present when the upper suspension pivot point is behind the lower pivot point (ball joint) as viewed from the side. ● **SEE FIGURE 119–15**.
2. Negative (–) caster is present when the upper suspension pivot point is ahead of the lower pivot point (ball joint) as viewed from the side. ● **SEE FIGURE 119–16**.

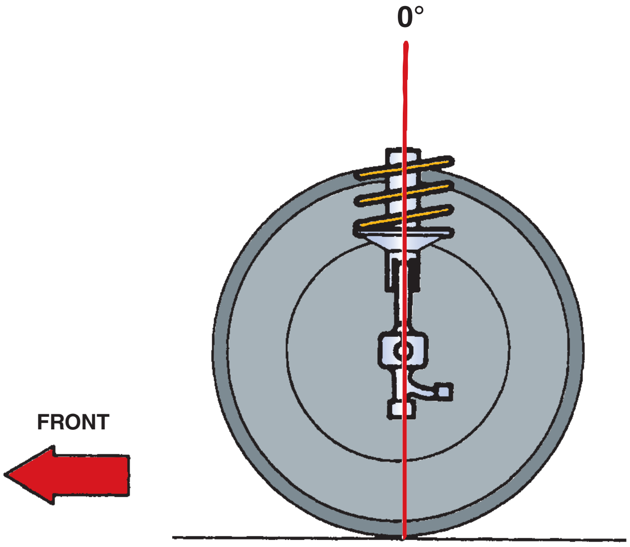

FIGURE 119–14 Zero caster.

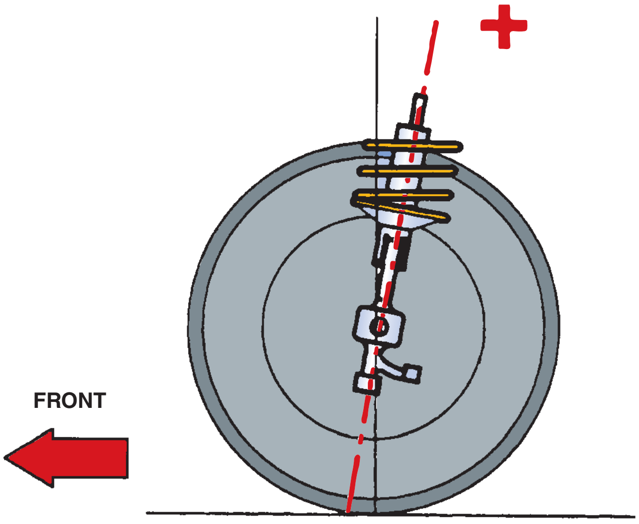

FIGURE 119–15 Positive (+) caster.

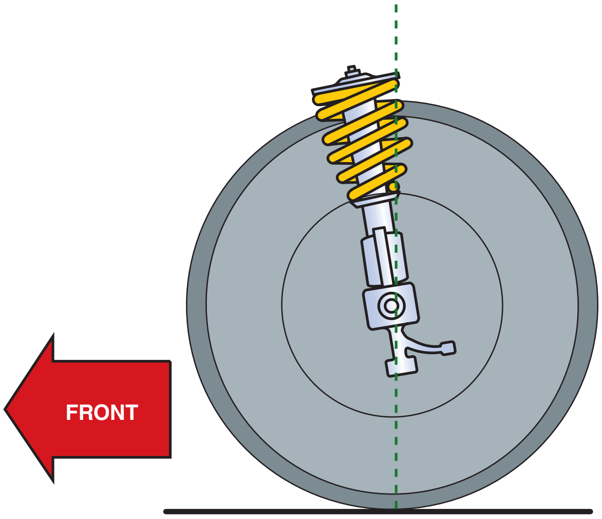

FIGURE 119–16 Negative (–) caster is seldom specified on today's vehicles because it tends to make the vehicle unstable at highway speeds. Negative caster was specified on some older vehicles not equipped with power steering to help reduce the steering effort.

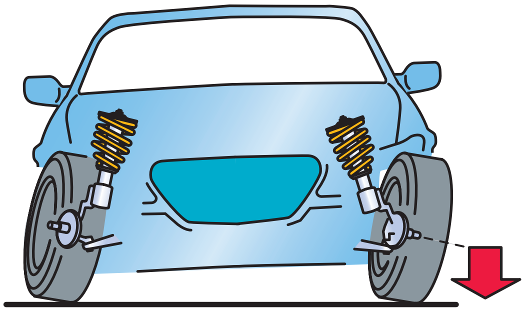

FIGURE 119–17 As the spindle rotates, it lifts the weight of the vehicle due to the angle of the steering axis.

3. Caster is measured in degrees or fractions of degrees.
4. Caster is not a tire-wearing angle, but positive caster does cause changes in camber during a turn. ● **SEE FIGURE 119–17**. This condition is called **camber roll** (see the Tech Tip titled "Caster Angle Tire Wear").

5. Caster is a stability angle.
    a. If caster is positive, the vehicle steering will be very stable (will tend to go straight with little steering wheel correction needed). This degree of caster helps with steering wheel **returnability** after a turn. ● **SEE FIGURE 119–18**.
    b. If the caster is positive, steering effort will increase with increasing positive caster. Greater road shocks will be felt by the driver when driving over rough road surfaces. ● **SEE FIGURE 119–19**. Vehicles with as many as 11 degrees positive caster, such as many Mercedes vehicles, usually use a steering dampener to control possible shimmy at high speeds and to dampen the snap-back of the spindle after a turn. ● **SEE FIGURE 119–20**.
    c. If caster is negative, or excessively unequal, the vehicle will not be as stable and will tend to wander (constant steering wheel movement will be required to maintain straight-ahead direction). If a vehicle is heavily loaded in the rear, caster increases. ● **SEE FIGURE 119–21**.

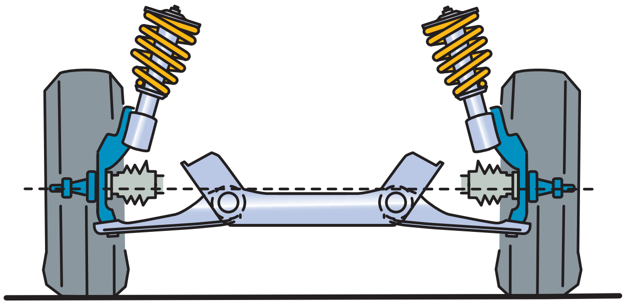

FIGURE 119–18 Vehicle weight tends to lower the spindle, which returns the steering to the straight-ahead position.

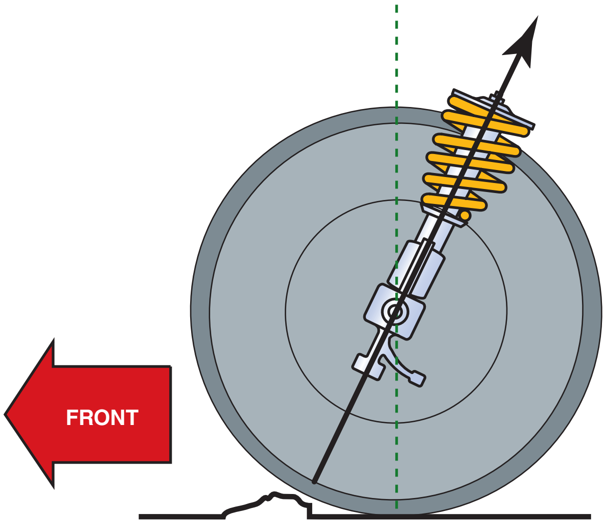

FIGURE 119–19 High caster provides a road shock path to the vehicle.

6. Caster can cause pull if unequal; **the vehicle will pull toward the side with the least positive caster.** However, the pulling force of unequal caster is only about one-fourth the pulling force of camber. It would require a difference of caster of one full degree to equal the pulling force of only 1/4 degree difference of camber.
7. Caster is *not* adjustable on many vehicles.
8. If caster is adjustable, it is changed by moving either the lower or the upper pivot point forward or backward by means of the following:
    a. Shims
    b. Eccentric cams
    c. Slots
    d. Strut rods

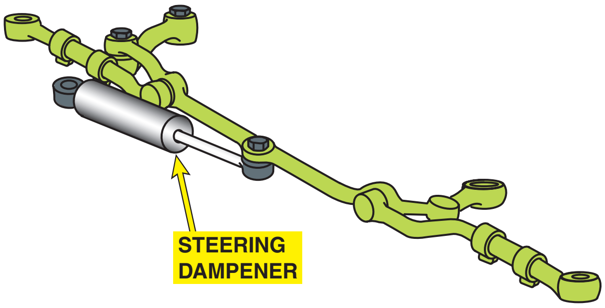

FIGURE 119–20 A **steering dampener** is used on many pickup trucks, sport-utility vehicles (SUVs), and many luxury vehicles designed with a high-positive-caster setting. The dampener helps prevent steering wheel kickback when the front tires hit a bump or hole in the road and also helps reduce steering wheel shimmy that may result from the high-caster setting.

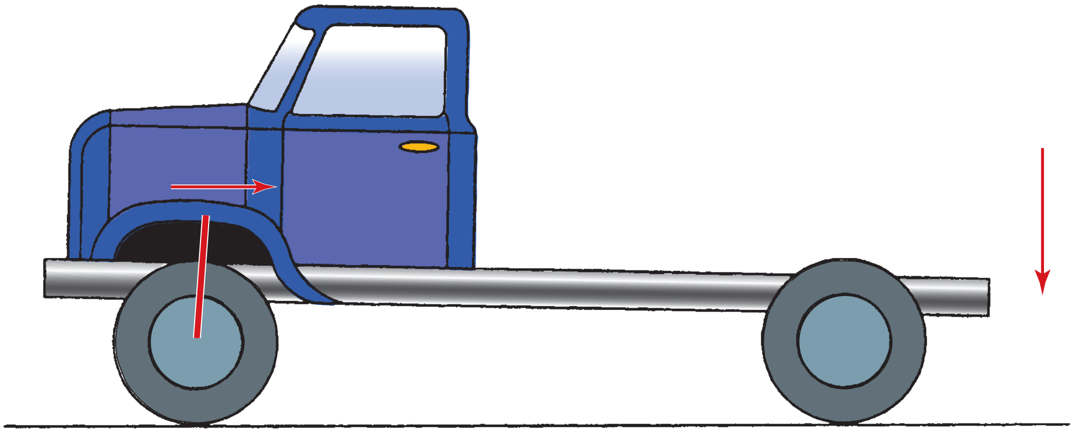

FIGURE 119–21 As the load increases in the rear of a vehicle, the top steering axis pivot point moves rearward, increasing positive (+) caster.

TECH TIP

Caster Angle Tire Wear

The caster angle is generally considered to be a *non-tire-wearing angle*. However, excessive or unequal caster can *indirectly* cause tire wear. When the front wheels are turned on a vehicle with a lot of positive caster, they become angled. This is called *camber roll*. (Caster angle is a measurement of the difference in camber angle from when the wheel is turned inward compared to when the wheel is turned outward.) Most vehicle manufacturers have positive caster designed into the suspension system. This positive caster increases the directional stability.

However, if the vehicle is used exclusively in city driving, positive caster can cause tire wear to the outside shoulders of both front tires. ● **SEE FIGURE 119–22**.

TECH TIP

Think of a Bicycle

How caster affects steering stability and steering wheel returning to the straight-ahead position after a turn is made easy by remembering how a bicycle acts. Caster allows riders to travel straight ahead with their hands off the handle bars because the weight is behind the axle.

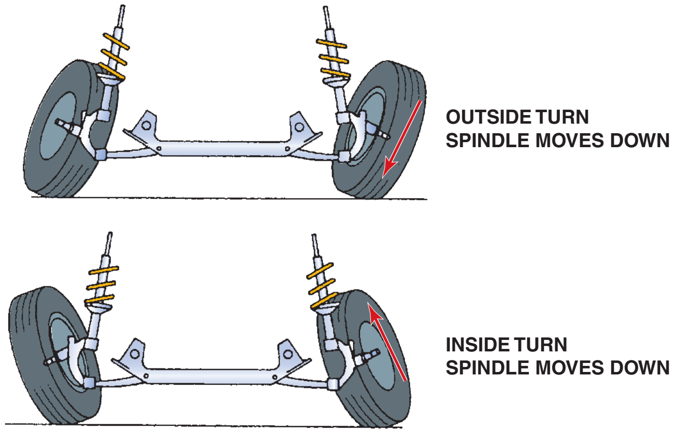

FIGURE 119–22 Note how the front tire becomes tilted as the vehicle turns a corner with positive caster. The higher the caster angle, the more the front tires tilt, causing camber-type tire wear.

9. Caster should be equal on both sides; however, if caster cannot be adjusted to be exactly equal, make certain that there is more caster on the right side (maximum 1/2 degree difference) to help compensate for the crown of the road.

NOTE: Caster is only measured on the front turning wheels of the vehicle. While some caster is built into the rear suspension of many vehicles, rear caster is not measured as part of a four-wheel alignment.

TOE

Toe *is the difference in distance between the front and rear of the tires*. Toe is the most important of the alignment angles. As viewed from the top of the vehicle (a bird's-eye view), zero toe means that both wheels on the same axle are parallel, as shown in ● **FIGURE 119–23**.

Toe is also described as a comparison of horizontal lines drawn through both wheels on the same axle, as shown in ● **FIGURE 119–24**.

If the front of the tires is closer than the rear of the same tires, then the toe is called *toe-in* or positive (+) toe. ● **SEE FIGURE 119–25**.

If the front of the tires is farther apart than the rear of the same tires, then the wheels are *toed-out,* or have negative (–) toe. ● **SEE FIGURE 119–26**.

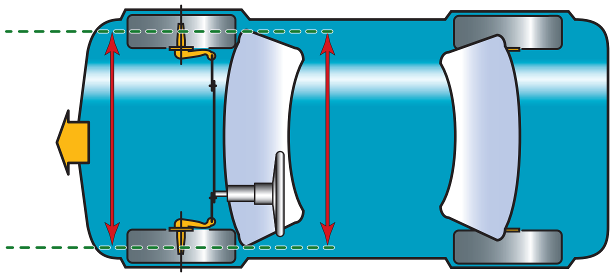

FIGURE 119–23 Zero toe. Note how both tires are parallel to each other as viewed from above the vehicle.

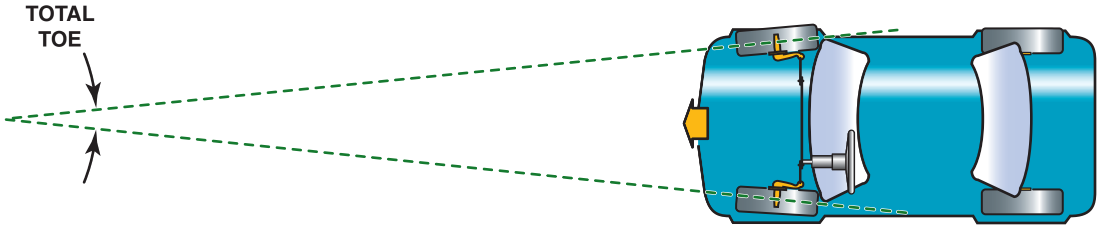

FIGURE 119–24 Total toe is often expressed as an angle. Because both front wheels are tied together through the tie rods and center link, the toe angle is always equally split between the two front wheels when the vehicle moves forward.

The purpose of the correct toe setting is to provide maximum stability with a minimum of tire wear when the vehicle is being driven.

1. Toe is measured in fractions of degrees or in fractions of an inch (usually 1/16 s), millimeters (mm), or decimals of an inch (such as 0.06 inch).
2. *Incorrect toe is the major cause of excessive tire wear!* ● **SEE FIGURE 119–27**.

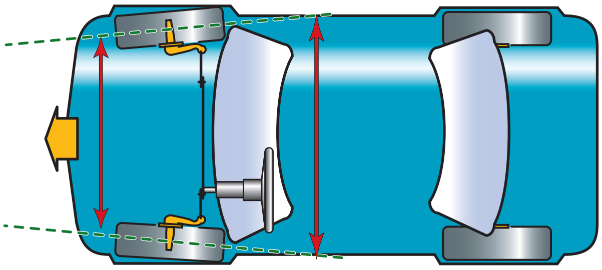

FIGURE 119–25 Toe-in, also called positive (+) toe.

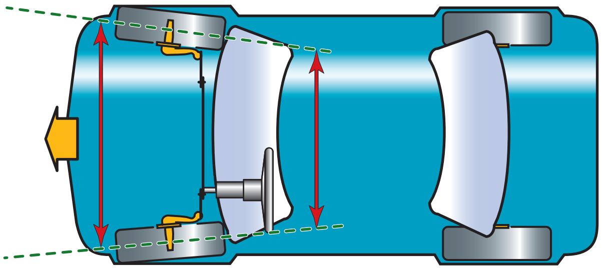

FIGURE 119–26 Toe-out, also called negative (–) toe.

NOTE: If the toe is improper by just 1/8 inch (3 mm), the resulting tire wear is equivalent to dragging a tire sideways 28 feet (8.5 m) for every mile traveled (1.6 km).

If not correct, toe causes camber-type wear on one side of the tire. ● **SEE FIGURES 119–28 AND 119–29**. Feather-edge wear is also common, especially if the vehicle is equipped with nonradial tires. ● **SEE FIGURE 119–30**.

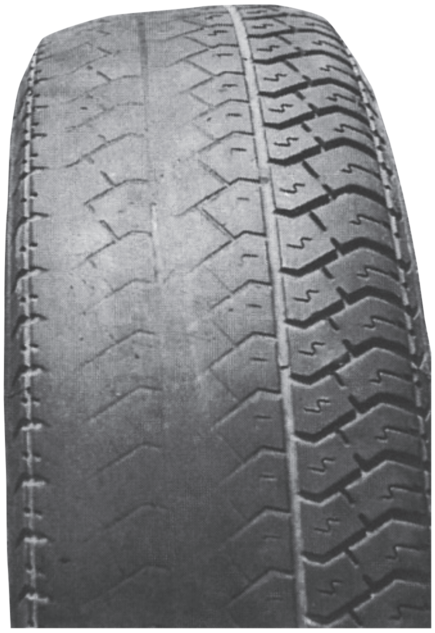

FIGURE 119–27 This tire is just one month old! It was new and installed on the front of a vehicle that had about 1/4 inch (6 mm)of toe-out. By the time the customer returned to the tire store for an alignment, the tire was completely bald on the inside. Note the almost new tread on the outside.

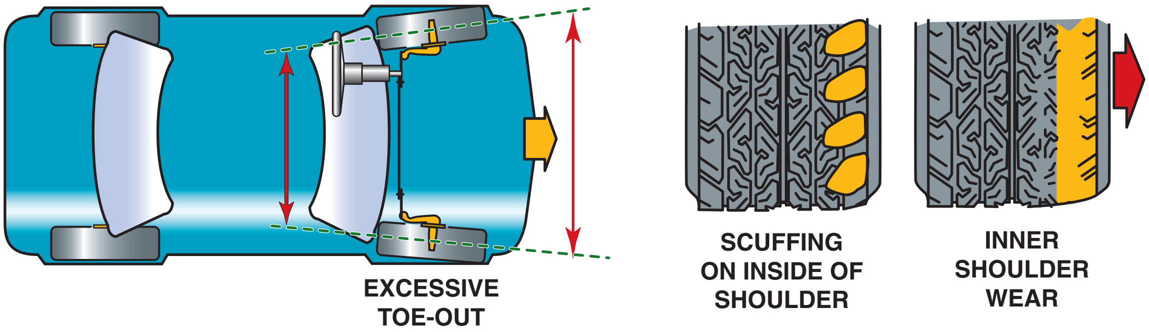

FIGURE 119–28 Excessive toe-out and the type of wear that can occur to the side of both front tires.

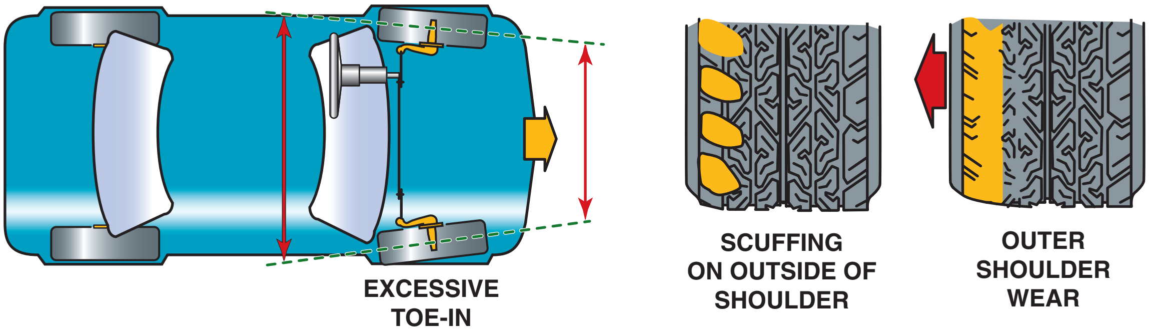

FIGURE 119–29 Excessive toe-in and the type of wear that can occur to the outside of both front tires.

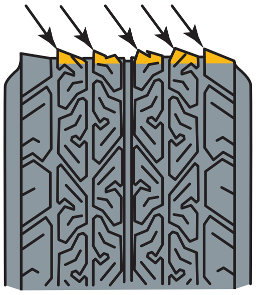

FIGURE 119–30 Feather-edge wear pattern caused by excessive toe-in or toe-out.

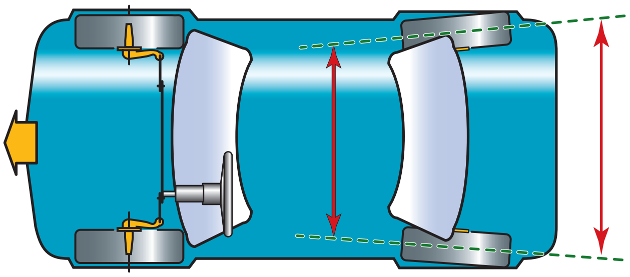

FIGURE 119–31 Rear toe-in (+). The rear toe (unlike the front toe) can be different for each wheel while the vehicle is moving forward because the rear wheels are not tied together as they are in the front.

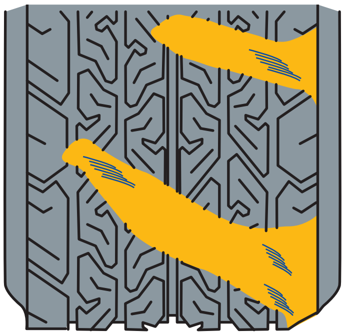

FIGURE 119–32 Incorrect toe can cause the tire to run sideways as it rolls, resulting in a diagonal wipe.

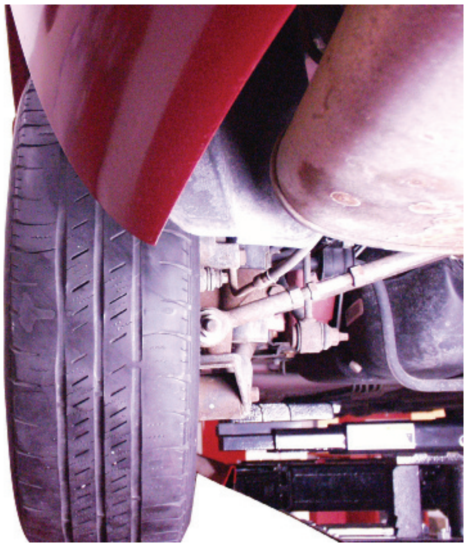

FIGURE 119–33 Diagonal wear such as shown here is usually caused by incorrect toe on the rear of a front-wheel-drive vehicle.

3. *Incorrect front toe does not cause a pull condition*. Incorrect toe on the front wheels is split equally as the vehicle is driven because the forces acting on the tires are exerted through the tie rod and steering linkage to both wheels.
4. *Incorrect (or unequal) rear toe can cause tire wear*. ● **SEE FIGURES 119–31 THROUGH 119–33**. If the toe of the rear wheels is not equal, the steering wheel will not be straight and will pull toward the side with the most toe-in.

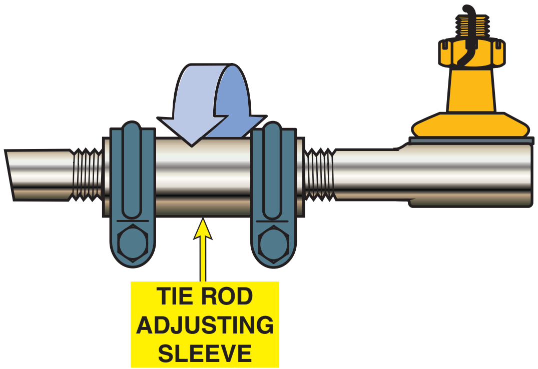

FIGURE 119–34 Toe on the front of most vehicles is adjusted by turning the tie rod sleeve, as shown.

5. All vehicles can be adjusted for front toe.
6. Front toe adjustment must be made correctly by adjusting the tie rod sleeves. ● **SEE FIGURE 119–34**.
7. Many vehicle manufacturers specify a slight amount of toe-in to compensate for the natural tendency of the front wheels to spread apart (become toed-out) due to centrifugal force of the rolling wheels acting on the steering linkage.

NOTE: Some manufacturers of front-wheel-drive vehicles specify a toe-out setting to compensate for the toe-in forces created by the engine drive forces on the front wheels.

8. Normal wear to the tie rod ends and other steering linkage parts usually causes toe-out.

Excessive front toe-out will cause wandering (lack of directional stability), especially during braking. Incorrectly set toe will cause an uncentered steering wheel. If toe is unequal in the *rear*, the vehicle will pull toward the side with the most toe-in.

FREQUENTLY ASKED QUESTION

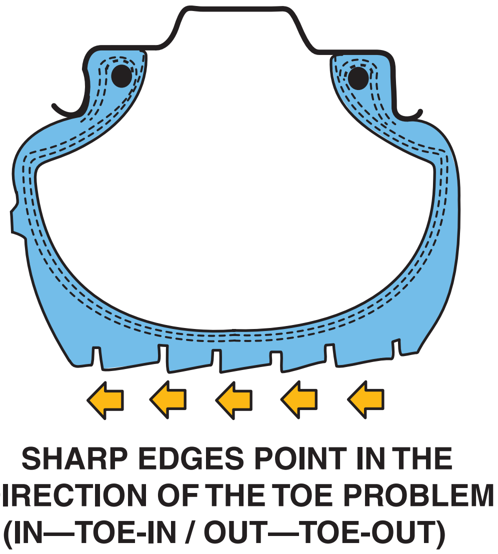
Why Doesn't Unequal Front Toe on the Front Wheels Cause the Vehicle to Pull?

Each wheel could have individual toe, but as the vehicle is being driven, the forces on the tires tend to split the toe, causing the steering wheel to cock at an angle as the front wheels both track the same. If the toe is different on the rear of the vehicle, the rear will be "steered" similar to a rudder on a boat because the rear wheels are not tied together as are the front wheels.

TECH TIP

Smooth In, Toed-In; Smooth Out, Toed-Out

Whenever the toe setting is not zero, a rubbing action occurs that causes a feather-edge-type wear. ● **SEE FIGURE 119–35**. A quick, easy method to determine if incorrect toe could be causing problems is simply to rub your hand across the tread of the tire. If it feels smoother moving your hand toward the center of the vehicle than when you move your hand toward the outside, then the cause is excessive toe-in. The opposite effect is caused by toe-out. This may be felt on all types of tires, including radial-ply tires where the wear may not be seen as feather edged. Just remember this simple saying: "Smooth in, toed-in; smooth out, toed-out."



SHARP EDGES POINT IN THE DIRECTION OF THE TOE PROBLEM (IN—TOE-IN / OUT—TOE-OUT)

FIGURE 119–35 While the feathered or sawtooth tire tread wear pattern may not be noticeable to the eye, this wear can usually be felt by rubbing your hand across the tread of the tire.

STEERING AXIS INCLINATION

The steering axis is the angle formed between true vertical and an imaginary line drawn between the upper and lower pivot points of the spindle. ● **SEE FIGURE 119–36. Steering axis inclination (SAI)** is the inward tilt of the steering axis. SAI is also known as **kingpin inclination (KPI)** and is the imaginary line drawn through the kingpin as viewed from the front. SAI is also called **ball-joint inclination (BJI)**, if SLA-type suspension is used, or **MacPherson strut inclination (MSI)**.

The purpose of SAI is to provide an upper suspension pivot location that causes the spindle to travel in an arc when turning, which tends to raise the vehicle, as shown in ● **FIGURE 119–37**.

Vehicle weight tends to keep the front wheels in a straight-ahead position when driving, thereby increasing vehicle stability, directional control, and steering wheel returnability. The greater the SAI, the more stable the vehicle. It also helps center the steering wheel after making a turn and reduces the need for excessive positive caster. The SAI/KPI angle of all vehicles ranges between 2 and 16 degrees. Front-wheel-drive vehicles usually have greater than 9 degrees SAI (typically 12 to 16 degrees) for directional stability, whereas rear-wheel-drive vehicles usually have less than 8 degrees of SAI. The steering axis inclination angle and the camber angle together are called the *included angle*.

INCLUDED ANGLE

The **included angle** is the SAI added to the camber reading of the front wheels only. *The included angle is determined by the design of the steering knuckle, or strut construction*. ● **SEE FIGURES 119–38 AND 119–39**.

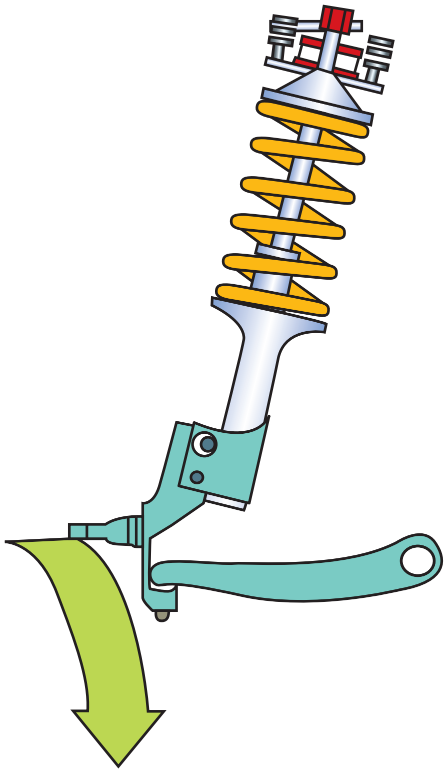


FIGURE 119–37 The SAI causes the spindle to travel in an arc when the wheels are turned. The weight of the vehicle is therefore used to help straighten the front tires after a turn and to help give directional stability.

FIGURE 119–40 Cradle placement. If the cradle is not replaced in the exact position after removal for a transmission or clutch replacement, the SAI, camber, and included angle will not be equal side to side.

The included angle is an important angle to measure for diagnosis of vehicle handling or tire wear problems. For example, if the cradle is out of location due to previous service work or an accident, knowing SAI, camber, and the included angle can help in determining what needs to be done to correct the problem.

● **FIGURE 119–40** shows the included angle is equal on both sides but the camber and SAI are not equal. For best handling, both the included angle and SAI should be within 1/2 degree of the other side of the vehicle.

SCRUB RADIUS

Scrub radius refers to the *distance* between the line through the steering axis and the centerline of the wheel at the contact point with the road surface. ● **SEE FIGURE 119–41**.

Scrub radius is *not* adjustable and cannot be measured. Scrub radius can be zero, positive, or negative. Zero scrub radius means that the line through the steering axis intersects the centerline of the tire at the road surface. Positive scrub radius means

RIGHT FRONT TIRE VIEWED FROM ABOVE

FIGURE 119–43 With a positive scrub radius, the pivot point, marked with a + mark, is inside the centerline of the tire and will cause the wheel to turn toward the outside, especially during braking. Zero scrub radius does not create any force on the tires and is not usually used on vehicles because it does not create an opposing force on the tires, which in turn makes the vehicle more susceptible to minor bumps and dips in the road. Negative scrub radius, as is used with most front-wheel-drive vehicles, generates an inward force on the tires.

that the line intersects the centerline of the tire below the road surface. Negative scrub radius means that the line intersects the centerline of the tire above the road surface. Scrub radius is also called **steering offset** by some vehicle manufacturers. If a wheel is permitted to roll rather than pivot, then steering will be more difficult because a tire can pivot more easily than it can roll while turning the front wheels. If the point of intersection is inside the centerline of the tire and below the road surface, this creates a toe-out force on the front wheels. Negative scrub radius is required on front-wheel-drive vehicles to provide good steering stability during braking. ● **SEE FIGURES 119–42 AND 119–43.**

Scrub radius is designed into each vehicle to provide acceptable handling and steering control under most conditions. Scrub radius also causes resistance to rolling of the front wheels to exert force on the steering linkage. This tends to dampen the effect of minor movements of the front wheels. Negative scrub radius causes the tire to toe-in during acceleration, braking, or traveling over bumps.

NOTE: It is this tendency to toe-in caused by the negative scrub radius and engine torque that requires many front-wheel-drive vehicles to specify a toe-out setting for the front-drive wheels.

Zero scrub radius is acceptable; positive scrub radius is less desirable because it causes the wheel to toe-out during acceleration, braking, or traveling over bumps and causes instability. Positive scrub radius is commonly used on rear-wheel-drive vehicles and requires a toe-in setting to help compensate for the tendency to toe-out.

A bent spindle can cause a change in the scrub radius and could cause hard steering, wander, or pull.

Also, changing tire or wheel sizes can affect the centerline location of the wheel or the height of the tire assembly and will change the scrub radius, which can negatively affect the steering control. When larger-diameter tires and positive-offset wheels are installed, the scrub radius becomes positive and the wheels tend to toe-out, causing wander, poor handling, and tire wear.

TURNING RADIUS (TOE-OUT ON TURNS)

Whenever a vehicle turns a corner, the inside wheel has to turn at a sharper angle than the outside wheel because the inside wheel has a shorter distance to travel. ● **SEE FIGURE 119–44.**

Turning radius is also called **toe-out on turns**, abbreviated TOT or **TOOT**, and is determined by the angle of the steering knuckle arms. **Turning radius is a nonadjustable angle.**

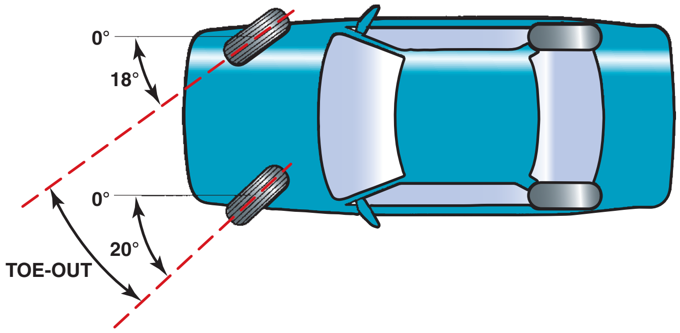

FIGURE 119–44 To provide handling, the inside wheel has to turn at a greater turning radius than the outside wheel.

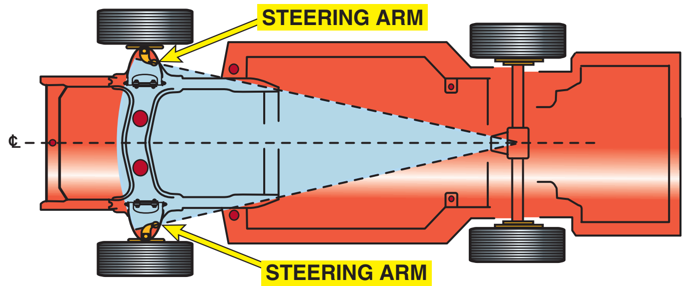

FIGURE 119–45 The proper toe-out on turns is achieved by angling the steering arms.

The turning radius can and should be measured as part of an alignment to check if the steering arms are bent or damaged. Symptoms of out-of-specification turning angle include the following:

1. Tire squeal noise during normal cornering, even at low speeds
2. Scuffed tire wear

The proper angle of the steering arms is where imaginary lines drawn from the steering arms should intersect exactly at the center of the rear axle. ● **SEE FIGURE 119–45**. This angle is called the Ackerman Effect (named for its promoter, an English publisher, Rudolph Ackerman, circa 1898).

SETBACK

Setback is the angle formed by a line drawn perpendicular (at 90 degrees) to the front axles. ● **SEE FIGURE 119–46**.

Setback is a nonadjustable measurement, even though it may be corrected. Positive setback means the right front wheel is set back farther than the left; negative setback means the left front wheel is set back farther than the right.

Setback can be measured with a four-wheel alignment machine or can be determined by measuring the wheel base on both sides of the vehicle.

NOTE: The wheel base of any vehicle is the distance between the center of the front wheel and the center of the rear wheel on the same side. The wheel base should be within 1/8 inch (3 mm) side to side.

The causes of setback include the following:

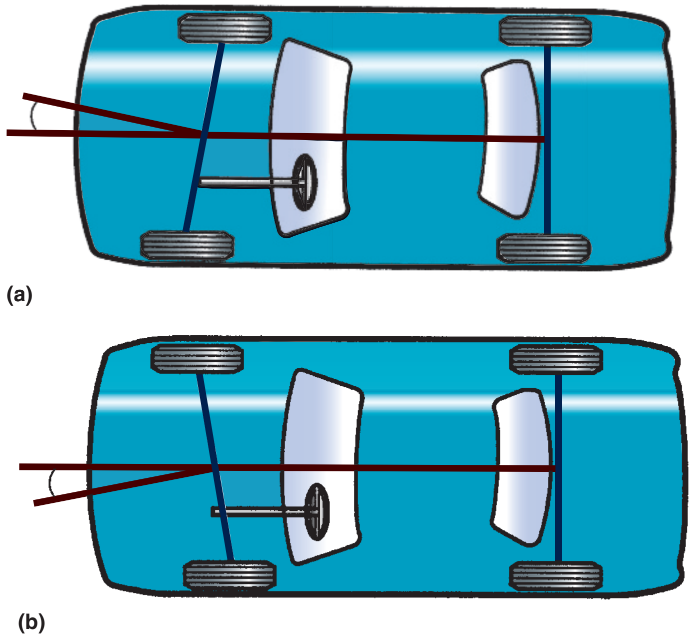

FIGURE 119–46 (a) Positive setback. (b) Negative setback.

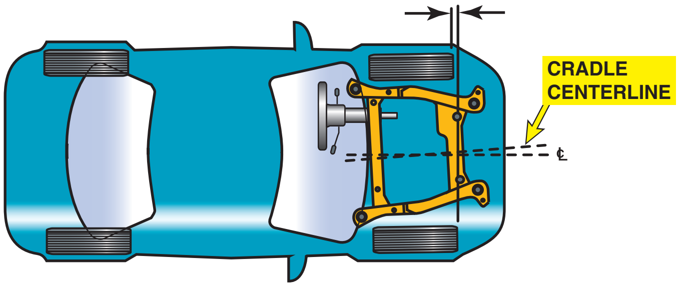

FIGURE 119–47 Cradle placement affects setback.

1. Cradle placement not correct on a front-wheel-drive vehicle. This can be caused by incorrectly installing the cradle after a transmission, clutch, or engine replacement or service. ● **SEE FIGURE 119–47**.
2. An accident that affected the frame or cradle of the vehicle and was unnoticed or not repaired.

Most vehicle manufacturers do not specify a minimum setback specification. However, a reading of 0.50 degrees or 0.5 inch (13 mm) or less of setback is generally considered to be acceptable.

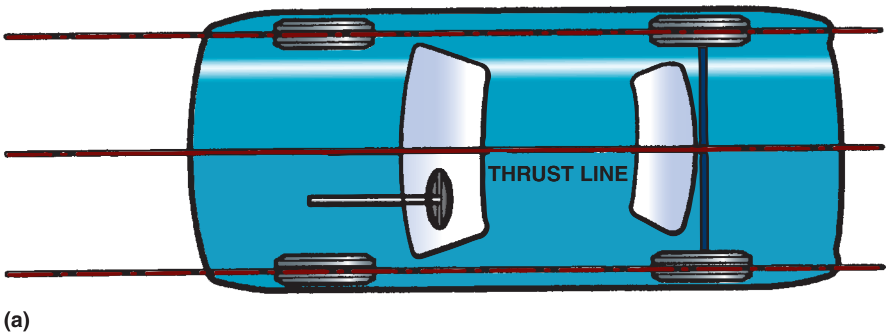
THRUST ANGLE

Thrust angle is the angle of the rear wheels as determined by the total rear toe. If both rear wheels have zero toe, then the thrust angle is the same as the geometric centerline of the vehicle. The total of the rear toe setting determines the **thrust line**, or the direction the rear wheels are pointed. ● **SEE FIGURE 119–48**.

On vehicles with an independent rear suspension, if both wheels do not have equal toe, the vehicle will pull in the direction of the side with the most toe-in.

TRACKING

The rear wheels should track directly behind the front wheels. If the vehicle has been involved in an accident, it is possible that the frame or rear axle mounting could cause **dog tracking**.



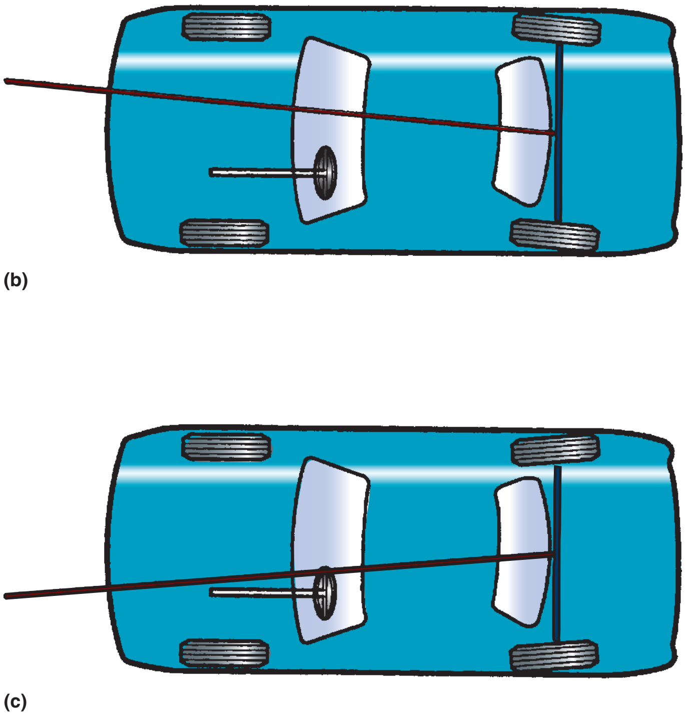


FIGURE 119–48 (a) Zero thrust angle. (b) Thrust line to the right. (c) Thrust line to the left.

Dog tracking is an alignment condition that is caused by having the rear wheel toe angles out of line with the front wheels causing the vehicle to travel slightly sideways similar to how a dog runs. ● **SEE FIGURE 119–49.**

To check the frame for possible damage, two diagonal measurements of the frame and/or body are required. The diagonal measurements from known points at the front and the rear should be within 1/8 inch (3 mm) of each other.

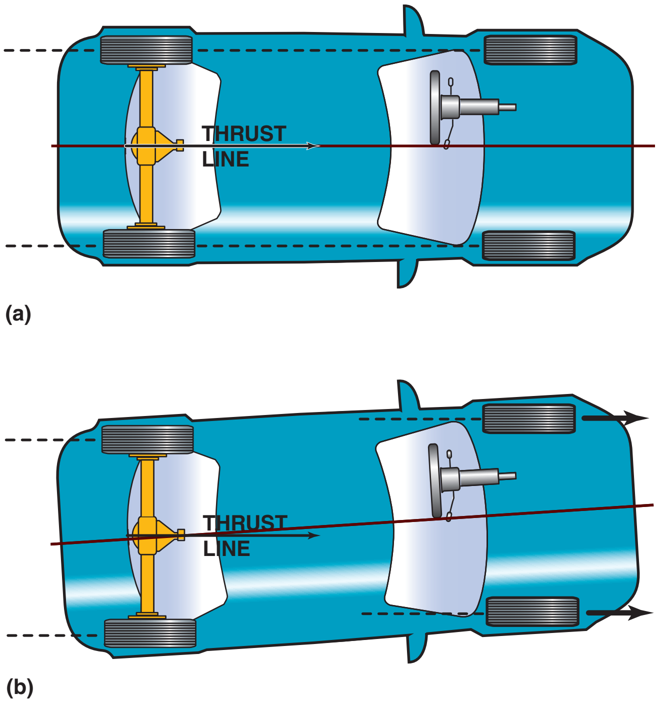

FIGURE 119–49 (a) Proper tracking. (b) Front wheels steering toward thrust line.

FOUR-WHEEL ALIGNMENT

Four-wheel alignment refers to the checking and/or adjustment of all four wheels. Four-wheel alignment is important for proper handling and tire wear. Some rear-wheel-drive vehicles equipped with independent rear suspension can be adjusted for camber and toe. Rear-wheel caster cannot be measured or adjusted because to measure caster, the wheels must be turned from straight ahead. Since rear wheels are securely attached, a caster *sweep* (turning the wheels to take a caster reading) is not possible. While rear camber can cause tire wear problems, by far the greatest tire wear occurs due to toe settings. *Unequal* toe in the rear can cause the vehicle to pull or lead. The rear camber and toe are always adjusted first before adjusting the front caster, camber, and toe. This procedure ensures that the thrust line and centerline of the vehicle are the same.

REVIEW QUESTIONS

1. What are the definitions for camber, caster, and toe?
2. What happens to tire wear and vehicle handling if toe, camber, and caster are out of specification or not equal side to side?
3. Why can knowing SAI, TOOT, and included angle help in the correct diagnosis of an alignment problem?
4. What does thrust angle mean?
5. How does SAI cause the vehicle to straighten the front tires after a turn?

CHAPTER QUIZ

ALIGNMENT DIAGNOSIS AND SERVICE

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Explain the purpose of an alignment and discuss the various checks that should be performed before aligning a vehicle.
- Explain the diagnosis of lead/pull.
- Explain the diagnosis of memory steer.
- Explain the diagnosis of torque steer.
- Describe alignment specifications.
- Describe alignment setup procedures.
- Discuss how to measure camber, caster, SAI, toe, and TOOT.
- Explain diagnostic angles.
- List the types of alignments.
- Discuss rear wheel adjustments.
- Describe how to adjust front camber/caster.
- Discuss setting toe.
- Discuss centering the steering wheel.
- Discuss the tolerance adjustment procedure.
- Explain how to reset the steering angle sensor (SAS).

ALIGNMENT PURPOSE AND PREALIGNMENT

PURPOSE OF AN ALIGNMENT Proper wheel alignment of all four wheels is important for the safe handling of any vehicle. When all four wheels are traveling the same path and/or being kept nearly vertical, tire life and fuel economy are maximized and vehicle handling is sure and predictable. A complete wheel alignment is a complex process that includes many detailed steps and the skill of a highly trained technician.

PREALIGNMENT CORRECTION TECHNIQUES There are four basic steps in the correction of any problem:

1. **Verify.** What, when, where, and to what extent does the problem occur?
2. **Isolate.** Eliminate known good parts and systems. Always start with the simple things first. For example, checking and correcting tire pressure and rotation of the tires should be one of the first things performed whenever trying to isolate the cause of an alignment-related problem.
3. **Repair the problem.** This step involves replacing any worn or damaged components and making sure that the alignment is within factory specifications. ● **SEE FIGURE 120–1.**

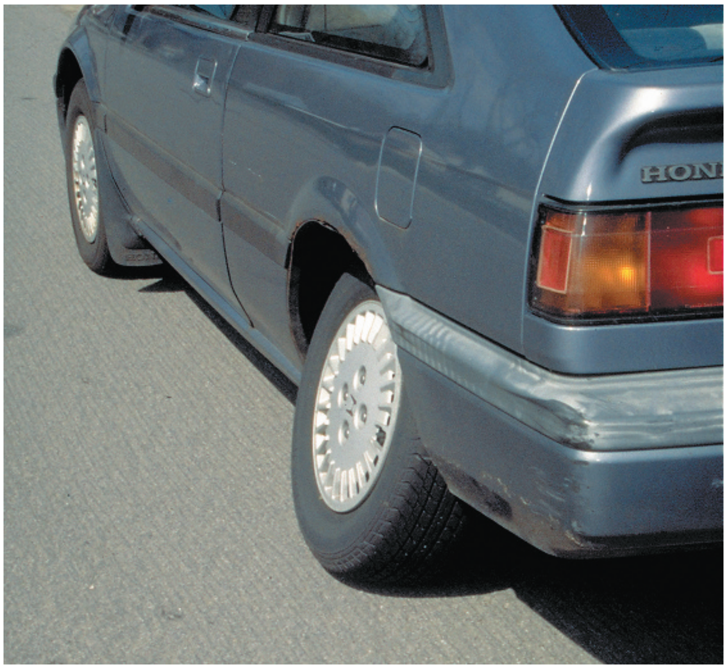

FIGURE 120–1 The owner of this Honda thought that all it needed was an alignment. Obviously, something more serious than an alignment caused this left rear wheel to angle inward at the top.

TECH TIP

Align and Replace at the Same Time

Magnetic bubble-type camber/caster gauges can be mounted directly on the hub or on an adapter attached to the wheel or spindle nut on front-wheel-drive vehicles. ● **SEE FIGURE 120–2**. Besides being used as an alignment setting tool, a magnetic alignment head is a great tool to use whenever replacing suspension components.

Any time a suspension component is replaced, the wheel alignment should be checked and corrected as necessary. An easy way to avoid having to make many adjustments is to use a magnetic alignment head on the front wheels to check camber with the vehicle hoisted in the air *before* replacing front components, such as new MacPherson struts. Then, before tightening all of the fasteners, check the front camber readings again to make sure they match the original setting. This is best done when the vehicle is still off the ground. For example, a typical front-wheel-drive vehicle with a MacPherson strut suspension may have a camber reading of +1/4 degree on the ground and +2 degrees while on the hoist with the wheels off the ground. After replacing the struts, simply return the camber reading to +2 degrees and it should return to the same +1/4 degree when lowered to the ground.

Though checking and adjusting camber before and after suspension service work does not guarantee a proper alignment, it does permit the vehicle to be moved around with the alignment fairly accurate until a final alignment can be performed.

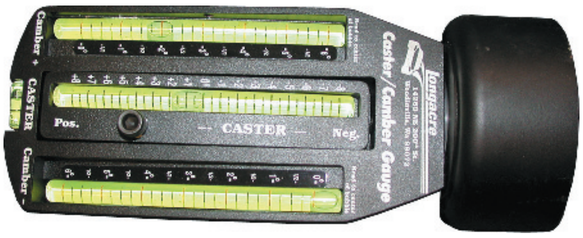

FIGURE 120–2 Magnetic bubble-type camber/caster gauge. To help it keep its strong magnetism, it is best to keep it stored stuck to a metal plate or metal tool box.

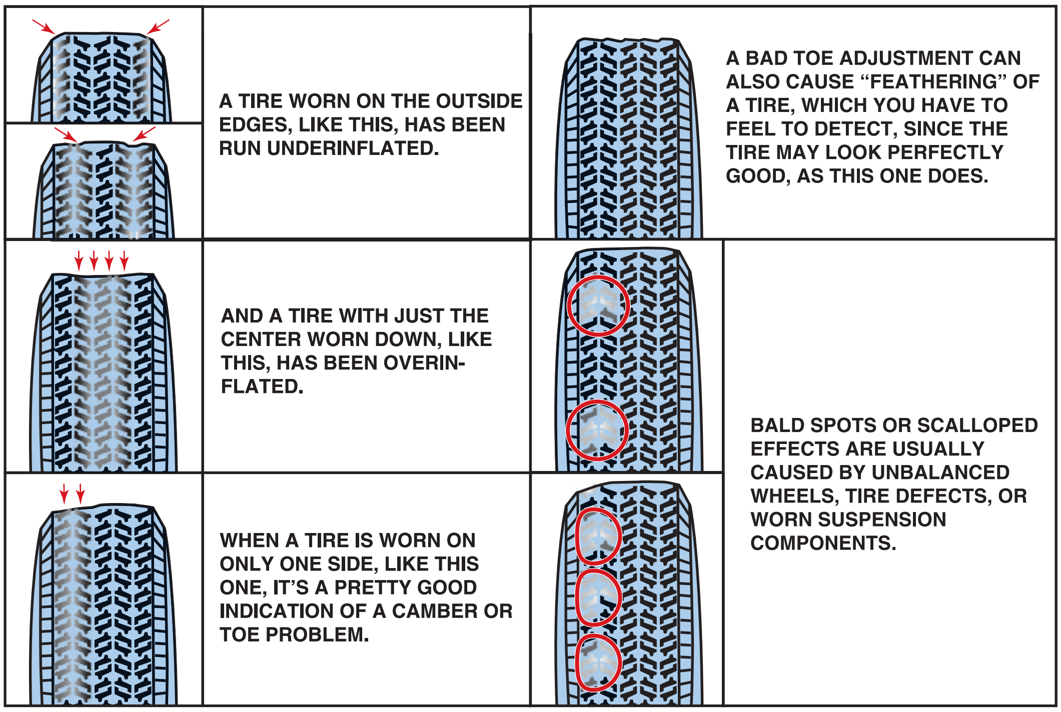
4. **Recheck**. *Always* test-drive the vehicle after making a repair. Never allow the customer to be the first to drive the vehicle after any service work.

A thorough inspection of the steering, suspension, and tires should be performed *before* the alignment of the vehicle is begun.

PREALIGNMENT CHECKS Before checking or adjusting the front-end alignment, the following items should be checked and corrected, if necessary, as part of the **prealignment checks**:

1. Check all the tires for proper inflation pressures. Tires should be approximately the same size and tread depth, and the recommended size for the vehicle. ● **SEE FIGURE 120–3**.
2. Check the wheel bearings for proper adjustment.

NOTE: Some alignment technicians think that the vehicle must have new tires installed before an accurate alignment can be performed. Excessively worn tires, especially if only one tire is worn, can cause the vehicle to lean slightly. It is this unequal ride height that is the important fact to consider. If, for example, all four tires are equally worn, then the vehicle *can* be properly aligned. (Obviously, excessively worn



A TIRE WORN ON THE OUTSIDE EDGES, LIKE THIS, HAS BEEN RUN UNDERINFLATED.

AND A TIRE WITH JUST THE CENTER WORN DOWN, LIKE THIS, HAS BEEN OVERINFLATED.

WHEN A TIRE IS WORN ON ONLY ONE SIDE, LIKE THIS ONE, IT'S A PRETTY GOOD INDICATION OF A CAMBER OR TOE PROBLEM.

A BAD TOE ADJUSTMENT CAN ALSO CAUSE "FEATHERING" OF A TIRE, WHICH YOU HAVE TO FEEL TO DETECT, SINCE THE TIRE MAY LOOK PERFECTLY GOOD, AS THIS ONE DOES.

BALD SPOTS OR SCALLOPED EFFECTS ARE USUALLY CAUSED BY UNBALANCED WHEELS, TIRE DEFECTS, OR WORN SUSPENSION COMPONENTS.

FIGURE 120–3 Typical tire wear chart as found in a service manual. Abnormal tire wear usually indicates a fault in a steering or suspension component that should be corrected or replaced before an alignment is performed.

tires should be replaced, and it would be best to align the vehicle with the replacement tires installed to be assured of an accurate alignment.)

3. Check for loose ball joints or torn ball joint boots.
4. Check the tie rod ends for damage or looseness.
5. Check the center link or rack bushings for play.
6. Check the pitman arm for any movement.
7. Check for runout of the wheels and the tires.
8. Check for vehicle ride height (should be level front to back as well as side to side). Make sure that the factory load-leveling system is functioning correctly, if the vehicle is so equipped. Check height according to the manufacturer's specifications. ● **SEE FIGURES 120–4 AND 120–5**.

NOTE: Manufacturers often have replacement springs or spring spacers that can be installed between the coil spring and the spring seat to restore proper ride level.

9. Check for steering gear looseness at the frame.
10. Check for improperly operating shock absorbers.
11. Check for worn control arm bushings.
12. Check for loose or missing stabilizer bar attachments.

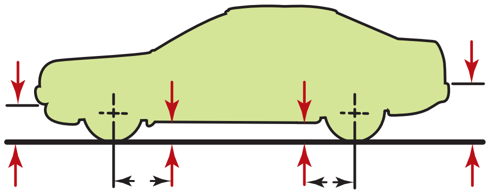


FIGURE 120–4 Measuring points for ride (trim) height vary by manufacturer.

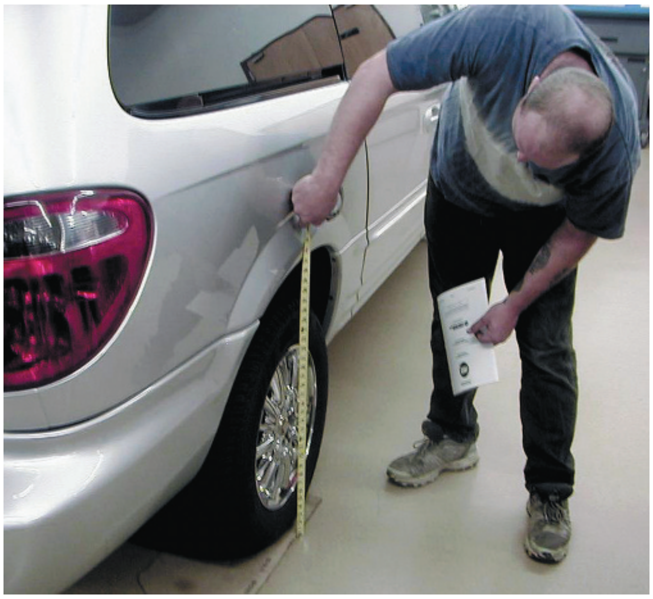

FIGURE 120–5 Measuring to be sure the left and right sides of the vehicle are of equal height. If this measurement is not equal side to side by as little as 1/8 inch (3 mm), it can affect the handling of the vehicle.

13. Check the trunk for excess loads.
14. Check for dragging brakes.

NOTE: Checking for dragging brakes is usually performed when installing alignment heads to the wheels prior to taking an alignment reading. A brake dragging can cause the vehicle to pull or lead toward the side with the dragging brake.

LEAD/PULL

DIAGNOSIS Many alignment requests come from customers attempting to have a lead or pull condition corrected. Before aligning the vehicle, verify the customer complaint first, then perform a careful inspection.

1. Inspect all tires for proper inflation. Both tires on the same axle (front and rear) should be the same size and brand. A lead/pull problem could be due to a defect or condition in one or more of the tires, as shown in ● **FIGURE 120–6**. Before attempting to correct the lead/pull condition by changing alignment angles, try rotating the tires front to back or side to side.
2. Road test the vehicle on a straight, level road away from traffic, if possible. Bring the vehicle to about 40 MPH (65 km/h), shift into neutral, and feel for a pull in the steering, either to the left or to the right. A lead or drift is less severe than a pull, and may occur only if you momentarily remove your hands from the steering wheel while driving.
3. If the lead/pull problem is sometimes toward the left and other times toward the right, check for a **memory steer** condition. If the lead/pull problem occurs during acceleration and deceleration, check for a **torque steer** condition.

MEMORY STEER

DIAGNOSIS **Memory steer** is a term used to describe the lead or pull of a vehicle caused by faults in the steering or suspension system. Often a defective upper strut bearing or steering gear can cause a pulling condition in one direction after making a turn in

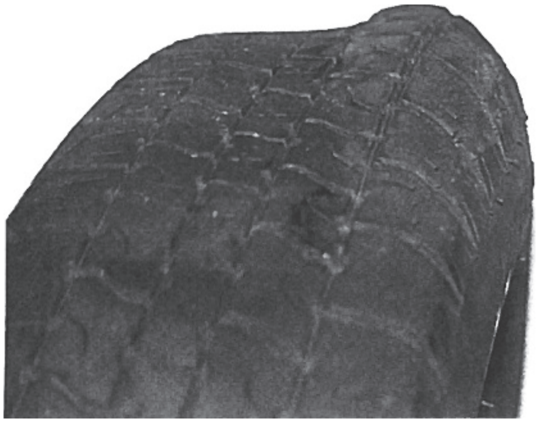

FIGURE 120–6 The bulge in this tire was not noticed until it was removed from the vehicle as part of a routine brake inspection. After replacing this tire, the vehicle stopped pulling and vibrating.

the same direction. It is as if the vehicle had a memory and pulled in the same direction. To test for memory steer, follow these simple steps during a test-drive:

1. With the vehicle stopped at an intersection or in a parking area, turn the steering wheel completely to the left stop and then straighten the wheel without going past the straight-ahead position.
2. Lightly accelerate the vehicle and note any tendency of the vehicle to lead or pull toward the left.
3. Repeat the procedure, turning the steering wheel to the right.

If the vehicle first pulls to the left, then pulls to the right, the vehicle has a memory steer condition.

CORRECTION A binding suspension or **steering component** is the most likely cause of memory steer. Disconnect each wheel from its tie rod end and check for free rotation of movement of each wheel. Each front wheel should rotate easily without binding or roughness. Repair or replace components as necessary to eliminate the binding condition.

NOTE: One of the most common causes of memory steer is the installation of steering or suspension components while the front wheels are turned. Most steering and suspension parts contain rubber, which has a memory if moved from its installed position. If the memory steer condition is only in one direction, then this is the most likely cause. The rubber component exerts a force on the suspension or steering that causes the vehicle to pull toward the side that the wheels were turned toward when the part was installed.

TORQUE STEER

DIAGNOSIS Torque steer occurs in front-wheel-drive vehicles when engine torque causes a front wheel to change its angle from straight ahead. ● **SEE FIGURE 120–7**. This resulting pulling effect is most noticeable during rapid acceleration, especially whenever upshifting of the transmission creates a sudden change in torque being applied to the front wheels. When turning and accelerating at the same time, torque steer has a tendency to straighten the vehicle, so more steering effort may be required to make the turn. Then, if the accelerator is released, a reversing force is applied to the front wheels. Now the driver must take corrective steering motions to counteract the change in steering effect of engine torque.

Torque steer sequence of events

Torque to wheel	a toe-in condition
More torque	more toe-in
Unequal torque	unequal toe-in
Unequal driveshaft angles	unequal torque to the wheels

Most manufacturers try to reduce torque steer in the design of their vehicles by keeping drive axle angles low and equal side to side. If the engine and transaxle are level and the drive axle shafts are kept level, then the torque from the engine will be divided equally between the front wheels.

CORRECTION The service technician cannot change the design of a vehicle, but the technician can, and should, check and correct problems that often cause torque steer. **Check to be sure that the condition is not normal**. It is normal for front-wheel-drive vehicles to exert a tug on the steering wheel and steer toward one side (usually to the right) during acceleration. This is especially noticeable when the transmission shifts from first to second gear under heavy acceleration. To determine how severe the problem is, place a strip of masking tape at the top of the steering wheel. Drive the vehicle and observe the amount of movement required to steer the vehicle straight during heavy acceleration. Repeat the test with a vehicle of similar make and model. If the torque steer is excessive, determine and correct the cause by carefully following the prealignment inspection steps and checking for a level powertrain.

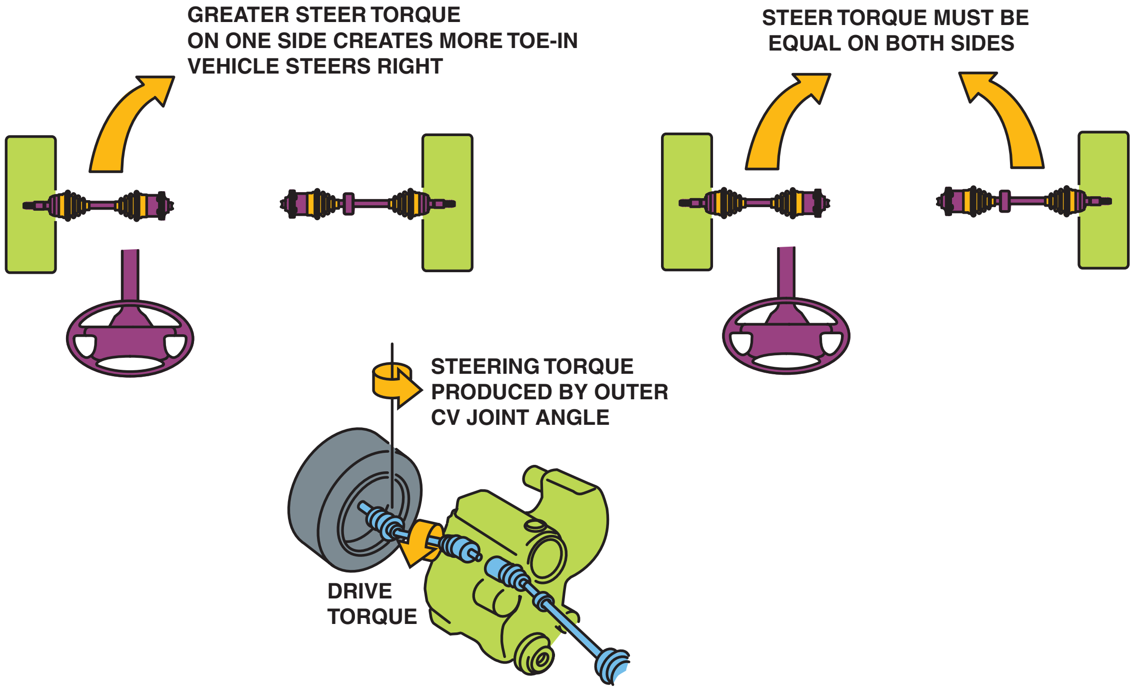

FIGURE 120–7 Equal outer CV joint angles produce equal steer torque (toe-in). If one side receives more engine torque, that side creates more toe-in and the result is a pull toward one side, especially during acceleration.

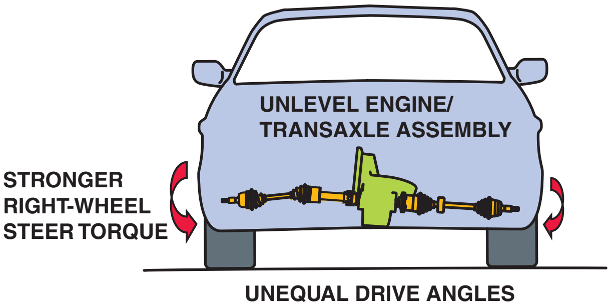

FIGURE 120–8 Broken or defective engine or transaxle mounts can cause the powertrain to sag, causing unequal drive axle shaft CV joint angles.

A defective engine mount can cause the entire drivetrain to sag on one end. If the engine and transaxle of any front-wheel-drive vehicle is not level, the drive axle shaft angles will not be equal, as shown in ● **FIGURE 120–8**.

Hold a straightedge along the engine's supporting frame and measure up to points along the transaxle pan rail or the drive axle shaft. Side-to-side distances should be equal. Standard alignment shims can be used to shim the mounts and level the drivetrain.

CASE STUDY

The Five-Wheel Alignment

The steering wheel should always be straight when driving on a straight, level road. If the steering wheel is not straight, the customer will often think that the wheel alignment is not correct. One such customer complained that the vehicle pulled to the right while driving on a straight road. The service manager test-drove the vehicle and everything was perfect, except that the steering wheel was not perfectly straight, even though the toe setting was correct. Whenever driving on a straight road, the customer would "straighten the steering wheel" and, of course, the vehicle went to one side. After adjusting toe with the steering wheel straight, the customer and the service manager were both satisfied. The technician learned that regardless of how accurate the alignment, the steering wheel must be straight; it is the "fifth wheel" that the customer notices most. Therefore, a **five-wheel alignment** rule includes a check of the steering wheel.

NOTE: Many vehicle manufactures now include the maximum allowable steering wheel angle variation from straight. This specification is commonly ±3 degrees (plus or minus 3 degrees) or less.

Summary:

Complaint—Owner complained that the vehicle pulled to one side after an alignment.
Cause—The steering wheel was not perfectly straight and when the driver straightened the wheel, it went to one side.
Correction—The technician straightened the steering using the tie rod end ends while maintaining the specified toe setting.

If torque steer is still excessive, check all alignment angles, including SAI and included angle. Unequal alignment angles can cause a pull or a lead condition. SAI and included angle should be within 1/2 (0.5) degree side to side for best results. A vehicle will tend to pull toward the side with the least SAI.

ALIGNMENT SPECIFICATIONS

Before attempting any alignment, consider the following:

1. Determine the make, model, and year of the vehicle.
2. Determine if the vehicle is equipped with power steering or manual steering. (Some older models use lower caster specifications for manual steering to reduce steering effort.)
3. Check the trunk and with the customer to determine the normal load being carried. Sometimes customers take out heavy things they normally carry or have something in the vehicle now that they normally do not carry.
4. Determine the correct specifications (if possible, check the specifications from two different sources to ensure correct readings).
5. Compensate for the lack of a full gas tank by placing an equal amount of weight in the luggage compartment. (Gasoline weighs 6 pounds per gallon [0.7 kg per l]—a 20 gallon gas tank, when full, weighs 120 pounds [80 liters weighs 54 kg].)
6. Determine the correct specifications for the *exact* vehicle being checked.

NOTE: Some alignment specifications are published as guidelines for acceptable values for state or local vehicle inspections. Be sure to use the *service* or *set to* specifications.

READING ALIGNMENT SPECIFICATIONS There are several methods used by vehicle manufacturers and alignment equipment manufacturers to specify alignment angles.

MAXIMUM/MINIMUM/PREFERRED METHOD This method indicates the preferred setting for each alignment angle and the minimum

TECH TIP

Keep the Doors Closed, but the Window Down

An experienced alignment technician became upset when a beginning technician opened the driver's door to lock the steering wheel in a straight-ahead position on the vehicle being aligned. The weight of the open door caused the vehicle to sag. This disturbed the level position of the vehicle and changed all the alignment angles.

The beginning technician learned an important lesson that day: Keep the window down on the driver's door so that the steering wheel and brakes can be locked without disturbing the vehicle weight balance by opening a door. The brake pedal must be locked with a pedal depressor to prevent the wheels from rolling as the wheels are turned during a caster sweep. The steering must be locked in the straight-ahead position when adjusting toe.

FIGURE 120–9 This alignment chart indicates the preferred setting with a plus or minus tolerance.

and maximum allowable value for each. The alignment technician should always attempt to align the vehicle to the preferred setting.

PLUS OR MINUS METHOD This method indicates the preferred setting with the lowest and highest allowable value indicated by a negative (−) and positive (+) sign, as in ● **FIGURE 120–9**. For example, if a camber reading is specified as +1/2 degree with a + and − value of 1/2 degree, it could be written as +1/2 degree ±1/2 degree. The minimum value would be 0 degrees (1/2° − 1/2° = 0°) and the maximum value would be +1 degree (+1/2° + 1/2° = 1°). The range would be from 0 to 1 degree.

NOTE: The angle is assumed positive unless labeled with a negative (−) sign in front of the number.

DEGREES, MINUTES, AND FRACTIONS

Specifications are often published in **fractional** or decimal **degrees**, or in degrees and **minutes**. There are 60 minutes (written as 60′) in 1 degree. ● **SEE CHART 120–1.**

To help visualize the amount of these various units, think of decimal degrees as representing money or cents (100 cents = 1 dollar).

0.75 = 75 cents, or 3/4 of a dollar

Minutes can be visualized as minutes in an hour (60' = 1 hour).

45′ = 3/4 of an hour

Now which is larger, 35 minutes or 0.40 degree? The larger angle is 35 minutes because this is slightly greater than 1/2 degree, whereas 0.40 minute is less than 1/2 degree.

FINDING THE MIDPOINT OF SPECIFICATIONS

Many manufacturers specify alignment angles within a range. If you are using equipment that requires a midpoint to be entered, use the following method to determine easily the midpoint of specifications.

FRACTIONS	DECIMAL DEGREES	MINUTES–SECONDS
1/4°	0.25°	0°15′
1/2°	0.50°	0°30′
3/4°	0.75°	0°45′
1°	1.0°	1° or 60′

CHART 120–1

Conversion chart for switching from fractional inches to decimal degrees or minutes and seconds.

Example 1:

Specification: 55′ to 2°25′

STEP 1 The first step is to determine the specification range or span, which is the total angle value from lowest to highest:

2° 25′
−55′
1°30′ Specification range

STEP 2 Dividing the specification range by 2 will give the midpoint of the range:

$$\frac{1^\circ 30'}{2} = \frac{90'}{2'} = 45'$$

STEP 3 To find the midpoint of the specifications, add the midpoint of the range to the smaller specification (or subtract from the larger specification):

45′ midpoint of range
+55′ lowest specification
1°40′ midpoint of specification

Example 2:

Specification: −0.5° to +0.80°

STEP 1 The total range of the specification is determined by adding 0.5 (1 / 2) to 0.80, totalling 1.30°.

NOTE: Since the lower specification is a negative number, we had to *add* the 0.5 degree to bring the lower range of the specification to zero. Then the total is simply the upper range specification added to the number required to bring the lower end of the range to zero.

STEP 2 Dividing the specification range by 2 gives the midpoint of the range:

$$\frac{1.30^\circ}{2} = 0.65^\circ$$

STEP 3 To find the midpoint of the specification, add the midpoint of the range to the smaller specification:

0.65° midpoint of range
+ (0.50°) lowest specification
+ 0.15° midpoint of specification

ALIGNMENT SETUP PROCEDURES

After confirming that the tires and all steering and suspension components are serviceable, the vehicle is ready for an alignment. Setup procedures for the equipment being used must always be followed. Typical alignment procedures include the following:

STEP 1 Drive onto the alignment rack straight and adjust the ramps and/or turn plates so that they are centered under the tires of the vehicle. ● **SEE FIGURE 120–10**.

STEP 2 Use chocks for the wheels to keep the vehicle from rolling off the alignment rack.

STEP 3 Attach and calibrate the wheel sensors to each wheel as specified by the alignment equipment manufacturer. ● **SEE FIGURE 120–11**. The calibration procedure is required whenever the head of the machine is attached to the wheel of the vehicle. All alignment angles and measurements are taken from the readings of the wheel sensors.

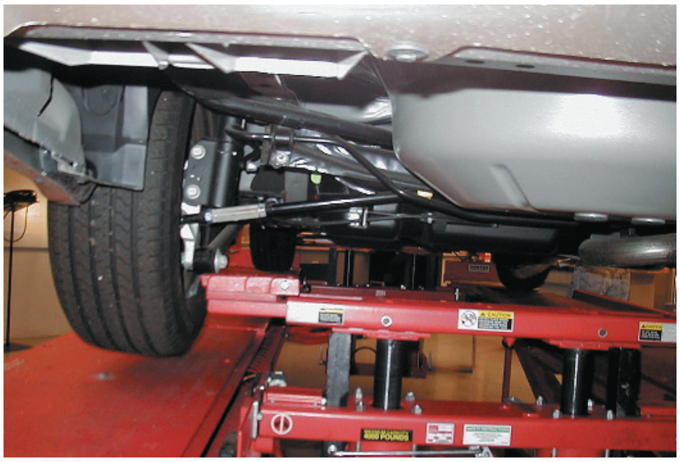

FIGURE 120–10 Using the alignment rack hydraulic jacks, raise the tires off the rack so that they can be rotated as part of the compensating process.

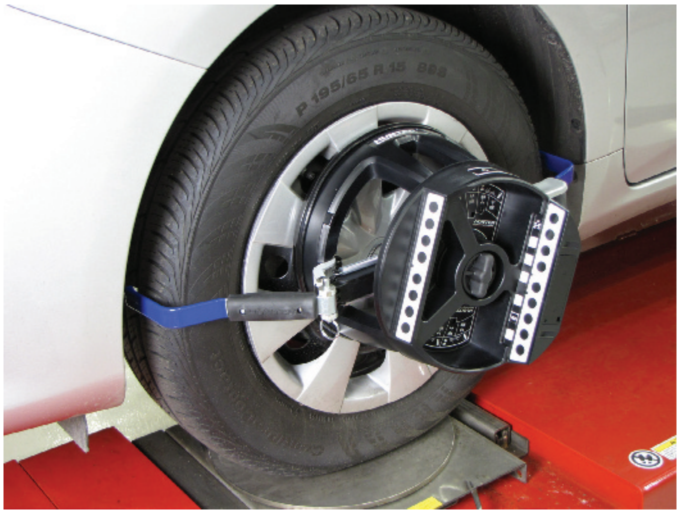

FIGURE 120–11 An optical-type wheel sensor. Compensation is achieved by simply rolling the vehicle backward and forward.

Calibration of these wheel sensors is needed for two reasons:

a. **The wheel may be bent.** If the wheel (rim) is bent, even slightly, this small amount of tilt would be read as an angle of the suspension.

NOTE: Compensating or calibrating the wheel sensor for a bent wheel does *not* correct (or repair) the bent wheel! The bent wheel is still present and can result in a shimmy-type vibration.

b. **The sensors may not be identically installed on the wheel.** Most sensors use three or four wheel-mounting locations. It is not possible to install all wheel sensors perfectly at the same depth on the wheel in all locations. If a sensor must be removed during the alignment process and reinstalled, it should be recalibrated. Always follow the manufacturer's recommended procedure for compensating the sensors.

STEP 4 Unlock all rack or turn plates.

STEP 5 Lower the vehicle and jounce the vehicle by pushing down on the front, then rear, bumper. This motion allows the suspension to become centered.

STEP 6 Following the procedures for the alignment equipment, determine all alignment angles.

MEASURING CAMBER, CASTER, SAI, TOE, AND TOOT

CAMBER Camber is measured with the wheels in the straight-ahead position on a level platform. Since camber is a vertical reference angle, alignment equipment reads camber directly.

CASTER Caster is measured by moving the front wheels through an arc inward, then outward, from straight ahead. This necessary movement of the front wheels to measure caster is called *caster sweep*. What the alignment measuring equipment is actually doing is measuring the camber at one wheel sweep and measuring the camber again at the other extreme of the caster sweep. *The caster angle itself is the difference between the two camber readings.*

SAI Steering axis inclination (SAI) is also measured by performing a caster sweep of the front wheels. While this angle can be read at the same time as caster on many alignment machines, most experts recommend that SAI be measured separately from the caster reading. When measuring SAI separately, the usual procedure involves raising the front wheels off the ground and leveling and locking the wheel sensors before performing a caster sweep. The reason for raising the front wheels is to allow the front suspension to extend to its full droop position. When the suspension is extended, the SAI is more accurately determined because the angle itself is expanded.

TOE Toe is determined by measuring the angle of both front and both rear wheels from the straight-ahead (0 degree) position. Most alignment equipment reads the toe angle for each wheel *and* the combined toe angle of both wheels on the same axle. This combined toe is called **total toe**. Toe angle is more accurate than the center-to-center distance, especially if oversize tires are installed on the vehicle. ● **SEE FIGURE 120–12**.

TOOT Toe-out on turns (TOOT) is a diagnostic angle and is normally not measured as part of a regular alignment, but it is recommended to be performed as part of a total alignment check. TOOT is measured by recording the angle of the front wheels as indicated on the alignment machine display or on the front turn plates. ● **SEE FIGURE 120–13**.

If, for example, the inside wheel is turned 20 degrees, then the outside wheel should indicate about 18 degrees on the turn plate. The exact angles are usually specified by the vehicle manufacturer. The turning angle should be checked only after the toe is correctly set. *The turning angle for the wheel on the outside of the turn should not vary more than 1 1/2 degrees from specifications.* For example, if the specification calls for the right wheel to be steered to the turn 20 degrees, the outside wheel should measure 18 degrees. This measurement should be within 1 1/2 degrees (16.5 to 19.5 degrees). If the TOOT is not correct, a bent steering arm is the usual cause. If TOOT is not correct, tire squealing noise is usually noticed while cornering and excessive tire wear may occur.

NOTE: Some front-wheel-drive vehicles use a nonsymmetrical (unequal) turning angle design. This design is found on various makes and models of vehicles to assist in controlling torque steer. The test procedure is the same except that the turning angle specifications include left-wheel and right-wheel angles when turned inward and outward and may be different readings without indicating a problem.

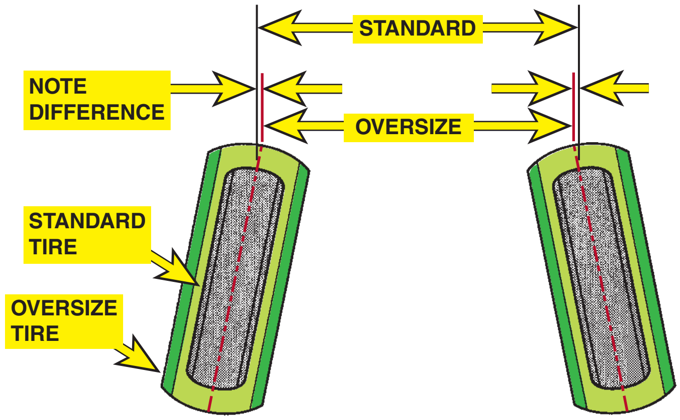

FIGURE 120–12 If toe for an oversize tire is set by distance, the toe angle will be too small. Toe angle is the same regardless of tire size.

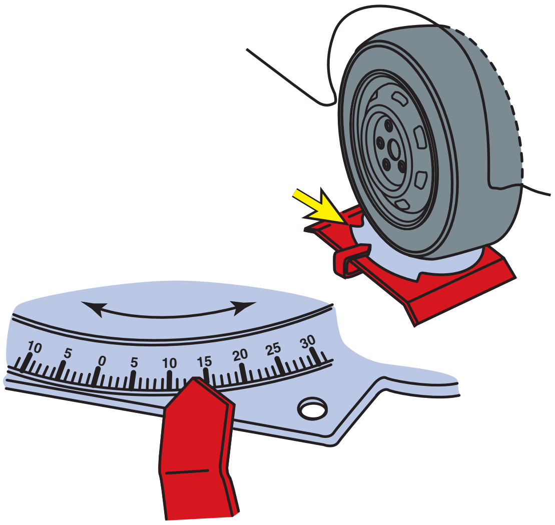

FIGURE 120–13 The protractor scale on the front turn plates allows the technician to test the turning radius by turning one wheel to an angle specified by the manufacturer and observing the angle of the other front wheel. Most newer alignment machines can display turning angle based on sensor readings, and therefore the protractor scale on the turn plate is not needed or used.

DIAGNOSTIC ANGLES

SAI, INCLUDED ANGLE, AND SETBACK Before starting an alignment, the smart technician checks the SAI, included angle, setback, and toe-out on turns to make sure that there is no hidden damage such as a bent spindle or strut that was not found during the prealignment inspection. *Setback is also a diagnostic angle and should be less than 0.5 inch (13 cm or 1/2 degree).* If setback is greater than 0.5 inch (13 cm or 1/2 degree), check the body, frame, and cradle for accident damage or improper alignment.

NOTE: If the SAI or included angle are unequal, suggesting a possible problem such as a bent strut, check the front and rear toe readings. Some alignment equipment cannot show accurate SAI readings if the front or rear toe readings are not within specifications.

CHECKING FOR BENT STRUTS, SPINDLES, OR CONTROL ARMS Even a minor bump against a curb can bend a spindle or a strut housing.

Before attempting to correct an alignment, check all the angles and use the appropriate diagnostic chart to check for hidden damage that a visual inspection may miss.

The chart in ● **FIGURE 120–14** can be used to determine what is wrong if the alignment angles are known. Simply use the chart that correctly identifies the type of suspension on the problem vehicle. The terms used regarding the specifications in ● **FIGURE 120–14** include

- **Correct** The alignment angle is within specifications.
- **Greater than Spec** The alignment angle is greater or higher than specified by the manufacturer.
- **Less than Specs** The alignment angle is less than or lower than specified by the manufacturer.

CHECKING FRAME ALIGNMENT OF FRONT-WHEEL-DRIVE VEHICLES Many front-wheel-drive vehicles mount the drive train (engine and transaxle) and lower suspension arms to a subframe or cradle. If the frame is shifted either left or right, this

TECH TIP

Damage Analysis Tips

To check if a vehicle has been in a collision, technicians should look for the following:

1. Drive the vehicle through a water puddle to see if the tire marks are wider than the tires. If they are, then the front and rear wheels are not tracking correctly.
2. If the setback is out of specifications, then the front of the vehicle may be damaged.
3. If the thrust angle is out of specifications, then rear suspension damage is likely.

TYPES OF ALIGNMENTS

There are three types of alignment: geometric centerline, thrust line, and four-wheel alignment.

GEOMETRIC CENTERLINE Until the 1980s, most wheel alignment concerned only the front wheels. Vehicles, such as sports cars, that had independent rear suspensions were often aligned by backing the vehicle onto the alignment rack and adjusting the rear camber and/or toe. This type of alignment is simply an alignment that uses the **geometric centerline** of the vehicle as the basis for all measurements of toe (front or rear). ● **SEE FIGURE 120–17**.

This method is now considered to be obsolete.

THRUST LINE A **thrust line** alignment uses the thrust angle of the rear wheels and sets the front wheels parallel to the thrust line. ● **SEE FIGURE 120–18**.

An attempt to align this vehicle by adjusting the camber on both sides with either factory or aftermarket kits would result in a totally incorrect alignment.

SUBFRAME CENTERLINE

FIGURE 120–16 This is the same vehicle as shown in *Figure 119–15*, except now the frame (cradle) has been shifted over and correctly positioned. Notice how both the SAI and camber become equal without any other adjustments necessary.

The thrust line is the bisector of rear total toe, or the actual direction in which the rear wheels are pointed. The rear wheels of any vehicle *should* be pointing parallel to the geometric centerline of the vehicle. However, if the rear toe angles of the rear wheels do not total exactly zero (perfectly in a line with the centerline of the vehicle), a thrust condition exists. The front wheels will automatically steer to become parallel to that condition. A crooked steering wheel may also result from an improper thrust condition.

NOTE: It has often been said that while the front wheels steer the vehicle, the rear wheels determine the direction in which the vehicle will travel. Think of the rear wheels as a rudder on a boat. If the rudder is turned, the direction of the boat changes due to the angle change at the rear of the boat.

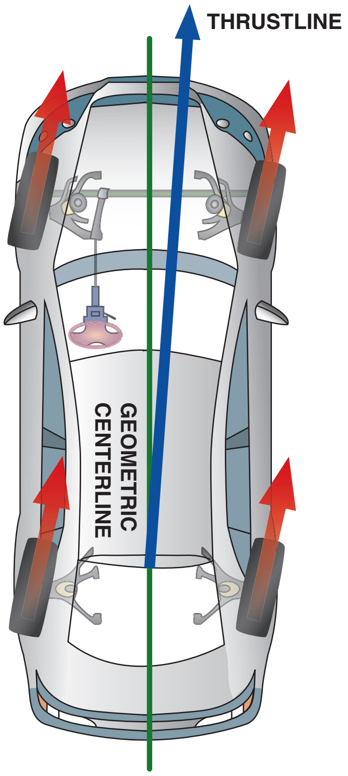
FIGURE 120–17 Geometric-centerline-type alignment sets the front toe readings based on the geometric centerline of the vehicle and does not consider the thrust line of the rear wheel toe angles.



THRUSTLINE
GEOMETRIC CENTERLINE

FIGURE 120–18 Thrust line alignment sets the front toe parallel with the rear-wheel toe.

Thrust line alignment is *required* for any vehicle with a non-adjustable rear suspension. If a vehicle has an adjustable rear suspension, then a four-wheel alignment is necessary to ensure proper tracking.

FOUR-WHEEL ALIGNMENT

A **four-wheel alignment** is the most accurate alignment method and is necessary to ensure maximum tire wear and vehicle handling. The biggest difference between a thrust-line alignment and a four-wheel alignment is that the rear toe is adjusted to bring the thrust line to zero. In other words, the rear toe on both rear wheels is adjusted equally so that the actual direction in which the rear wheels are pointed is the same as the geometric centerline of the vehicle. ● **SEE FIGURE 120–19.**

The procedure for a four-wheel alignment includes these steps:

1. Adjust the rear camber (if applicable).
2. Adjust the rear toe (this should reduce the thrust angle to near zero).
3. Adjust the front camber and caster.
4. Adjust the front toe, being sure that the steering wheel is in the straight-ahead position.
5. Reset the steering angle sensor (if equipped).

SAMPLE ALIGNMENT SPECIFICATIONS AND READINGS

The service technician must know not only all of the alignment angles but also the interrelationship that exists among the angles. As an aid toward understanding these relationships, two examples are presented: Example 1 gives the front wheel angles that are acceptable when compared with the specifications; Example 2 gives four-wheel alignment and readings of a vehicle that are not within specifications.

Example 1: Wheel Alignment

Alignment Specifications

	Left	Right
Camber =	+1/2° ± 1/2°	+1/2° ± 1/2°
Caster =	+1° ± 1/2°	+1° ± 1/2°
Toe (total) =	1/8 in. ± 1/16 in.	

Actual Reading

	Left	Right
Camber =	+1/4°	0°
Caster =	+1°	+1 1/4°
Toe (total) =	1/8 in.	

Answer:

Alignment is perfect:

a. No tire wear

b. No pulling

Explanation:

Camber is within specifications.

Camber is within 1/2 degree difference side to side.

Camber is not equal, but there is more camber on the left (1/4 degree) than on the right, thereby helping to compensate for the road crown.

Caster is within specifications.

Caster is within 1/2 degree difference side to side.

Caster is not equal, but there is more caster on the right (1/4 degree) than on the left, thereby helping (very slightly) to compensate for road crown.

Toe is within specifications.

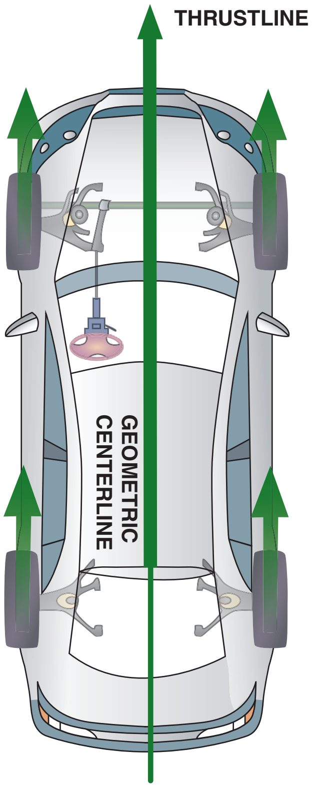


FIGURE 120–19 Four-wheel alignment corrects for any rear-wheel toe to make the thrust line and the geometric centerline of the vehicle both the same.

Example 2: Four-Wheel Alignment

Specifications

	Left	Right
Front camber =	+1/4° ± 1/2°	0° ± 1/2°
Front caster =	+3° ± 1/2°	+3° ± 1/2°
Front toe (total) =	3/16 in. ± 1/16 in.	
Rear camber =	0° ± 1/4°	0° ± 1/4°
Rear toe =	0 in. ± 1/16 in.	

Actual Reading

	Left	Right
Front camber =	−1/2°	−1°
Front caster =	+2 3/4°	+2°
Front toe =	−1/8 in. (toe-out)	
Rear camber =	0°	+1/4°
Rear toe =	1 1/2° (toe-in)	

Answer:

Alignment is incorrect.

a. Left front tire will wear slightly on the inside edge.

b. Right front tire will wear on the inside edge.

c. Vehicle could tend to pull slightly to the left due to the camber difference (may not pull at all due to the pulling effect of the road crown).

d. Vehicle could tend to pull slightly to the right due to the caster difference (3/4 degree more caster on the left).

TECH TIP

Ask Yourself These Three Questions

An older technician told a beginning technician that the key to success in doing a proper alignment is to ask yourself three questions about the alignment angles:

Question 1. **"Is it within specifications?"** For example, if the specification reads 1 degree ±1/2 degree, any reading between +1/2 degree and 1 1/2 degrees is within specifications. All vehicles should be aligned within this range. Individual opinions and experience can assist the technician as to whether the actual setting should be at one extreme or the other or held to the center of the specification range.

Question 2. **"Is it within 1/2 degree of the other side of the vehicle?"** Not only should the alignment be within specifications, but it should also be as equal as possible from one side to the other. The difference between the camber from one side to the other side is called cross-camber. Cross-caster is the difference between the caster angle from one side to another. Some manufacturers and technicians recommend that this side-to-side difference be limited to just 1/4 degree!

Question 3. **"If the camber and caster cannot be exactly equal side to side in the front, is there more camber on the left and more caster on the right to help compensate for road crown?"** Seldom, if ever, are the alignment angles perfectly equal. Sometimes one side of the vehicle is more difficult to adjust than the other side. Regardless of the reasons, if there *has* to be a difference in front camber and/or caster angle, follow this advice to avoid a possible lead or drift problem even if the answers to the first two questions are "yes."

FREQUENTLY ASKED QUESTION

How Does Normal Wear Affect the Alignment Angles?

As a vehicle ages, the springs sag and steering and suspension components wear.

- When springs sag, the ride height changes and the camber usually is reduced and often becomes negative compared to slightly positive when the vehicle was new in most cases.
- When tie rod ends and other steering components wear, the front wheels tend to toe out.
- Worn suspension components can cause excessive play making the vehicle unstable and cause the tires to wear abnormally.

Alignment alone cannot take the place of worn parts. All an alignment can do is try to compensate for the worn parts.

Toe is the most common angle that needs to be adjusted because any wear in the steering or suspension systems affect the toe.

e. Overall pull could be slight toward the left because it requires four times the caster difference to have the same pulling forces as camber.

f. Tires could wear slightly on both the inside edges due to toe-out.

g. The negative camber of the present alignment puts a heavy load on the outer wheel bearing, if RWD, because the load is being carried by the smaller outer wheel bearing instead of the larger inner wheel bearing.

Conclusion:

The vehicle would wear the inside edges of both front tires.
The vehicle may or may not pull slightly to the left.
The vehicle would not act as stable while driving—possible wander.

REAR WHEEL ADJUSTMENTS

ADJUSTING REAR CAMBER Adjusting rear camber is the first step in the four-wheel alignment process. Rear camber is rarely made adjustable, but can be corrected by using aftermarket alignment kits or shims. If rear camber is not correct, vehicle handling and tire life are affected. Before attempting to adjust or correct rear camber, carefully check the body and/or frame of the vehicle for accident damage, including the following:

1. Weak springs, torsion bars, or overloading (check ride height)
2. Bowed rear axle, trailing arm, or rear control arm
3. Suspension mount or body dimension not in proper location
4. Incorrectly adjusted camber from a previous repair

The cause of the incorrect rear camber could be accident-related and the body or frame may have to be pulled into correct position. ● **SEE FIGURES 120–20 THROUGH 120–22** for examples of various methods used to adjust rear camber.

USING PLASTIC OR METAL ALIGNMENT SHIMS Using plastic or metal alignment shims to correct angles in the rear of the vehicle is relatively simple and includes the following steps:

1. Take alignment readings and determine the change needed.
2. Select proper shims using the easy-to-read chart.

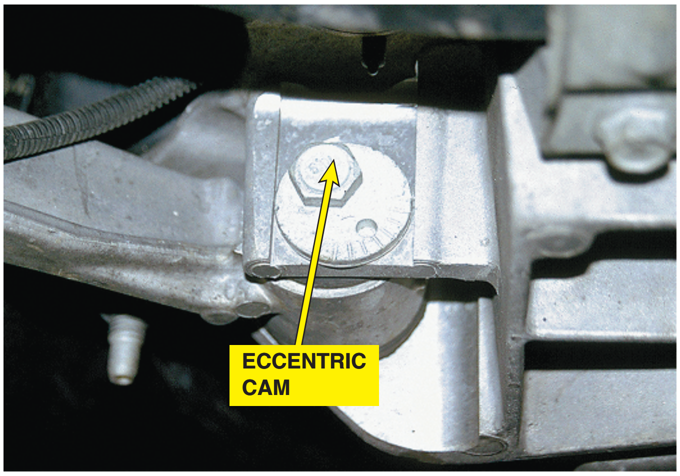

FIGURE 120–20 The rear camber is adjustable on this vehicle by rotating the eccentric cam and watching the alignment machine display.

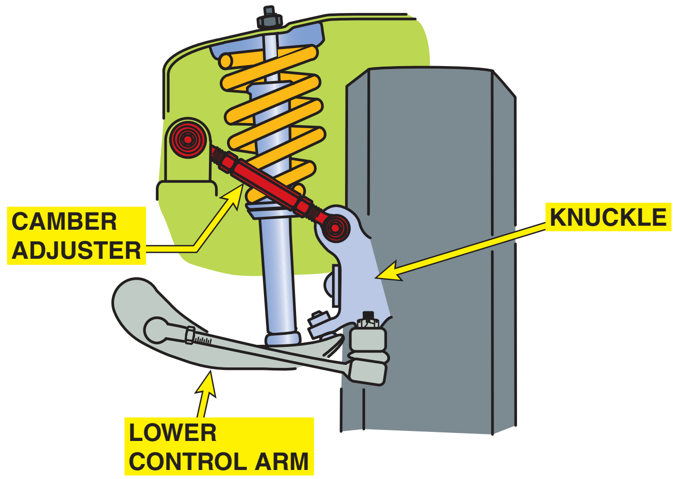

FIGURE 120–21 Some vehicles use a threaded fastener similar to a tie rod to adjust camber on the rear suspension.

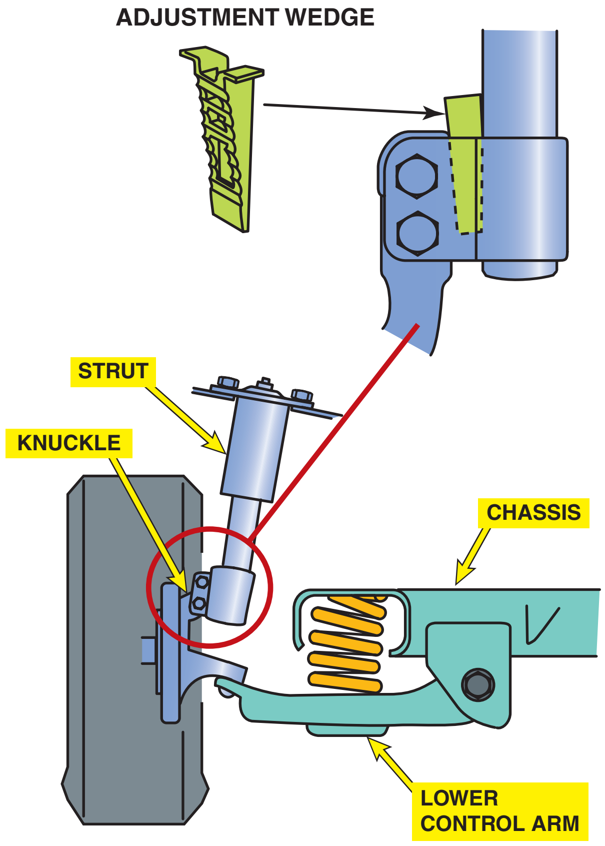

FIGURE 120–22 Aftermarket alignment parts or kits are available to change the rear camber.

TECH TIP

The Gritty Solution

Many times it is difficult to loosen a Torx bolt, especially those used to hold the backing plate onto the rear axle on many GM vehicles. ● **SEE FIGURE 120–23.**

A technique that always seems to work is to place some valve grinding compound on the fastener. The gritty compound keeps the Torx socket from slipping up and out of the fastener, and more force can be exerted to break loose a tight bolt. Valve grinding compound can also be used on Phillips head screws as well as other types of bolts, nuts, and sockets.

3. Using the template provided, mark and remove tabs to create a proper mounting bolt pattern.
4. Install shim.

ADJUSTING REAR TOE Many vehicle manufacturers provide adjustment for rear toe on vehicles that use an independent rear suspension. Rear toe adjusts the thrust angle. A thrust angle that exceeds 1/2 degree (0.5 degree) on a vehicle with a solid axle is an indication that a component may be damaged or out of place in the rear of the vehicle. Rear toe is often adjusted using an adjustable tie rod end or an eccentric cam on the lower control arm. Check a service manual for the exact method for the vehicle being aligned. Most solid rear axles do not have a method to adjust rear toe except for aftermarket shims or kits. ● **SEE FIGURES 120–24 THROUGH 120–26.**

NOTE: On vehicles equipped with four-wheel steering, refer to the service manual for the exact procedure to follow to lock or hold the rear wheels in position for a proper alignment check.

FRONT CAMBER/CASTER ADJUSTMENT METHODS

Many vehicles are constructed with only limited camber/caster factory adjustment. ● **SEE FIGURE 120–27** for a summary of which adjustments are *generally* possible for various types of vehicles and suspension systems.

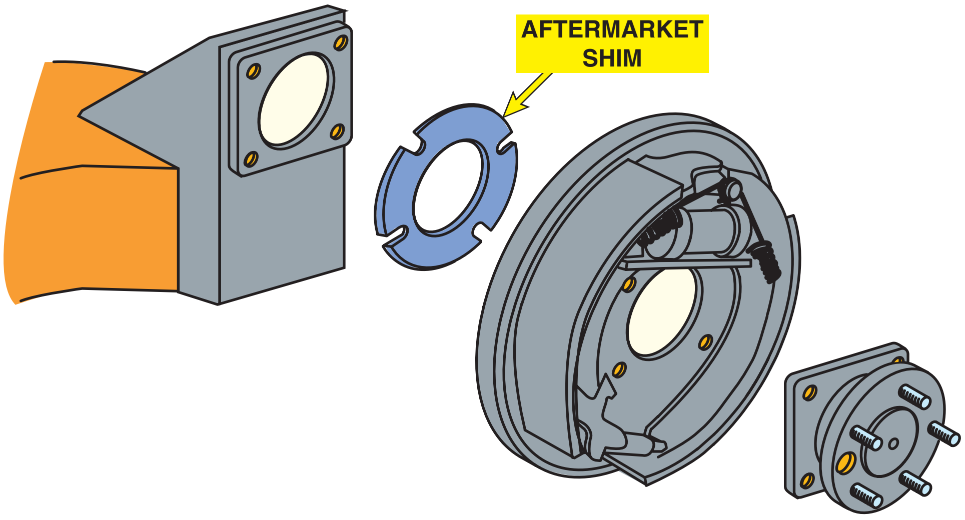

FIGURE 120–23 Full-contact plastic or metal shims can be placed between the axle housing and the brake backing plate to change rear camber, toe, or both.

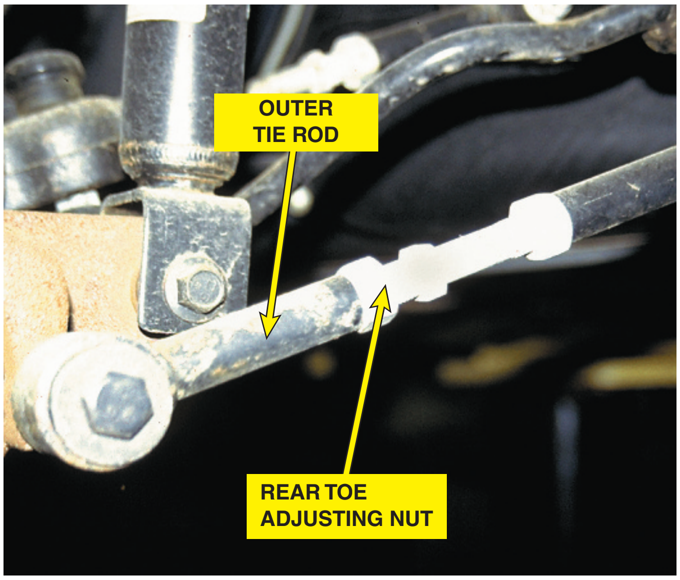

FIGURE 120–24 The rear toe was easily set on this vehicle. The adjusting nuts were easy to get to and turn. Adjusting rear toe is not this easy on every vehicle.

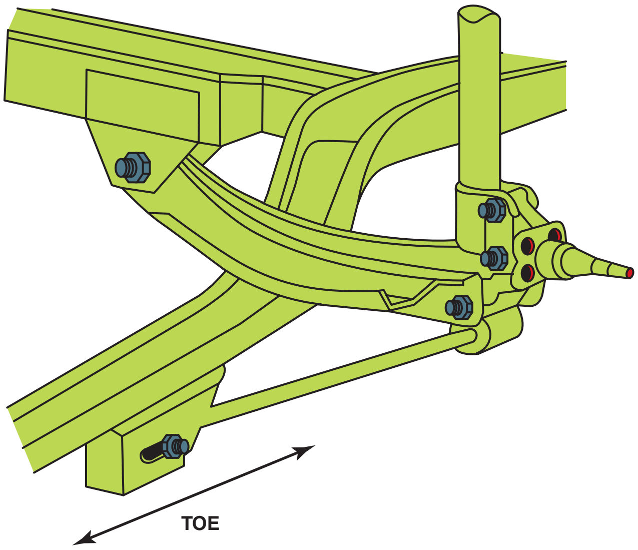

FIGURE 120–25 By moving various rear suspension members, the rear toe can be changed.

CAUTION: Most vehicle manufacturers warn technicians not to adjust camber by bending the strut assembly. Even though several equipment manufacturers make tools that are designed to bend the strut, most experts agree that it can cause harm to the strut itself.

Most SLA-type suspensions can be adjusted for caster and camber. Most manufacturers recommend adjusting caster, then camber, before adjusting the toe. As the caster is changed, such as when the strut rod is adjusted as shown in ● **FIGURE 120–28**, the camber and toe also change.

If the camber is then adjusted, the caster is unaffected. Many technicians adjust caster and camber at the same time using shims (● **SEE FIGURES 120–29 AND 120–30**), slots (● **SEE FIGURE 120–31**), or **eccentric cams** (● **SEE FIGURE 120–32**).

Regardless of the methods or procedures used, toe is always adjusted after all the angles are set because caster and camber both affect the toe. *Always follow the manufacturer's recommended alignment procedure*.

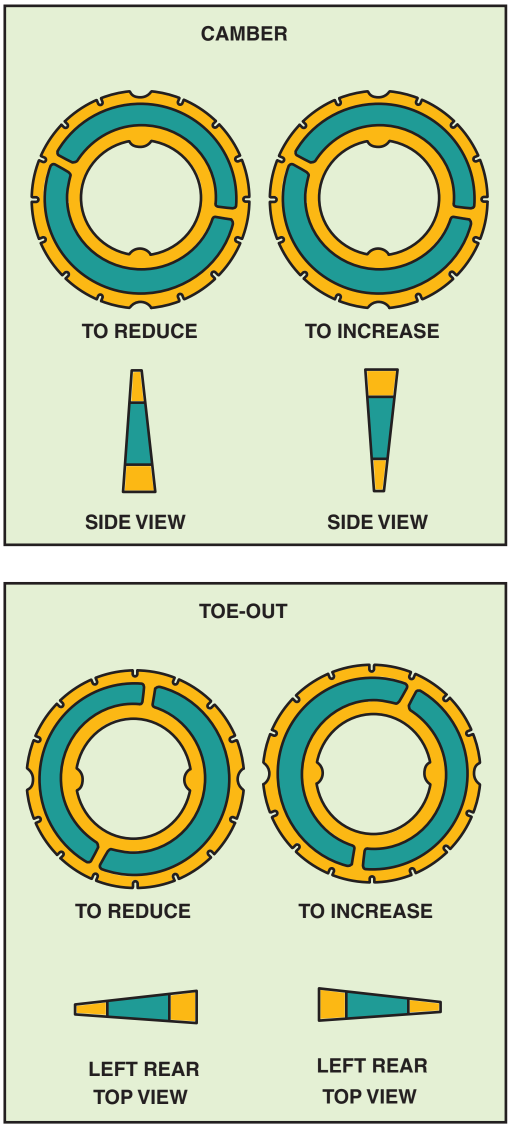

FIGURE 120–26 The use of these plastic or metal shims requires that the rear wheel as well as the hub assembly and/or backing plate be removed. Proper torque during reassembly is critical to avoid damage to the shims.

SETTING TOE

Front toe is the last angle that should be adjusted and is the most likely to need correction. This has led to many sayings in the alignment field:

> "Set the toe and let it go."
>
> "Do a toe and go."
>
> "Set the toe and collect the dough."

As wear occurs at each steering joint such as tie rod ends, the forces exerted on the linkage by the tire tend to cause a toe-out condition.

Front-wheel-drive (FWD) vehicles transmit engine power through the front wheels. Many manufacturers of FWD vehicles specify a toe-out setting. This toe-out setting helps compensate for the slight toe-in effect of the engine torque being transferred through the front wheels.

Most newer alignment equipment displays in degrees of toe instead of inches of toe. (See the toe unit conversion chart.) Just remember that positive (+) toe means toe-in and negative (–) toe means toe-out.

FIGURE 120–30 The general rule of thumb is that a 1/8 inch shim added or removed from both shim locations changes the camber angle about 1/2 degree. Adding or removing a 1/8 inch shim from one shim location changes the caster by about 1/4 degree.

To make sure the steering wheel is straight after setting toe, it *must* be locked in the straight-ahead position while the toe is being adjusted. Another term used to describe steering wheel position is **spoke angle**. To lock the steering wheel, always use a steering wheel lock that presses against the seat and the outer rim of the steering wheel. *Do not* use the locking feature of the steering column to hold the steering wheel straight. Always unlock the steering column, straighten the steering wheel, and install the steering wheel lock. ● **SEE FIGURES 120–33 THROUGH 120–35.**

NOTE: The engine must be started and the steering wheel straightened with the engine running to be assured of a straight steering wheel. Lock the steering wheel with the steering lock tool before stopping the engine.

After straightening the steering wheel, turn the tie rod adjustment until the toe for both wheels is within specifications. ● **SEE FIGURE 120–36.**

CENTERING THE STEERING WHEEL

Centerline steering *should* be accomplished by adjusting the tie rod length on both sides of the vehicle while the toe is set.

FIGURE 120–31 Some SLA-type suspensions use slotted holes for alignment angle adjustments. When the pivot shaft bolts are loosened, the pivot shaft is free to move unless held by special clamps as shown. By turning the threaded portion of the clamps, the camber and caster can be set and checked before tightening the pivot shaft bolts.

CAUTION: Do not attempt to straighten the steering wheel by relocating the wheel on the steering column on a vehicle with two tie rod end adjusters. The steering wheel is positioned at the factory in the center of the steering gear, regardless of type. If the steering wheel is not in the center, then the variable ratio section of the gear will not be in the center as it is designed. Another possible problem with moving the steering wheel from its designed straight-ahead position is that the turning radius may be different for right- and left-hand turns.

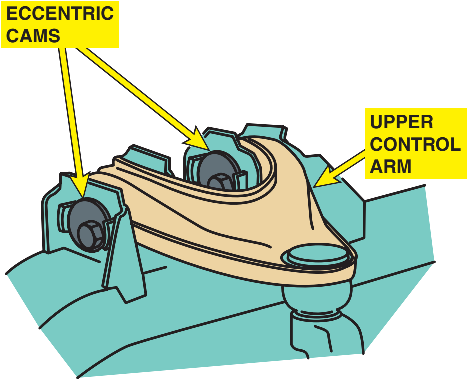

FIGURE 120–32 When the nut is loosened and the bolt on the eccentric cam is rotated, the upper control arm moves in and out. By adjusting both eccentric cams, both camber and caster can be adjusted.

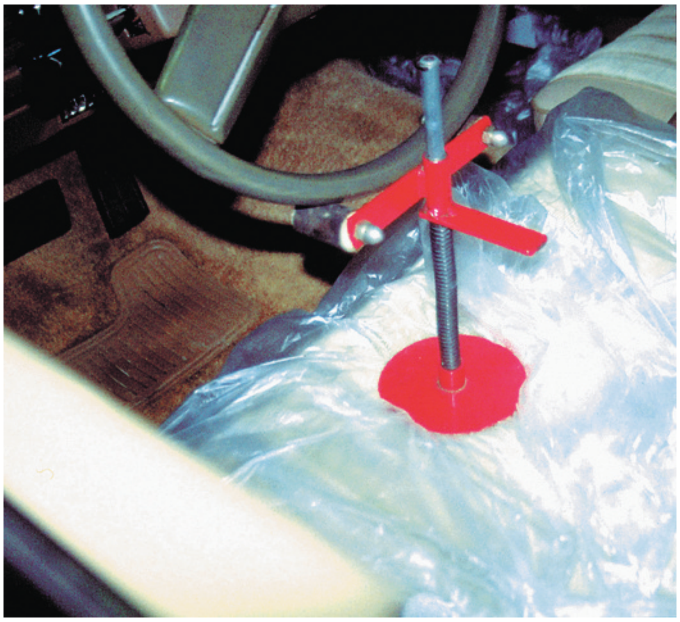

FIGURE 120–33 Many procedures for setting toe specify that the steering wheel be held in the straight-ahead position using a steering wheel lock, as shown. One method recommended by Hunter Engineering sets toe without using a steering wheel lock.

TECH TIP

Autocross Vehicle Alignment

Vehicles used in autocrossing (individual timed runs through cones in a parking lot) or road racing usually perform best if the following alignment steps are followed:

1. **Increase caster (+).** Not only will the caster provide a good solid feel for the driver during high speed on a straight section of the course, but it will also provide some lean into the corners due to the camber change during cornering. A setting of 5 to 9 degrees positive caster is typical depending on the type of vehicle and the type of course.
2. **Adjust for 1 to 2 degrees of negative camber.** As a race vehicle corners, the body and chassis lean. As the chassis leans, the top of the tire also leans outward. By setting the camber to 1 to 2 degrees negative, the tires will be neutral while cornering, thereby having as much rubber contacting the road as possible.

NOTE: Though setting negative camber on a street-driven vehicle will decrease tire life, the negative setting on a race vehicle is used to increase cornering speeds, and tire life is not a primary consideration.

3. **Set toe to a slight toe-out position.** When the front toe is set negative (toe-out), the vehicle is more responsive to steering commands from the driver. With a slight toe-out setting, one wheel is already pointed in the direction of a corner or curve. Set the toe-out to −3/8 to −1/2 degree depending on the type of vehicle and the type of race course.

TOLERANCE ADJUSTMENT PROCEDURE

Many vehicles are designed and built without a method to change caster or camber, or both. (All vehicles have an adjustment for toe.) Before trying an aftermarket alignment correction kit, many technicians first attempt to correct the problem by moving the suspension attachment points within the build tolerance. All vehicles are constructed with a slight amount of leeway or tolerance; slight corrections can be made because bolt holes are almost always slightly larger than the bolt diameter, allowing for slight movement. When several fasteners are involved, such as where the powertrain cradle (subframe) attaches to the body of the front-wheel-drive vehicle, a measurable amount of alignment change (often over 1/2 degree) can be accomplished without special tools or alignment kits. The steps for **tolerance adjustment** include the following:

STEP 1 Determine which way the suspension members have to be moved to accomplish the desired alignment—for example, the right front may require more positive camber to correct a pulling or tire wear problem.

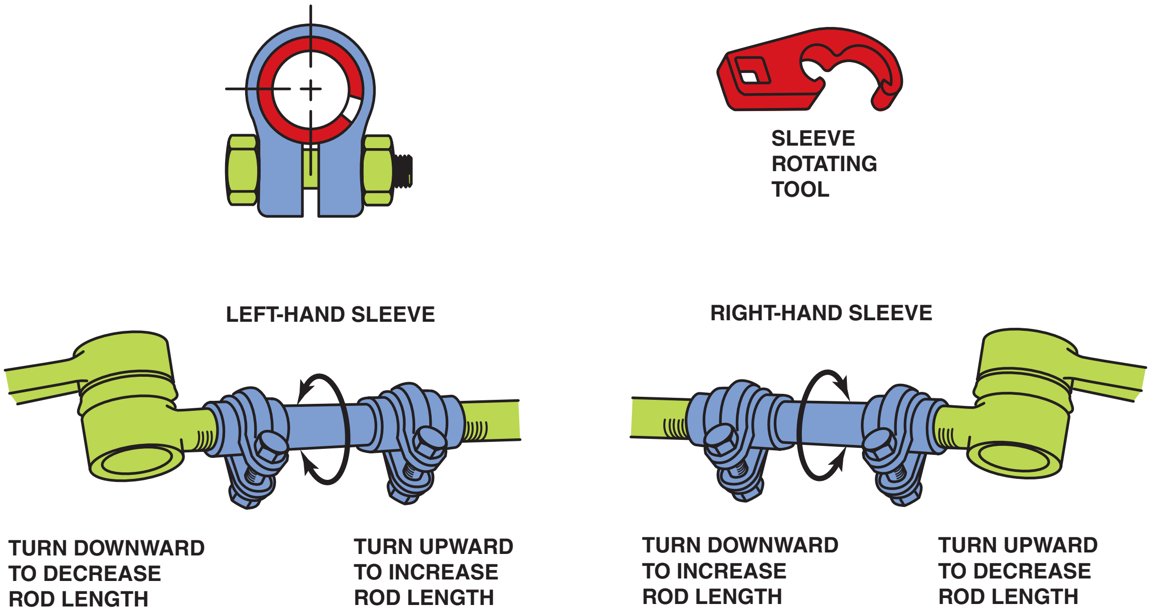

FIGURE 120–35 Toe is adjusted on a parallelogram-type steering linkage by turning adjustable tie rod sleeves. Special tie rod sleeve adjusting tools should be used that grip the slot in the sleeve and will not crush the sleeve while it is being rotated.

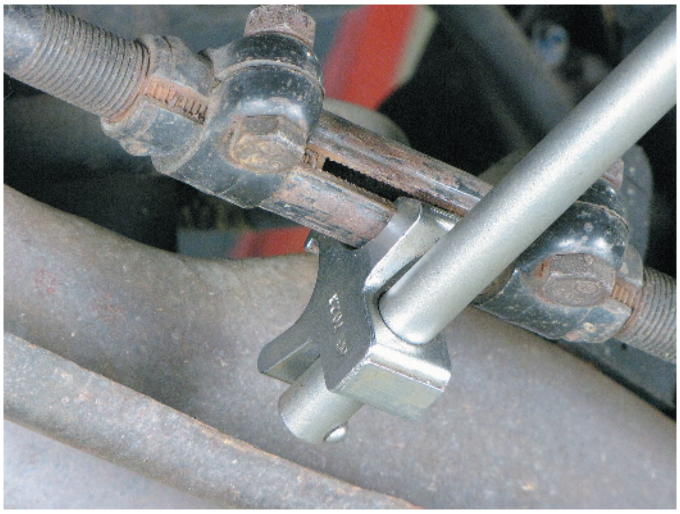

FIGURE 120–36 Special tie rod adjusting tools should be used to rotate the tie rod adjusting sleeves. The tool grips the slot in the sleeve and allows the service technician to rotate the sleeve without squeezing or damaging the sleeve.

STEP 2 Locate and loosen the cradle (subframe) bolts about four turns each. **Do Not Remove Any of the Bolts**.

STEP 3 Using prybars, move the cradle in the direction that will result in an improvement of the alignment angles. Have an assistant tighten the bolts as pressure is maintained on the cradle.

STEP 4 Measure the alignment angles and repeat the procedure if necessary.

AFTERMARKET ALIGNMENT METHODS Accurate alignments are still possible on vehicles without factory methods of adjustment by using alignment kits or parts. Aftermarket alignment kits are available for most vehicles. Even when there are factory alignment methods, sometimes the range of adjustment is not enough to compensate for sagging frame members or other normal or accident-related faults. ● **SEE FIGURES 120–38 AND 120–39**.

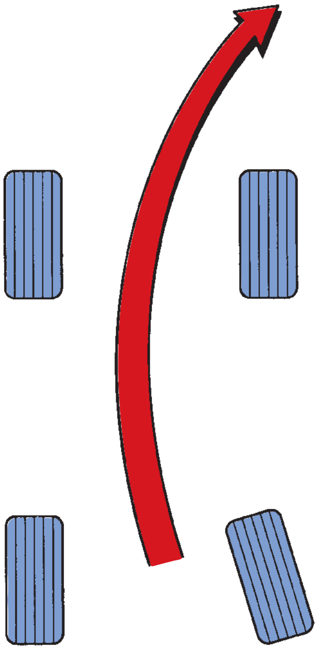

FIGURE 120–37 The toe-in on the right wheel creates a turning force toward the right.

ALIGNING ELECTRONIC-SUSPENSION VEHICLES When aligning a vehicle equipped with an electronic suspension, several additional steps may be required. Always check service information and read carefully all on-screen instructions on the alignment machine. Some examples of the steps that may be needed include

- Verify the exact type of electronic suspension. This step could include checking the regular production order (RPO) code.
- Check that the ride height (suspension height) is within factory specifications.
- The steering wheel angle, as well as the radar cruise control sensor, will often need to be recalibrated using a scan tool. This is needed because the steering wheel may be in

CASE STUDY

Left Thrust Line, but a Pull to the Right!

A new four-door sport sedan had been aligned several times at the dealership in an attempt to solve a pull to the right. The car had front-wheel-drive and four-wheel independent suspension. The dealer rotated the tires, and it made no difference. The alignment angles of all four wheels were in the center of specifications. The dealer even switched all four tires from another car in an attempt to solve the problem.

In frustration, the owner took the car to an alignment shop. Almost immediately the alignment technician discovered that the right rear wheel was slightly toed-in. This caused a pull to the right. ● **SEE FIGURE 120–39**.

The alignment technician adjusted the toe on the right rear wheel and reset the front toe. The car drove beautifully.

The owner was puzzled about why the new car dealer was unable to correct the problem. It was later discovered that the alignment machine at the dealership was out of calibration by the exact amount that the right rear wheel was out of specification. The car pulled to the right because the independent suspension created a rear steering force toward the left that caused the front to pull to the right. Alignment equipment manufacturers recommend that alignment equipment be calibrated regularly.

Summary:

Complaint—Owner complained that the vehicle pulled to the right after an alignment.
Cause—The rear toe on the right was toed in and out of specification.
Correction—The technician adjusted the rear toe on the right rear to factory specifications.

a different position after the alignment, and the steering wheel position sensor needs to be reset because the rear toe setting was changed. The rear thrust line could also have been changed. The radar cruise control needs to be calibrated to the revised rear thrust angle using a scan tool.

RESET STEERING ANGLE SENSOR (SAS)

PURPOSE The **steering angle sensor (SAS)** is usually located at the base of the steering column inside the vehicle and monitors the driver's steering input from straight ahead. It also monitors how fast the driver is turning the wheel and reports this information to body control module (BCM) in most applications. The steering angle sensor is an input to the following systems:

- Electronic stability control (ESC) system
- Electronic power steering (EPS)
- Variable-rate steering (VRS) system
- Antilock brake system (ABS)
- Lane departure warning (LDW) system
- Parking assist (PA) system

ANALOG STEERING ANGLE SENSOR An analog steering angle sensor is similar to a throttle position sensor with a three-wire connector:

- 5 volt reference
- chassis ground
- signal output

As the steering wheel is turned, the SAS produces a signal that varies between 0 and 5 volts as the wheel is turned 360 degrees. Most vehicles produce a positive voltage turning right and a negative voltage turning left. ● **SEE FIGURE 120–40**.

DIGITAL STEERING ANGLE SENSOR A digital SAS often uses LED light and a notched wheel that acts as a shutter with an optic

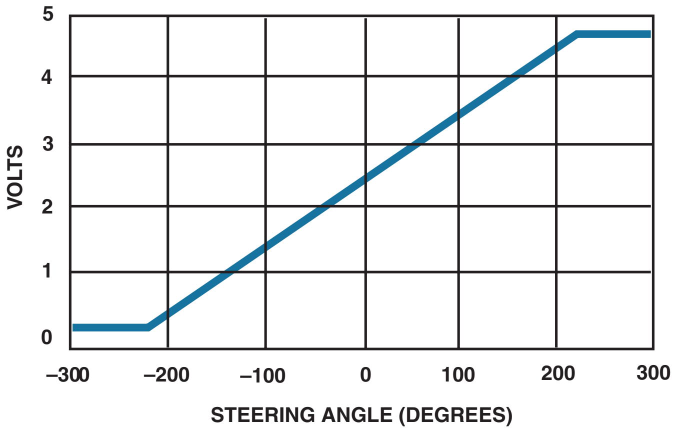

FIGURE 120–40 A typical analog-type steering angle sensor that uses a variable voltage as the steering wheel is rotated.

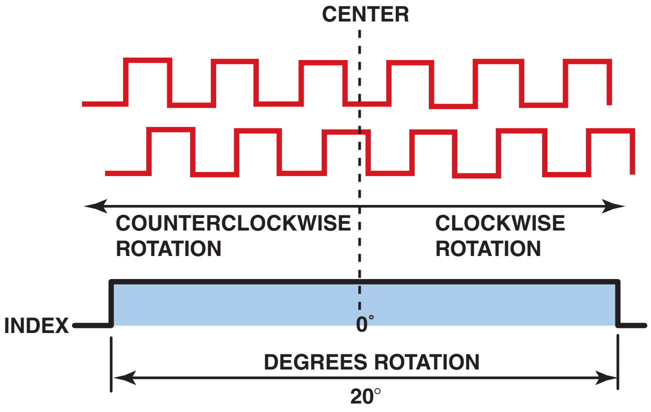

FIGURE 120–41 The output of a typical digital steering angle sensor.

sensor that measures the on and off segments of the light. These sensors produce a digital square wave signal with the frequency or pattern depending on the speed and direction the wheel is turning. ● **SEE FIGURE 120–41**.

RESETTING STEERING ANGLE SENSORS Many vehicles require the SAS be reset or recalibrated after an alignment is performed or parts in the steering system are replaced. There are two basic types of reset procedures including

1. **Self-calibration**—Some newer vehicles can self-calibrate by having the wheel turned from lock to lock and then centered and cycling the key or when they are driven straight on a level road for a certain amount of time.
2. **Scan tool calibration**—Many systems require recalibration using a scan tool or a special tester that plugs into the data link connector (DLC).

Check service information for the exact procedure to follow for the vehicle being aligned and serviced.

The following chart lists common alignment problems and their probable causes.

Symptom-Based Alignment Guide

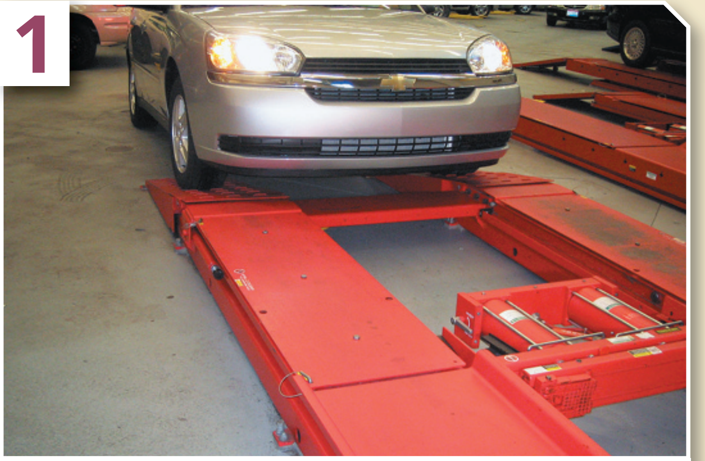
Problem	Probable Causes
Pull left/right	Uneven tire pressure, tire conicity, mismatched tires, unequal camber, unequal caster, brake drag, setback, suspension/frame sag, unbalanced power assist, bent spindle, bent strut, worn suspension components (front or rear), rear suspension misalignment.
Incorrect steering wheel position	Incorrect individual or total toe, rear wheel misalignment, excessive suspension or steering component play, worn rack-and-pinion attachment bushings, individual toe adjusters not provided.
Hard steering	Improper tire pressure, binding steering gear or steering linkage, low P/S fluid, excessive positive caster, lack of lubrication, upper strut mount(s), worn power steering pump, worn P/S belt.
Loose steering	Loose wheel bearings, worn steering or suspension components, loose steering gear mount, excessive steering gear play, loose or worn steering coupler.
Excessive road shock	Excessive positive caster, excessive negative camber, improper tire inflation, too wide wheel/tire combination for the vehicle, worn or loose shocks, worn springs.
Poor returnability	Incorrect camber or caster, bent spindle or strut, binding suspension or steering components, improper tire inflation.
Wander/instability	Incorrect alignment, defective or improperly inflated tires, worn steering or suspension parts, bent spindle or strut, worn or loose steering gear, loose wheel bearings.
Squeal/scuff on turns	Defective or improperly inflated tires, incorrect turning angle (TOOT), bent steering arms, excessive wheel setback, poor driving habits (too fast for conditions), worn suspension or steering parts.
Excessive body sway	Loose or broken stabilizer bar links or bushings, worn shocks or mountings, broken or sagging springs, uneven vehicle load, uneven or improper tire pressure.
Memory steer	Binding steering linkage, binding steering gear, binding upper strut mount, ball joint, or kingpin.
Bump steer	Misalignment of steering linkage, bent steering arm or frame, defective or sagged springs, uneven load, bent spindle or strut.
Torque steer	Bent spindle or strut, bent steering arm, misaligned frame, worn torque strut, defective engine or transaxle mounts, drive axle misalignment, mismatched or unequally inflated tires.

ALIGNMENT GUIDE

ALIGNMENT

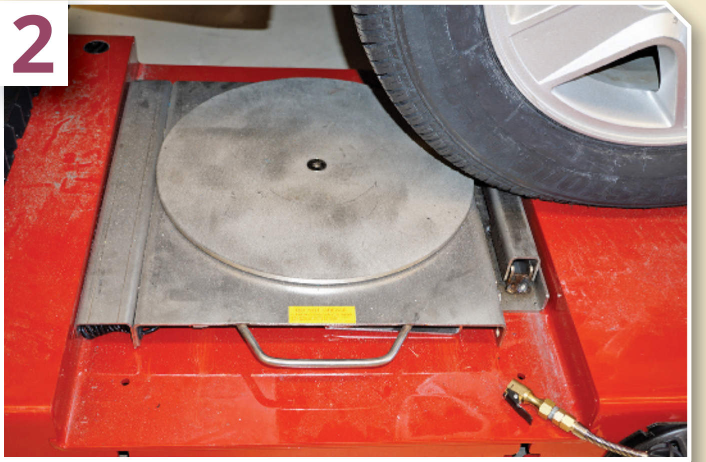
STEP BY STEP

1



Begin the alignment procedure by first driving the vehicle onto the alignment rack as straight as possible.

2

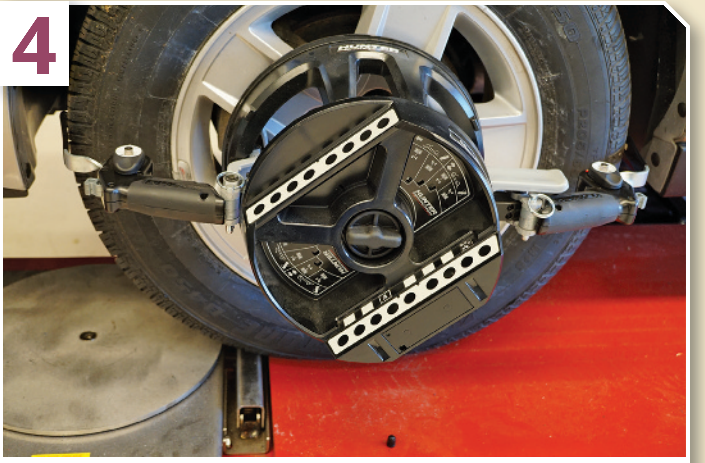


Stop just short of the turn plate and position the plate to center it on the tire tread.

3

Check and adjust tire pressures and perform the prealignment checks necessary to be assured of proper alignment.

4



Securely mount the targets or alignment heads.

CLUTCH ASSEMBLY

PURPOSE AND FUNCTION The clutch assembly is located between the engine and the transmission/transaxle. The purpose and function of a clutch include the following:

- To disconnect engine power from the transmission/transaxle to permit the engine to remain running when the vehicle is stopped with the transmission in gear and to permit the transmission/transaxle to be shifted
- To connect and transmit engine torque to the transmission/transaxle
- To dampen and absorb engine power impulses and drive train vibration
- To provide a smooth engagement and disengagement of torque between the engine and the transmission/transaxle

PARTS INVOLVED A clutch assembly consists of a **clutch disc** that is splined to the input shaft of the transmission/transaxle. When the driver depresses the clutch pedal, a **release bearing**, also called a **throwout bearing**, is forced against the diaphragm spring, part of the clutch cover assembly. This lifts the **pressure plate** releasing the clutch disc. The clutch cover assembly is bolted to and rotates with the flywheel. ● **SEE FIGURE 121–1.**

CLUTCH OPERATION The flywheel and pressure plate assembly are drive members because they are connected to the engine crankshaft and rotate anytime the engine is running. The clutch disc is a driven member and only rotates when the clutch pedal is released, which forces the disc to rotate with the flywheel and pressure plate assembly. Basic operation includes the following:

- When force is exerted on the center of the diaphragm spring by the release bearing, the apply force is released

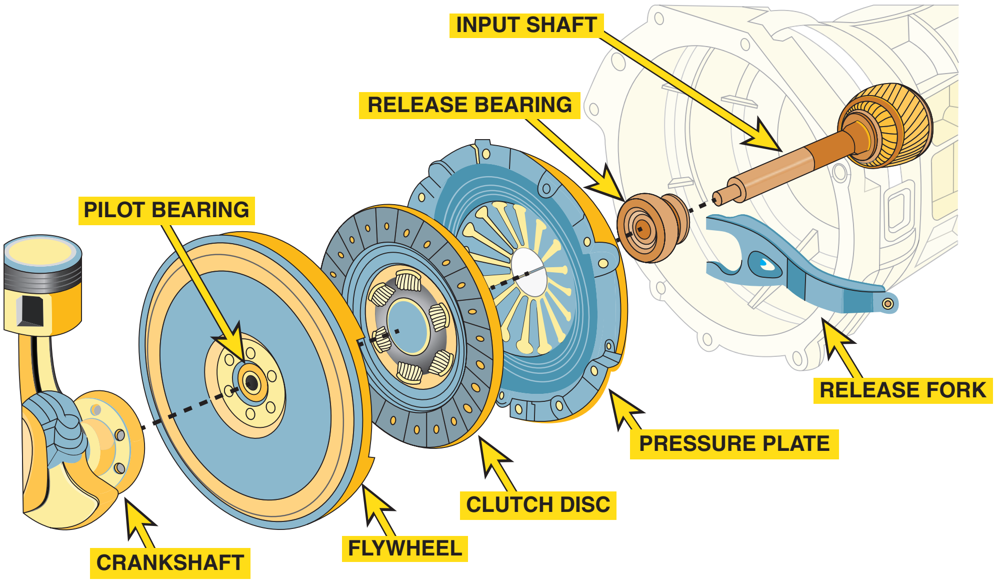

FIGURE 121–1 Typical automotive clutch assembly showing all related parts.

from the clutch disc that had been squeezed between the engine flywheel and the pressure plate.

- With the pressure removed from the clutch disc, the engine can be operated without transferring torque to the transmission/transaxle. Using a clutch also permits the transmission/transaxle to be shifted easily because a shift cannot be made easily if the transmission/transaxle is transferring engine torque.
- When the driver releases force on the clutch pedal, the pedal return spring and the diaphragm spring combine to return the clutch pedal to its at-rest position (clutch-engaged position).
- When the clutch pedal moves up, the pressure on the release bearing is released and the force against the pressure plate diaphragm spring is released, allowing the spring force of the pressure plate to clamp the clutch disc tightly between the flywheel and the pressure plate. ● **SEE FIGURE 121–2.**

Additional related parts include the **pilot bearing** (or **bushing**) that supports the front of the transmission input shaft. ● **SEE FIGURE 121–3.**

The release bearing is often supported and rides on the **front bearing retainer** (release bearing support shaft), also called a **quill**, or candlestick.

To summarize:

- When the clutch pedal is up, the clutch is engaged. (The pressure plate is pressing the clutch disc against the flywheel and rotating together.)
- When the clutch pedal is down (depressed), the clutch is disengaged. (The clutch disc is free and not rotating with the pressure plate.)

CLUTCH DISCS

PURPOSE AND FUNCTION

The clutch disc is splined to the input/clutch shaft of the transmission/transaxle. The purpose of the clutch disc is to transfer engine torque from the flywheel to the input shaft of the transmission/transaxle. The clutch disc is located between the flywheel and the pressure plate where it is clamped between the two when the clutch is engaged. The pressure plate spring exerts spring pressure against the pressure plate, which forces the disc against the flywheel.

COEFFICIENT OF FRICTION

The coefficient of friction, abbreviated with the Greek letter mu (μ), is the relative amount of friction between two surfaces. There must be friction between the members of the clutch friction surfaces for the clutch to function correctly:

- If the coefficient of friction of the clutch is too low, it might slip and not transmit the required torque.
- If the friction coefficient is too high, the clutch would become more aggressive and “grabby,” and engagement would be harsh and severe.

Each vehicle manufacture specifies the coefficient of friction for each vehicle. If a different clutch friction disc is installed or the lining becomes contaminated, then the coefficient can change and result in slippage or harsh clutch engagement. ● **SEE FIGURE 121–4.**

CLUTCH FRICTION MATERIAL

The clutch friction material must be able to withstand the heat generated by the friction during engagement and disengagement. Older clutch friction discs used a mixture of either molded or woven asbestos with various filler and binder materials. Asbestos is nearly an ideal friction material for brake lining and clutch facing because it has a very good coefficient of friction, excellent heat characteristics, and low cost. However, the possibility of technicians getting cancer from inhaling asbestos fibers has greatly reduced its use. Asbestos was replaced with fiberglass, aramid nonmetallic compounds, and/or metallic materials to obtain the desired friction and wear characteristics. Some of the materials used include

- powdered iron
- copper
- graphite
- ceramics

(b) When the clutch is in the engaged position (clutch pedal up), the diaphragm spring exerts force on the clutch disc, holding it between the flywheel and the pressure plate.

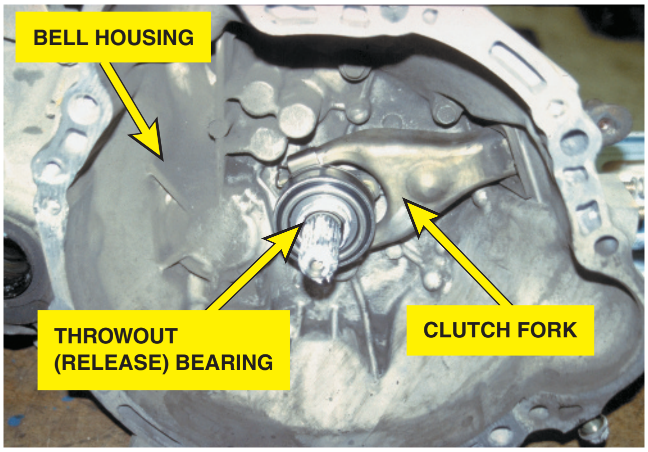

FIGURE 121–3 The transmission has just been removed. Note that this type of transmission incorporates the bell housing, which was therefore removed at the same time as the transmission. The clutch fork and throwout (release) bearing also came off together. All that remained attached to the engine was the flywheel, clutch disc, and pressure plate.

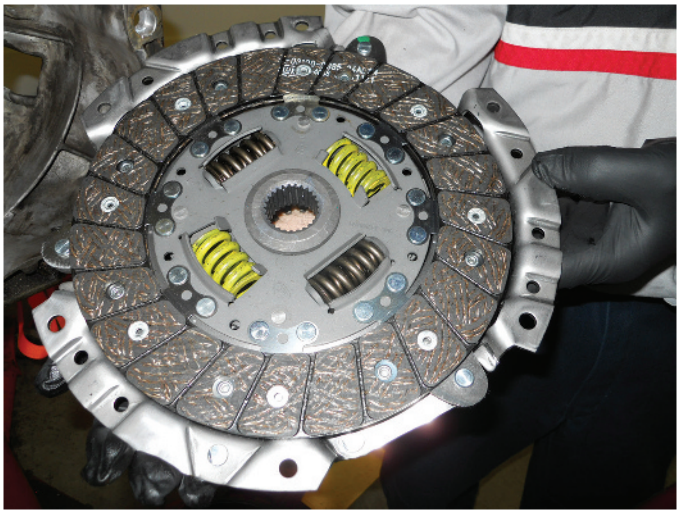

FIGURE 121–4 A replacement clutch is designed to meet the same friction specifications of the original so the new clutch will operate like new.

SURFACE GROOVES

Most nonmetallic facings have a series of radial grooves cut across their surface. The purpose and function of the grooves include

- Wipe dust and dirt from the surfaces of the flywheel and pressure plate.
- Allow airflow to help cool the friction surfaces.
- Prevent a vacuum that might cause the friction surfaces to stick together during disengagement. Sticking during disengagement will cause clutch drag.
- Some metallic discs have a series of radial slots cut across the facing, which allows the disc to expand without warping when it gets hot.

MARCEL SPRING

In the space between the friction surfaces is a wavy spring steel material called a **cushion spring** or **marcel spring**. ● **SEE FIGURE 121–5.**

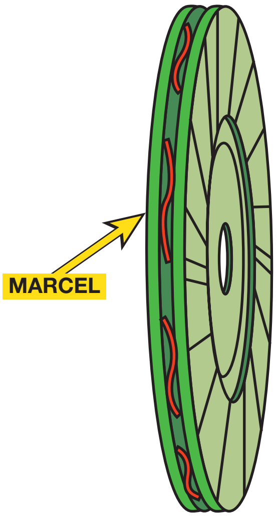

FIGURE 121–5 A marcel is a wavy spring that is placed between the two friction surfaces to cushion the clutch engagement.

The marcel spring helps to absorb the initial shock of rapid engagement and allows for a smooth engagement of the clutch.

RIVETS

The facing of the clutch disc is attached to the steel marcel spring by a series of brass rivets that are installed in counter bored holes or by bonding, which involves attaching the lining to the steel marcel spring by using adhesives (gluing). Some metallic facings are formed directly onto a steel backing. If there is less than 0.015 in. (0.38 mm) of facing above the rivets or backing, a disc is considered worn out.

HUB AND DAMPENER ASSEMBLY

The clutch hub has internal splines (from 10 to 26 teeth) that slide on the external splines of the transmission input/clutch shaft. Each time the clutch is engaged, the disc must slide forward slightly to contact the flywheel, and it must slide back to prevent drag on the flywheel when the clutch is disengaged. ● **SEE FIGURE 121–6.**

Around the center hub of the clutch disc are **torsional dampers** that are coil springs or rubber plugs that help dampen engine firing pulses from being transmitted into and through the transmission/transaxle.

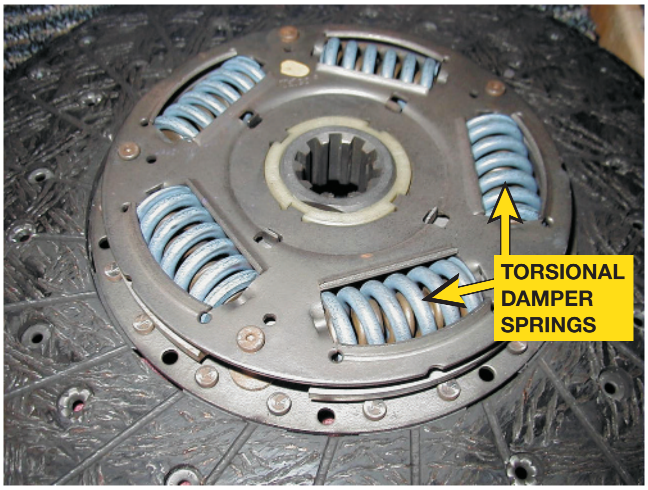

FIGURE 121–6 A typical stock clutch friction disc that uses coil spring torsional dampers.

An engine produces uneven power impulses that cause torsional vibration. The torsional damper reduces the torsional vibrations that result from the uneven engine power impulses from the rest of the drivetrain:

- As an engine goes through its power cycle, the crankshaft will speed up and slow down during each revolution.
- If these slight speed fluctuations are not removed by the damper, they could cause "gear rattle," vibration, noise, and increased wear.

The damper assembly is composed of the hub with four to eight openings, with one or more springs for each extension, a spring washer, and a friction washer. These parts are fitted between the web of the disc and a metal retainer and are held together by a series of rivets called *stop pins*, which also keep the hub from revolving too far, usually about 0.037 inch (9.5 mm). The damper springs are positioned by a series of windows in the web and retainer. The torque must pass through the damper springs on its way from the engine to the transmission, and any power impulses that tend to speed up the clutch hub will compress the springs. The springs will re-extend when there is a torque lag.

PRESSURE PLATES

PURPOSE AND FUNCTION

The purpose of the pressure plate assembly is to exert a force on the clutch disc so that engine torque can be transmitted from the engine to the transmission/transaxle. The required strong clamping force is provided by the pressure plate spring(s).

COMPONENT PARTS

The pressure plate assembly is a combination of

- Cover (also called a *hat*)
- Pressure springs, or diaphragm spring
- Release levers (also called *fingers*) on coil spring types
- Cast iron pressure ring (*driving plate*) that contacts the friction disc

A strong pressure plate spring force must be released by the force of the driver's foot to disengage the clutch. Most pressure plate covers are made of stamped steel with a nodular cast iron pressure ring, also called a driving plate. A smooth, machined area on one side forms the friction disc contact surface. When the clutch engages, spring force pushes the pressure plate toward the flywheel, so the friction disc is clamped between the flywheel and the pressure plate.

TYPES

Several styles of pressure plates have been used, including

- A coil spring style of pressure plate that uses coil springs and three or four release levers. A coil-spring-style pressure plate is also called the **lever style** because it uses levers to compress the coil springs. This type of pressure plate is often called a "three-finger" pressure plate. ● **SEE FIGURE 121–7**.
- A diaphragm spring style is the most used pressure plate design. It uses one large, round spring-steel spring to apply even force on the clutch disc called a *Belleville spring*. The relatively low height of the diaphragm design is highly favored for transverse engine vehicles where engine and transaxle lengths are critical. ● **SEE FIGURE 121–8.**

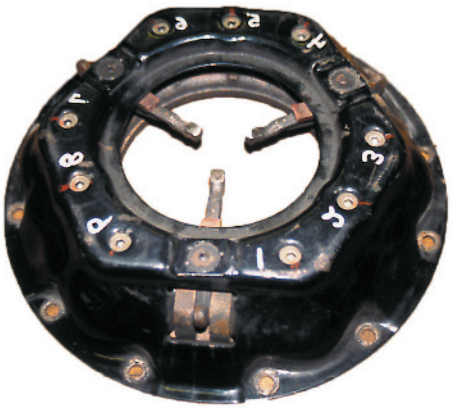

FIGURE 121–7 A coil spring (lever style) clutch pressure plate.

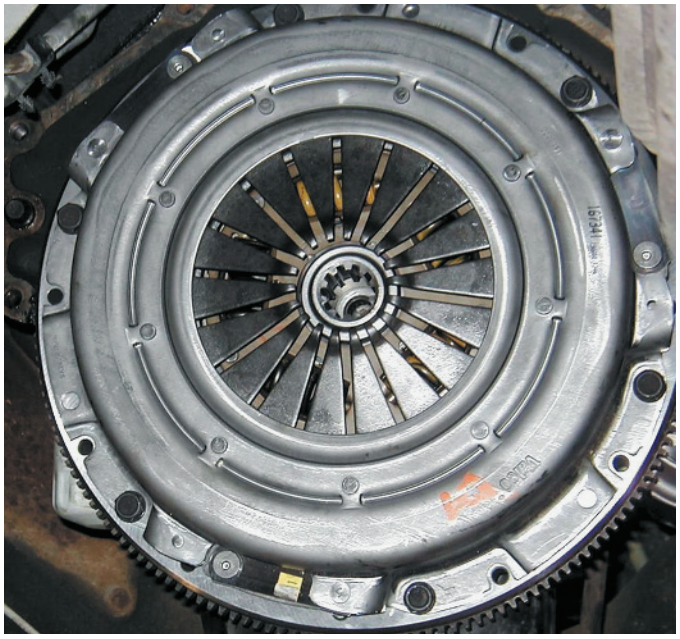

FIGURE 121–8 Typical diaphragm-style pressure plate that uses a Belleville spring.

ADVANTAGES OF A DIAPHRAGM-TYPE CLUTCH

Diaphragm-type pressure plates have several advantages over the other types including

1. Diaphragm-type clutch pressure plates tend to be smaller assemblies, weigh less, and have fewer parts than coil spring assemblies. The one-piece diaphragm spring does the job of all the release levers and coil springs in a **coil spring clutch**.
2. The driver must push harder on the clutch pedal to disengage a coil spring clutch than to disengage a comparable diaphragm spring design. The pedal effort for a coil spring clutch increases the farther down the pedal is pushed.
3. The pedal effort for a diaphragm spring clutch decreases during the second half of pedal travel. As the friction disc wears, coil springs expand and lose some of their clamping force. In contrast, the design of the diaphragm spring tends to increase its clamping force as the friction disc wears to half its original thickness. Then, as the friction disc continues to wear, the clamping force of the spring gradually returns to its original level. This happens without any obvious change in clutch pedal effort.

PRESSURE RING Pressure plate diameter is measured at the outside diameter of the pressure plate ring. It should always be the same size or slightly larger than the disc diameter. A pressure ring is simply a flat, heavy ring usually made from nodular cast iron. The heavy weight is necessary to dissipate heat and provides a heat sink so as not to warp. It also provides sufficient strength so it will spread the spring force evenly onto the disc. For high-RPM use, the ring is made from cast steel because centrifugal force can cause a cast iron ring to fail.

- When a clutch slips, heat is generated at the friction surfaces, and this heat will warm the facing, the pressure ring, and the flywheel.
- Excess heat will cause the pressure ring to expand to the point of warpage, destroying its flatness and causing poor ring-to-disc facing contact.
- The greater the mass of the pressure ring, the less the temperature will rise because the heat will spread through more metal, which will hold the heat longer.

Torque enters the pressure ring from the cover, either through a drive strap or a boss where the release levers extend through openings in the cover. Torque passes out through the friction contact with the facing on the disc.

TECH TIP

High-Engine Speed Shifting

Centrifugal force can also affect a diaphragm clutch. During a very high-RPM disengagement, if the fingers are moved far enough forward so that they pass over center (beyond flat), centrifugal force will try to throw the weight of the fingers in the other direction. Some people have experienced this during a shift at high RPM when the pedal stays on the floor while the engine overrevs. To prevent this, "bent finger" diaphragms are used for installations where high-RPM shifts might occur. The shape of the fingers keeps them from traveling over center. ● **SEE FIGURE 121–9.**

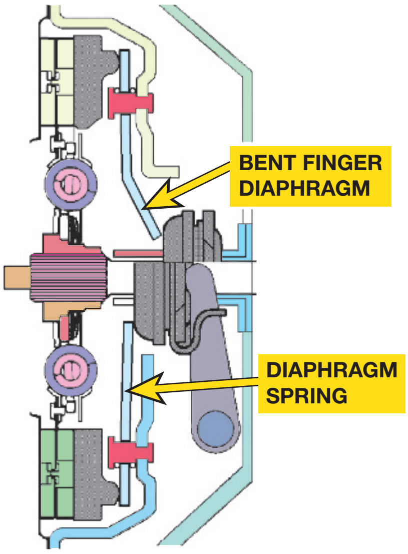

FIGURE 121–9 A bent finger diaphragm clutch. The shape of the fingers keeps the fingers and release bearing from going past center during clutch release.

COVER (HAT) The cover (hat) is the stamped-steel housing that transmits the torque from the flywheel to the pressure ring. It also provides a mounting place for the springs and release levers, where used, and it must be strong enough to contain the various forces without distorting.

FLYWHEELS

PURPOSE AND FUNCTION The engine flywheel serves four basic purposes:

1. Smooths out or dampens engine power pulses
2. Absorbs some of the heat created by clutch operation
3. Provides the mounting surface for the starter motor ring gear
4. Provides the application surface for the clutch friction disc

INERTIA A flywheel is heavy, or has a large mass, which creates inertia. Inertia is the tendency of a moving object to remain in motion, because of its weight, unless forced to slow. This inertia acts upon crankshaft rotation to smooth out or dampen engine power pulses. On a running engine, the crankshaft speeds up as a cylinder fires, then slows due to internal engine friction until the next cylinder fires. The inertia provided by the flywheel mass tends to keep crankshaft speed more constant.

Whenever friction exists between two moving parts, heat is generated. The flywheel absorbs some of the heat created by clutch operation by acting as a heat sink for the clutch friction disc.

STARTER RING GEAR An external ring gear is pressed or welded onto the flywheel along its outer circumference. The starter-drive gear meshes with the flywheel ring gear. Through gear reduction, the flywheel transfers starter motor rotation to the crankshaft to crank the engine. When the starter motor is engaged, the starter motor will spin but the engine will not crank if the ring gear on the flywheel is broken. Often the ring gear can be replaced separately without having to replace the flywheel in the event of a failure. ● **SEE FIGURE 121–10.**

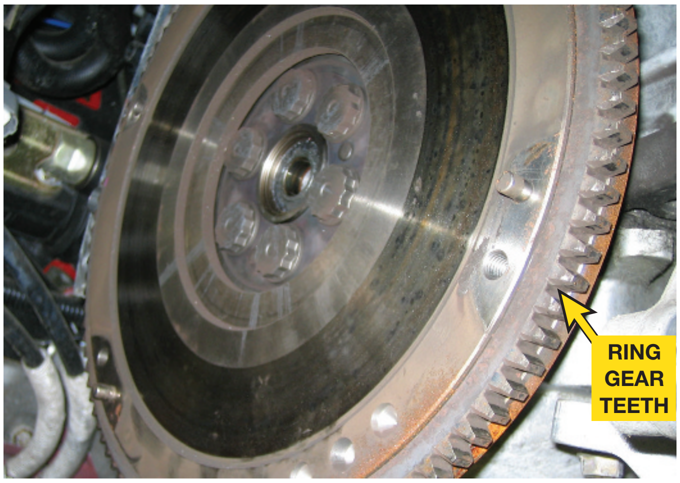

FIGURE 121–10 The ring gear, which is attached to the outer rim of the flywheel, provides the teeth needed to mesh with the starter pinion gear.

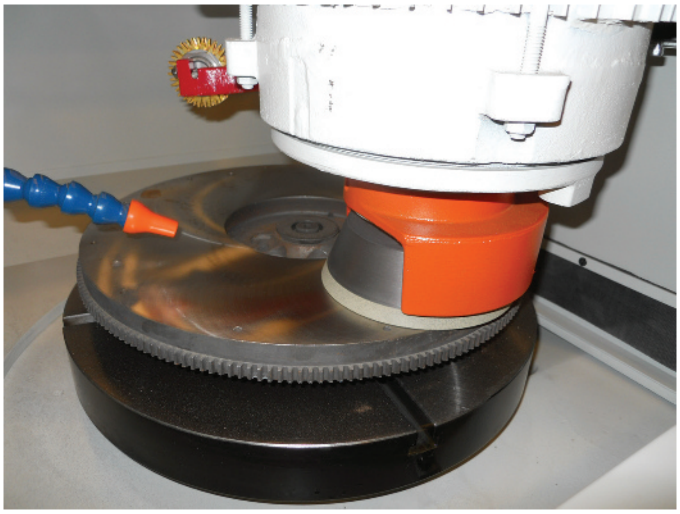

FIGURE 121–11 A flywheel being machined (ground) to provide the correct surface finish for the replacement clutch disc.

CONSTRUCTION The flywheel is constructed of cast iron and attaches to the end of the engine crankshaft. The carbon content of the cast iron (about 3%) provides a suitable surface for the clutch disc.

The carbon, in the form of graphite, acts as a lubricant to help provide a smooth engagement of the clutch. The face on the transmission side of the flywheel has a smooth, machined area that creates the application surface for the clutch friction disc. This surface must be properly finished to allow adequate slippage as the clutch engages and disengages, and to prevent slippage when the clutch is engaged. Being made from cast iron makes resurfacing easy. ● **SEE FIGURE 121–11.**

DUAL-MASS FLYWHEELS

PURPOSE AND FUNCTION Some vehicles, especially high-performance vehicles and vehicles equipped with diesel engines, use a dual-mass flywheel. The purpose of a dual-mass flywheel is to dampen engine vibrations and keep them from being transmitted to the passenger compartment through the transmission and shift linkage.

PARTS AND OPERATION A dual-mass flywheel consists of two separate flywheels connected at the center, with damper springs, friction material, and ball bearings between the two that allows some movement between the primary and secondary flywheel. By allowing a slight amount of movement between the two flywheels, the damper springs absorb engine torque peaks and normal vibration to provide smoother drive train operation. The damper assembly is completely sealed because it also contains a fluid or lubricant, typically silicone-based, which also helps absorb vibration and transmit torque. Typically, the two flywheels twist out of phase with each other by up to about 60 degrees to absorb torsional oscillations. The starter ring gear mounts on the primary flywheel. Power from the starter motor does not have to flow through the damper assembly to reach the engine crankshaft. The pilot bearing is also attached to the primary flywheel, and the clutch friction surface is usually the secondary flywheel. Assemblies with dual-mass flywheels often use a clutch disc that does not include the torsional load springs. ● **SEE FIGURE 121–12.**

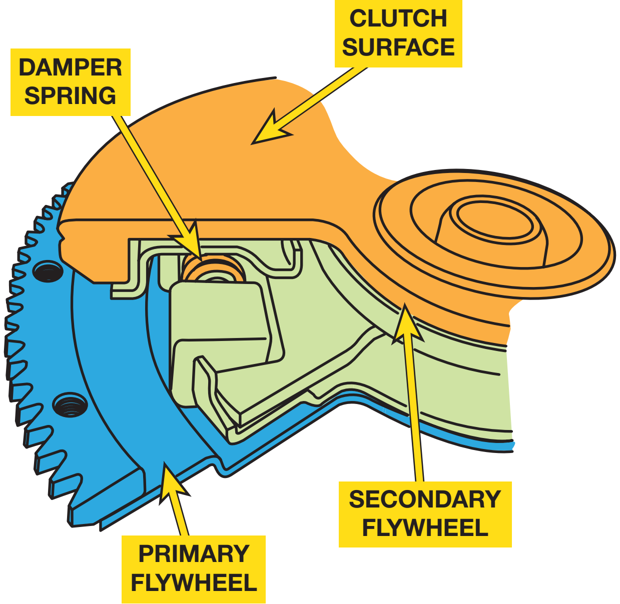

FIGURE 121–12 A dual-mass wheel consists of two flywheels connected with a spring between them to help absorb engine pulsations.

NOTE: If the dual-mass flywheel fails, the symptom is the same as a slipping clutch. The torque-limiting friction material connecting the primary and secondary flywheels can fail. This failure requires the replacement of the flywheel assembly.

PILOT BEARINGS

PURPOSE AND FUNCTION The engine end of a transmission input (clutch) shaft is supported by a pilot bearing that is pressed into the end of the crankshaft. ● **SEE FIGURE 121–13.**

NEED FOR A PILOT BEARING The transmission input shaft goes all the way from the transmission, through the clutch assembly, to the engine. Transmission bearings support the transmission end of the shaft. The pilot bearing or bushing supports it at

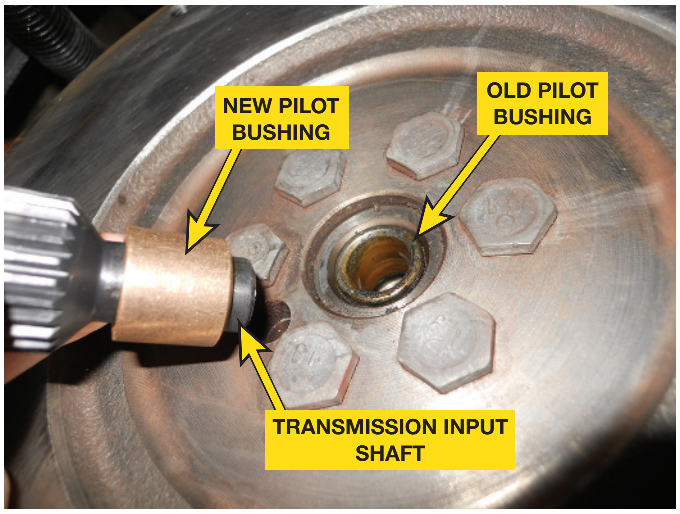

FIGURE 121–13 A pilot bearing or bushing, such as one being used on the rear-wheel-drive pickup truck, is pressed into the end of the engine crankshaft and supports the input shaft of the transmission.

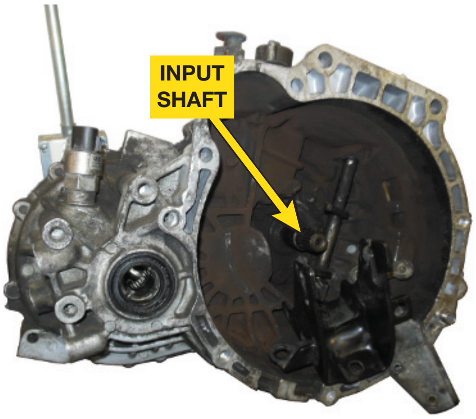

FIGURE 121–14 A manual transaxle assembly showing the short input shaft.

the engine end. A front-wheel-drive vehicle has a transaxle with an input shaft supported by a pair of bearings and a short input shaft that may not reach all the way to the flywheel. This design does not need a pilot bushing or bearing to support the engine end of the input shaft. ● **SEE FIGURE 121–14.**

CONSTRUCTION

Pilot bearings can be constructed using the following:

- Sintered bronze oilite bushing
- Needle bearing
- Ball bearing

The oilite bushing is impregnated with oil to lubricate it, whereas the other types of bearings are usually lubricated and then sealed.

OPERATION

At the engine, the transmission input shaft rests inside a small bore in the flywheel or crankshaft flange. The pilot bearing or bushing supports the engine end of the input shaft and provides a low-friction surface for the shaft to ride on. This keeps the shaft and friction disc perfectly aligned with the flywheel and pressure plate. The pilot bearing or bushing rotates with the crankshaft while the engine is running. When the clutch is released, the input shaft does not rotate when the engine is running. The pilot bearing or bushing lowers the friction between these two moving parts. ● **SEE FIGURE 121–15.**

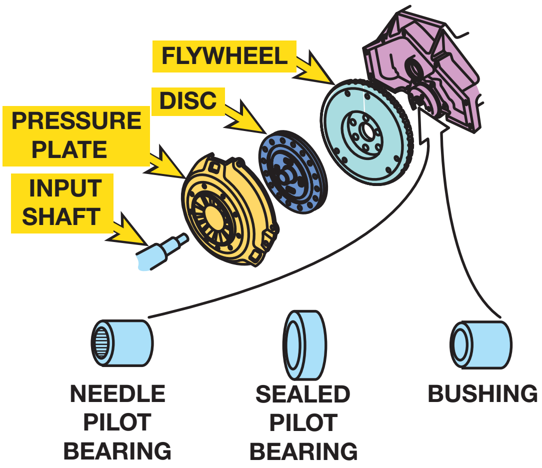

FIGURE 121–15 Pilot bearings (bushings) are made in several different designs depending on the application.

CLUTCH PEDAL LINKAGE

PURPOSE AND FUNCTION

The purpose and function of the clutch pedal linkage are to transfer the force the driver exerts on the clutch pedal to the release bearing.

TYPES OF CLUTCH LINKAGE

There are three methods of transferring the force of the driver's foot to the release (throwout) bearing, including

1. **Levers and rods.** Mechanical linkage uses a series of levers and rods, to move the release fork against the throwout bearing. This method was commonly used on many older vehicles, including the muscle cars of the 1960s and early 1970s. The force applied to the clutch pedal is directed to an equalizer bar (also known as a Z-bar) that is mounted on pivot shafts to reverse the direction of the force. This type of linkage ends at the **clutch fork** after it passes through an equalizer shaft that pivots from both the engine/bell housing and the vehicle body. Mechanical linkage includes an adjustment at some point so that free travel can be adjusted. Free travel (also called free play) is the slight clearance exists (about 1 in. [25 mm] measured at the pedal, or about 1/16 in. [2 mm] measured at the clutch fork).
2. **Cable operation.** A cable is used similar to a brake cable on a bicycle. Cable linkage consists of a steel cable attached to the clutch pedal. The clutch cable is routed to the engine/bell housing, where it can pull on the clutch fork/lever. Much of the cable is enclosed in a housing or conduit so that it can be routed around corners or obstacles. Although simple and inexpensive, cables have a drawback in that they develop internal friction through time, which makes them harder to operate. Older vehicles include a method of manual adjustment at the end of either the cable or cable housing.

   Many vehicles include a self-adjuster mechanism at the clutch pedal and some are adjusted by pulling up on the clutch pedal. The self-adjuster is usually a spring-loaded cam that is mounted onto the pedal when a spring-loaded pawl engages it. The pawl is lifted each time the clutch is disengaged so that the cam's spring can rotate and remove any slack or clearance in the cable. When the pedal is depressed, the pawl's spring returns it to lock the cam to the pedal. ● **SEE FIGURE 121–16.**

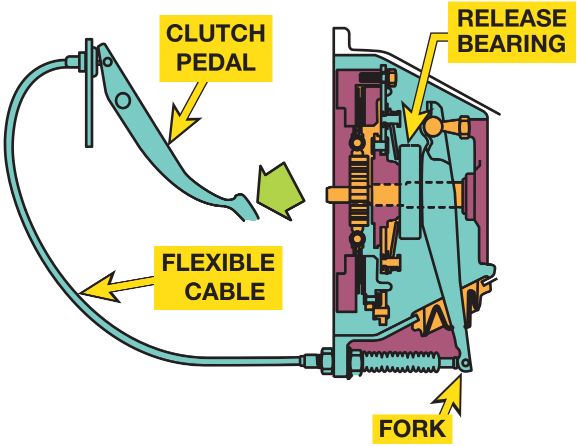

FIGURE 121–16 A typical cable clutch linkage uses a cable to transmit motion from the pedal to the release bearing.

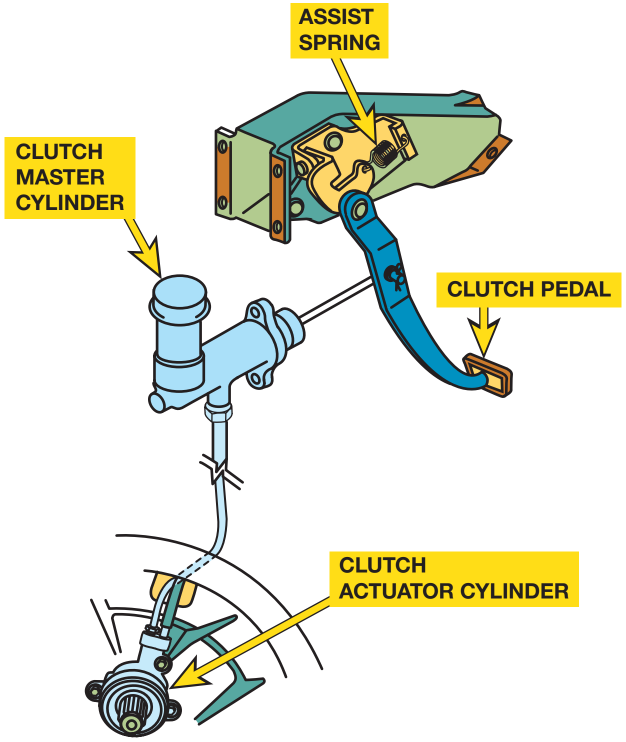

FIGURE 121–17 The actuator cylinder of some systems is concentric to the transmission input bearing retainer. When the clutch pedal is depressed, pressurized fluid is forced from the clutch master cylinder to the actuator cylinder to release the clutch.

3. **Hydraulic.** The most commonly used clutch operating system is hydraulic. A small **master cylinder** is located on the bulkhead and operated by the clutch pedal. This is connected by tubing to an **actuator cylinder** located near the release (throwout) bearing. ● **SEE FIGURE 121–17.**

HYDRAULIC CLUTCH OPERATION A hydraulic system transmits force using a fluid. Liquids cannot be compressed, and if a force is put on liquid at one end of a passage, liquid at the other end of the passage will exert the same force. In a hydraulic clutch system, the input piston in the clutch master cylinder is connected to the clutch pedal.

The output piston is located in the actuator cylinder, and it will operate the release bearing directly or through a clutch fork/lever. The master cylinder and actuator cylinder pistons are connected by metal, reinforced rubber, or plastic tubing.

- When the clutch pedal is depressed, the master cylinder piston forces fluid through the tubing to the actuator cylinder, where the pressure forces the actuator cylinder piston to move the clutch fork/lever.
- When the clutch pedal is up, the pressure plate forces the actuator cylinder piston to return the fluid to the master cylinder.
- When the clutch pedal is up, a compensating port in the master cylinder is opened up between the cylinder bore and the fluid reservoir.
- This port allows for fluid expansion or contraction due to temperature changes, for any air to leave the fluid, and in many cases, for self-adjustment for disc wear.
- Because air can be compressed, any air trapped in a hydraulic system will cause mushy, spongy pedal, or incomplete operation. DOT 3 brake fluid is generally used in clutch hydraulic systems.
- Many systems use an actuator cylinder that is concentric to the bearing retainer and has the release bearing connected directly to it. Some vehicles use an actuator cylinder that is mounted on the exterior of the bell housing.

RELEASE (THROWOUT) BEARING

PURPOSE AND FUNCTION The release (throwout) bearing rides on the transmission front bearing retainer. The clutch operating system moves the clutch release bearing when the driver presses or releases the clutch pedal. Most systems move the release bearing toward the flywheel to disengage the clutch.

OPERATION The release bearing presses against the diaphragm spring fingers or coil spring levers. This takes spring force off the pressure plate so that it no longer clamps the friction disc against the flywheel. The diaphragm spring fingers or coil spring levers rotate at crankshaft speed, but the clutch operating system is mounted on the transmission housing and does not rotate. The release bearing is the point where the fixed, stationary clutch operating system meets the rotating clutch assembly.

RELEASE BEARING CONSTRUCTION Most clutch release bearings are ball bearings. The bearing absorbs a thrust load when its outer race presses against the diaphragm spring fingers or coil spring levers. When the outer race contacts the spring fingers or levers, it must rotate with them at engine crankshaft speed. The inner bearing race is pressed onto an iron hub or sleeve. In some designs, the inner bearing race and sleeve are machined as one piece. The inner bearing race and sleeve are stationary and do not spin when the outer race spins.

RELEASE BEARING LOCATION The transmission front bearing retainer has a long, hollow tube extending toward the engine. The release bearing sleeve slides on the outer surface of this tube, which is also commonly called (slang):

- Quill
- Quill shaft
- Candlestick

In a typical system, the outside of the release bearing sleeve has grooves or raised flat surfaces that fit into the clutch release fork. A snap ring, spring clips, or lock pins secure the release bearing to the release fork. The clutch operating system pivots the release fork back and forth when the driver presses and releases the clutch pedal. The pivoting motion of the fork slides the release bearing away from or toward the engine to engage or disengage the clutch.

TYPES OF RELEASE BEARINGS If the clutch operating system self-adjusting, then there is no clearance between the release bearing outer race and the diaphragm spring fingers or coil spring levers.

- The release bearing outer race constantly turns at engine crankshaft speed. This is called a constant-running release bearing. In some self-adjusting systems, a snap ring holds the outer race to the spring fingers. This design is typical of pull-type clutch operating systems that move away from the flywheel to disengage the clutch.

- If the clutch operating system does not self-adjust, then there must be some clearance between the release bearing outer race and the spring fingers when the clutch is engaged. The outer race does not contact the spring fingers and so it does not turn. As the driver depresses the clutch pedal, the release bearing moves into contact with the fingers and the outer race begins to rotate with them. This type of release bearing is not designed to rotate constantly. If the clutch is not adjusted properly and there is no clearance, the release bearing spins constantly and wears out quickly. ● **SEE FIGURE 121–18.**

CLUTCH PEDAL SWITCH

PURPOSE AND FUNCTION A **clutch pedal position switch** is used to signal the starter circuit that the clutch is disengaged, which prevents starter operation unless the clutch pedal is depressed. Some vehicles will have a clutch pedal position switch at the pedal stop that is normally closed in addition to a **safety switch**. This is for disengaging the cruise control.

OPERATION The switch is normally electrically open, and it closes when the pedal is completely depressed. This completes the circuit from the ignition switch to the starter relay, and when the circuit is completed, the starter relay energizes the starter, cranking the engine. This safety feature prevents the vehicle from moving accidentally when the starter is engaged.

(b) A style of release bearing that includes the actuator cylinder, sometimes called a *concentric cylinder*. (c) A combination release bearing and actuator cylinder showing the two hydraulic lines. The lower line is from the master clutch cylinder, and the upper line is used to bleed air from the hydraulic system.

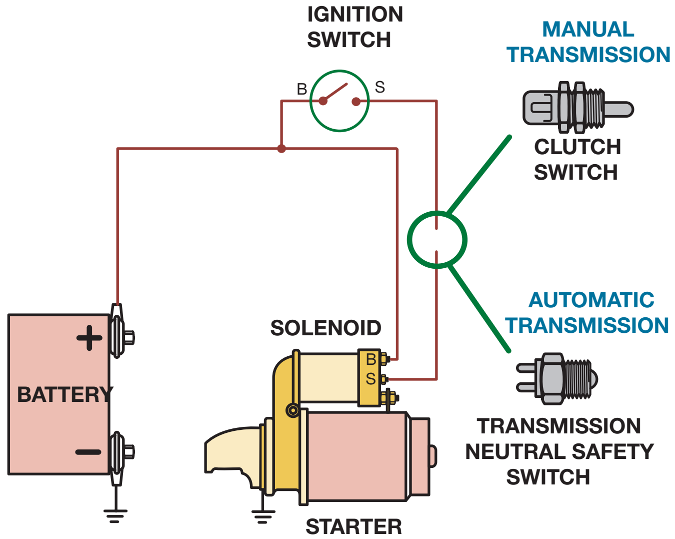

FIGURE 121–19 The clutch pedal switch is used to prevent the engine from cranking unless the clutch pedal is depressed.

CAUTION: Not all vehicles are equipped with a clutch safety switch, so it is very important that the transmission be placed in neutral and/or the clutch fully depressed before starting the engine.

● **SEE FIGURE 121–19.**

CLUTCH DIAGNOSIS AND REPLACEMENT

SYMPTOMS OF A DEFECTIVE CLUTCH The following symptoms will occur if there is a fault in the clutch or in the linkage or hydraulic system that could prevent the clutch from being fully disengaged:

- The transmission will be difficult (or impossible) to shift into reverse.
- The transmission will be difficult (or impossible) to shift between forward gears.

LEAK DETECTION A drop in fluid level at the reservoir indicates a fluid leak. Normally, facing wear will cause an increase, or rise, in the fluid level, so topping off the reservoir is not necessary or recommended. The cause of a fluid leak is usually found through visual inspection of the cylinders and lines to locate the wetness. Fluid leak repair is done by correcting the fault, which could include

- Tightening a loose line fitting.
- Replacing an O-ring, fluid line or hose.
- Replacing the clutch master cylinder or actuator cylinder.

ACTUATOR CYLINDER TRAVEL Inability to release the clutch completely can be checked by observing actuator cylinder travel as the clutch pedal is depressed. The actuator cylinder should begin moving immediately and travel in a smooth, steady manner. Some manufacturers provide actuator cylinder travel or extension specifications. For example, one manufacturer specifies 0.5 inch (13 mm) of actuator cylinder motion for one complete stroke of the clutch pedal. Insufficient actuator cylinder travel indicates air in the system or a faulty actuator or master cylinder.

CLUTCH SLIPPAGE DIAGNOSIS **Clutch slippage** can be checked easily in a shop; however, a more thorough check can be made during a road test.

To check for slippage in a shop, perform the following steps:

STEP 1 Check and adjust clutch pedal free travel.

STEP 2 Warm up the engine to operating temperature, block the wheels, and apply the parking brake completely.

STEP 3 Shift the transmission into a high gear and let out the clutch pedal smoothly. The engine should stall immediately. A delay indicates slow engagement and slipping.

To check for slippage on a road test, perform the following steps:

STEP 1 Check and adjust clutch pedal free travel.

STEP 2 Drive to an area with very little traffic. Accelerate slowly and drive at 15 to 20 mph (24 to 32 km/h) in the highest transmission gear. Use the lowest speed at which the vehicle will operate smoothly.

STEP 3 Depress the accelerator completely to wide-open throttle and listen to the engine RPM or watch the tachometer. The engine speed should increase steadily as the vehicle accelerates. If the engine speed flares upward, the clutch is slipping and needs service. Slipping becomes even more evident if this test is made while driving up a hill.

CLUTCH SPIN-DOWN TEST Hard shifting into gear from neutral, sometimes accompanied by gear clash, can be caused by a clutch that is not releasing completely. This is called **drag** and is easily checked by a spin-down test. **Clutch spin-down** is the time it takes for the clutch disc and transmission gears to spin to a stop when the clutch is released.

To check clutch spin-down, perform the following steps:

STEP 1 Check and adjust clutch pedal free travel.

STEP 2 Warm up the engine and transmission to operating temperatures.

TECH TIP

Take Precautions

Whenever working on a clutch assembly, most vehicle manufacturers recommend the use of personal protective equipment (PPE) to protect the technician against possible hazards. The items needed include the following:

1. Safety glasses
2. Protective gloves

Because clutch disc material may contain asbestos, precautions should include avoid causing any clutch friction material from becoming airborne by wetting the area.

Check service information for specific precautions recommended by the vehicle manufacturer for the vehicle being serviced.

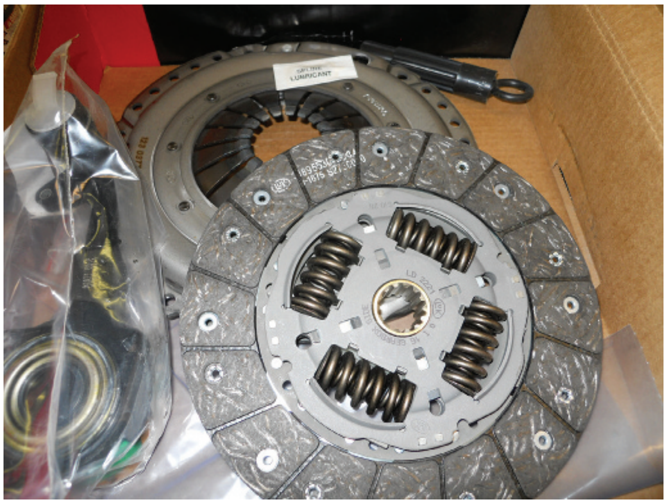

FIGURE 121–20 A typical clutch kit, which includes the clutch disc, pressure plate, and release (throwout) bearing as well as grease for the spline and a clutch disc alignment tool.

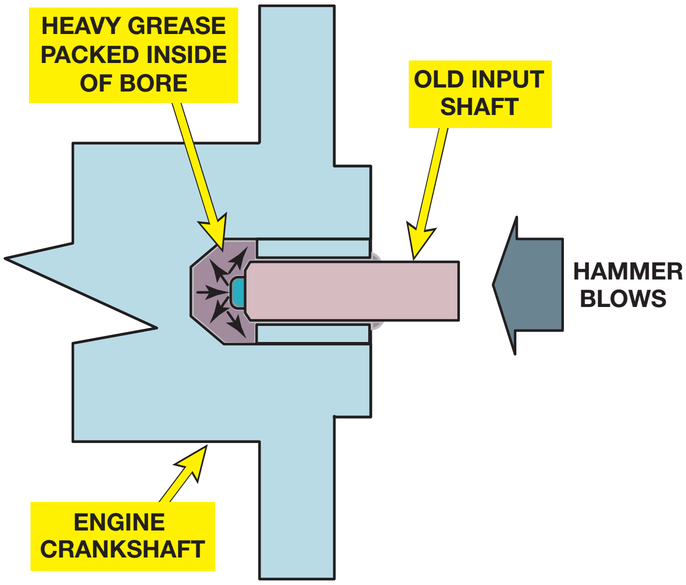

FIGURE 121–21 An old input shaft obtained from a disassembled transmission can be used to force the old pilot bushing out.

STEP 3 With the engine running at idle speed and the transmission in neutral, push in the clutch pedal, wait two seconds, and shift the transmission into reverse (a nonsynchronized gear). The shift should occur silently. **Gear clash** or grinding indicates a dragging clutch that has not released completely. If a clutch fails the spin-down check, it likely needs to be replaced.

CLUTCH REPLACEMENT Clutch replacement, commonly called a *clutch job*, is a fairly expensive and labor intensive repair. During disassembly, each part should be checked to determine if it is the cause of the failure and if it is suitable for reuse. During reassembly, each phase is normally accompanied by checks for proper clearances or operation so that any faulty parts or assemblies can be corrected as early in the assembly as possible.

Clutch replacement normally involves replacing four items:

1. Pressure plate assembly
2. Clutch disc
3. Release bearing
4. Pilot bearing ● **SEE FIGURE 121–20**.

CLUTCH REMOVAL The clutch replacement for a typical rear-wheel-drive vehicle includes the following steps:

1. Hoist the vehicle safely and mark and remove the driveshaft. This step ensures that the driveshaft will be reinstalled correctly and in phase.
2. Disconnect the shift linkage, speedometer connections, and reverse light switch connection as well as the clutch linkage or cable or actuator cylinder.
3. Support the transmission with a transmission jack and then remove the rear cross member and bell housing bolts.
4. Carefully move the transmission toward the rear. Try to keep the transmission level to avoid causing damage to the pilot bearing or clutch components. A slight wiggling of the transmission is usually necessary to allow the input shaft to slide over the spline of the clutch disc.
5. After the transmission has cleared the clutch, it can be lowered and inspected before being reinstalled after the clutch assembly has been replaced.
6. Mark the pressure plate and flywheel if they are to be reused to allow them to be reinstalled in the same location to maintain assembly balance.
7. Remove the clutch pressure plate retaining bolts, and remove the clutch assembly including the release bearing, pressure plate, and clutch disc.

PILOT BEARING A commonly used pilot bushing removal method is to thread a coarse bolt into the bushing so it bottoms against the crankshaft. Further tightening will move the bushing outward. Some vehicle manufactures recommend the use of a special puller. A somewhat messy alternative method to remove a pilot bearing is to fill the cavity behind the bearing with chassis grease and drive a close-fitting round rod or **dowel** into the grease. This will create a hydraulic force behind the bearing, forcing it outward. Soap or wet tissue can also be used. ● **SEE FIGURE 121–21**.

IMPORTANCE OF INSPECTION Technicians should check each part as it is disassembled to determine if it is reusable or why it failed. This identifies any condition that needs special attention before the clutch is reassembled. If the clutch is slipping, the disc and the pressure plate should be replaced. The following sections explain the normal checks to be made during a clutch job.

⚠ WARNING

The clutch driven disc may contain asbestos, which is known to be a cancer-causing agent. Never clean clutch surfaces with compressed air. Avoid inhaling any dust from any clutch surface. When cleaning the clutch surfaces, use a commercially available brake cleaning fluid.

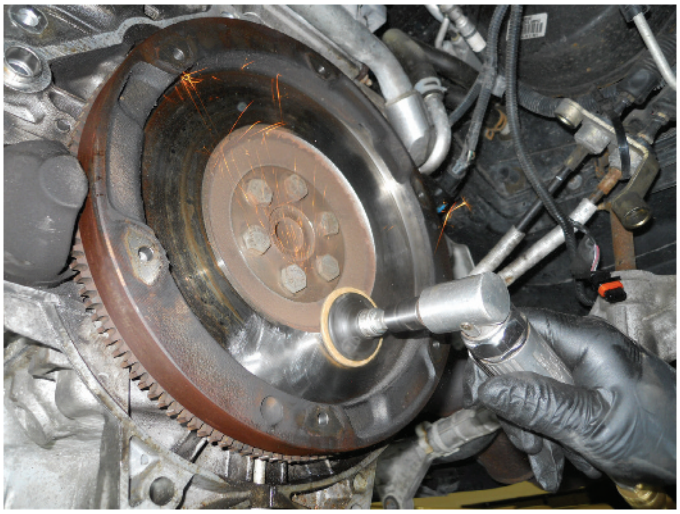

FIGURE 121–22 Using an abrasive disc to remove the glaze and to restore the proper surface finish to a flywheel.

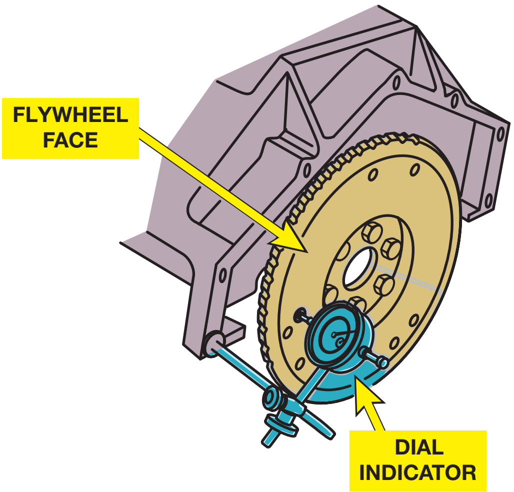

FIGURE 121–23 A dial indicator set up to measure flywheel face or axial runout.

FLYWHEEL INSPECTION The friction surface of the flywheel should be checked for the following:

- Grooves
- Nicks
- Heat damage (discoloration or cracks caused by excessive heat)

Any of these indicates that the flywheel needs to be resurfaced or replaced.

FLYWHEEL RESURFACING Blanchard grinding moves a spinning grinding stone around the flywheel surface. This is the recommended method of resurfacing because it leaves a truly flat surface with a circular, nondirectional pattern. A nondirectional finish promotes rapid disc facing-to-flywheel break-in.

If the friction surface is flat and smooth but highly polished or glazed, some technicians will sand the friction surface using a disc sander with 80- to 120-grit paper. When doing this, the sander is kept in motion while attempting to duplicate the ground finish of a new unit without cutting grooves. ● **SEE FIGURE 121–22**.

FLYWHEEL AXIAL RUNOUT Many flywheels are forged steel, which tends to warp (potato chip shape) or dish if overheated. This is checked by placing a straightedge across the flywheel in several locations. Over 0.0005 inch (0.013 mm) of warpage per inch of diameter is considered excessive. This means that a 12-inch-diameter flywheel can have 0.006 inch (12 × 0.0005) of warpage error.

If there is a vibration concern or an odd wear pattern at the hub of the disc or pressure plate release levers, the flywheel should be checked for excessive runout. Face or axial runout is checked by positioning a dial indicator with the indicating stylus at the outer edge of the flywheel face. ● **SEE FIGURE 121–23**.

To measure flywheel axial runout, perform the following steps:

STEP 1 Mount the dial indicator so the measuring stem is parallel to the crankshaft and pointing directly toward the flywheel contacting the disc friction area, and adjust the indicator to read zero.

STEP 2 Rotate the flywheel while watching the dial indicator. Maintain an even pressure, either inward or outward, to maintain zero crankshaft end play. The variation in reading is the amount of axial runout.

STEP 3 Set up the dial indicator to measure lengthwise flywheel/crankshaft motion, and push and pull on the flywheel and crankshaft in a direction that is parallel to the crankshaft. The dial indicator is measuring crankshaft end play. Normal crankshaft end play should be about 0.002 to 0.010 inch (0.05 to 0.25 mm). Movement greater than specified indicates worn engine crankshaft thrust bearings.

To measure flywheel radial runout, perform the following steps:

STEP 1 Mount the dial indicator so it is at the edge of the flywheel, pointing directly toward the center of the flywheel.

STEP 2 Adjust the dial indicator to read zero.

STEP 3 Rotate the flywheel while watching the dial indicator.

STEP 4 The variation in reading is the amount of radial runout.

Radial runout has a greater effect on balance and vibration than on clutch operation. Runout in either direction greater than 0.010 inch (0.25 mm) is considered excessive axial runout, as little as 0.005 inch (0.1 mm) can cause chatter. If the flywheel is to be removed, place index marks at the crankshaft flange for faster alignment during reassembly. Also inspect the starter ring gear teeth. If they are damaged, replace either the starter gear or the flywheel.

PRESSURE PLATE ASSEMBLY INSPECTION A used pressure plate assembly should be inspected visually for all of the following.

- Friction surface damage
- Release lever wear
- Lever pivot wear
- Cover distortion

Like the flywheel, the friction surface will tend to polish or glaze from normal use. If there is excessive slippage, grooves, heat checks, and warping can occur. Warpage can be checked by placing a straightedge across the friction surface and will show up as a gap between the straightedge and the inner portion of the pressure plate ring. Set the pressure plate on the flywheel without the clutch disc in place. All of the mounting points should meet the flywheel evenly and completely. Any air gaps indicate a distorted clutch cover. Release lever height should be checked after the pressure plate and disc are bolted to the flywheel. Soft reddish-brown rust and highly polished or shiny rough areas around the lever pivots are indications of wear at these points. If any problems are noticed, the pressure plate assembly should be replaced.

CLUTCH DISC INSPECTION If installing a used disc, it should be checked for all of the following:

- Facing thickness
- Damper spring condition
- Wear of the hub splines
- Contaminated or oil soaked facing material (oil or grease on the friction surface can cause clutch grab or chatter)
- Warpage or axial runout

The thickness of the facing can be checked by two different methods:

Method 1. The first method is to place cardboard or a shop cloth over the facing to keep it clean and squeeze the facings together to compress the marcel spring. If specifications are not available, the minimum thickness of the compressed disc should be 0.280 inch (7.1 mm). ● **SEE FIGURE 121–24**.

Method 2. The most popular method is to measure the height of the facing surface above the rivets, which is also called *rivet head depth*. With a new disc, rivet head depth will be about 0.050 inch (1.2 mm). A disc with less than 0.015 to 0.020 inch (0.38 to 0.5 mm) should be replaced. ● **SEE FIGURE 121–25**.

The damper springs and hub splines are checked visually for reddish rust, often called "rust dust" and shiny worn areas as well as loose, broken, or missing springs. **Disc runout** warpage is checked by making an axial runout check. This usually requires a pair of tapered centers or an expanding arbor at true center to the hub splines. The disc is rotated while watching for runout or wobbling of the facing surfaces. More than 0.020 inch (0.5 mm) is excessive, and the disc should be replaced.

A quick check for warpage is to set the disc against the flywheel. The facing should contact the flywheel evenly all around the disc.

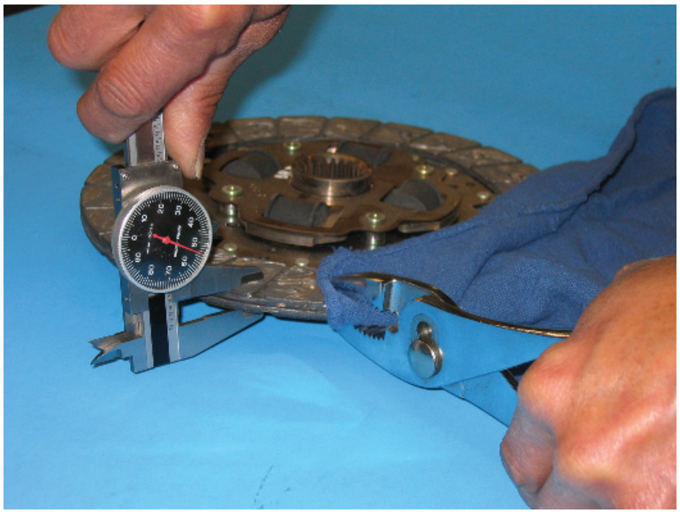

FIGURE 121–24 The thickness of the clutch disc facing can be measured using a dial caliper.

CLUTCH/BELL HOUSING INSPECTION There should not be any oil or grease residue inside the bell housing. If oil is present, check for a leaking front bearing retainer seal or oil galleys plugs or back of the intake manifold. If there has been early failure of the pilot or release bearings, clutch pedal vibration, or the transmission is jumping out of gear, the face and bore surfaces of the bell housing should be checked for excessive runout. Check for excessive runout with a dial indicator attached to the crankshaft, flywheel, pressure plate, or disc, depending on the equipment available and how far the clutch is disassembled.

HOUSING BORE RUNOUT To check clutch housing bore runout, perform the following steps:

STEP 1 Reposition the dial indicator so the measuring stem is inside the bore and pointing outward.

STEP 2 Adjust the dial indicator to read zero.

STEP 3 Rotate the crankshaft while watching the indicator reading.

STEP 4 Any variation in reading is the amount of bore runout.

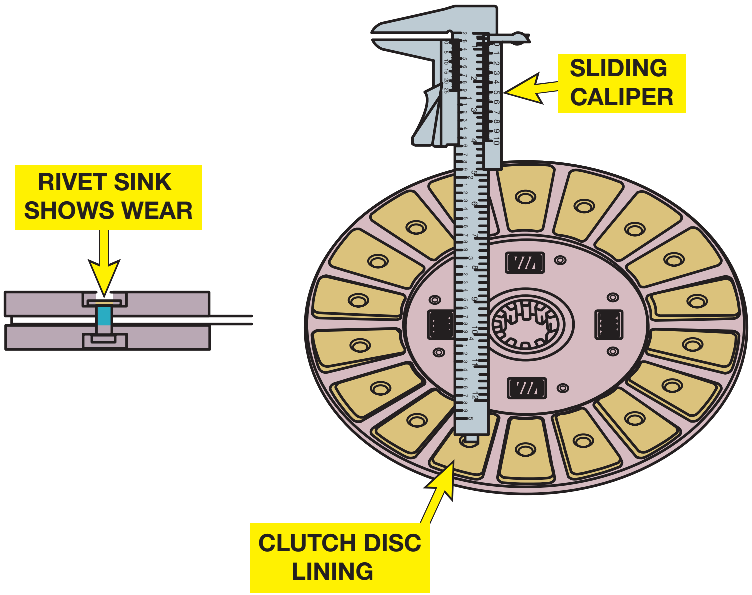

FIGURE 121–25 The overall disc thickness can be measured using a vernier caliper by first compressing the marcel spring using pliers.

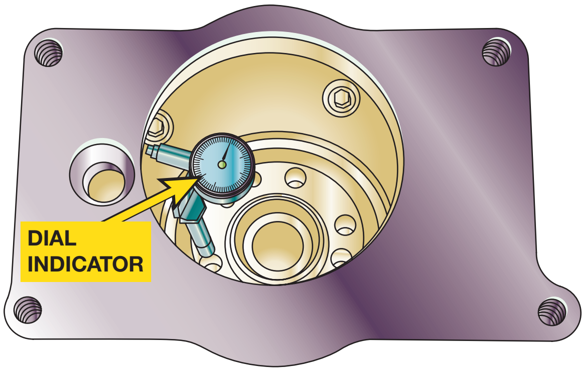

FIGURE 121–26 The dial indicator has a lever added to check clutch housing bore runout. Excessive runout can be caused by damaged or missing dowels in the engine block. If the dowels are okay, excessive runout can be corrected by installing eccentric dowels.

If the runout cannot be corrected, the bell housing is usually replaced, but it is possible to put shims between the bell housing and the engine block to correct excessive runout. The limit for bore runout is about 0.010 inch (0.25 mm). Bore runout can be corrected by using eccentric dowel pins to reposition the bell housing. These are available in different sizes. Position the bell housing so it is centered with the crankshaft. ● **SEE FIGURE 121–26**.

RELEASE BEARING INSPECTION Other than feeling for roughness or seeing obvious wear or discoloration, there are no effective bench checks for **release bearings**. This is one reason why they are normally replaced with the disc and pressure plate.

CLUTCH ASSEMBLY REPLACEMENT To replace a clutch assembly, perform the following steps:

STEP 1 Check the flywheel bolts to make sure that they are tight and torqued to specifications.

STEP 2 Check the pilot bearing recess to ensure that it is clean, and drive the new pilot bearing into place. The best tool for this is a commercial or shop-made driver with a stem the same size as the bearing bore and a face that is larger than the diameter of the bearing. The new pilot bearing is driven in until it is fully seated or has entered completely into the crankshaft. Most pilot bearings do not require lubrication. Roller bearings with exposed rollers should be lubricated with a thin film of grease or a few drops of engine oil is all that is needed on a sintered bushing.

STEP 3 Place the new clutch disc over the transmission clutch shaft and make sure that it slides freely over the splines. Determine which side of the disc goes against the flywheel which will often be marked *flywheel side*. If not marked, the damper assembly normally faces the pressure plate.

NOTE: To determine the correct clutch disc position, place each side of the disc against the flywheel and rotate it. The side that contacts the flywheel bolts or does not let the clutch facing contact the flywheel is the wrong side.

STEP 4 Position the **disc alignment** tool or an old transmission shaft or a plastic dummy transmission shaft through the disc and into the pilot bearing to center the disc.

STEP 5 Install the pressure plate over the disc, making sure that it is properly aligned with the dowel pins and mounting bolt holes, and install the mounting bolts.

CAUTION: Use only the bolts that were used originally or if replacement bolts are used, be sure that they are grade 8 (high tensile strength) fasteners.

STEP 6 Tighten the mounting bolts two turns at a time alternating back and forth across the pressure plate. Tighten the bolts to the correct torque.

STEP 7 Remove the alignment device and check to make sure that the pilot bearing is in the exact center of the disc. The height variation of the release levers can be checked after the pressure plate is installed. Using a vernier or dial caliper, measure from the contact face for the release bearing to the clutch disc. All of the heights should be within 0.020 inch (0.5 mm). The readings will be more accurate after the clutch has been applied a few times.

STEP 8 Check the clutch linkage to make sure that it operates smoothly. On cable-operated clutches, this is a good time to remove, clean, and lubricate the cable.

STEP 9 Fill the groove inside the bore of the release bearing with grease, apply a thin film of the specified high-temperature grease on the fork contact areas, and slide the release bearing onto the transmission quill, making sure that the bearing collar slides smoothly. The quill portion of the transmission bearing retainer should be smooth and unworn. On clutch forks that use pivot balls, a thin film of grease should be put on the ball. On forks mounted on pivot shafts, the pivot bushings should be lubricated.

STEP 10 Replace the transmission/transaxle, being sure to observe the following:

- Place a very thin film of grease on the clutch splines.
- Never let the transmission hang on the clutch disc splines.
- The transmission should be completely seated against the clutch housing or engine before the mounting bolts are tightened.
- Tighten the transmission mounting bolts two turns at a time, working back and forth across the transmission until they are tightened to the correct torque. It should not be necessary to force the transmission into place.
- Adjust the free travel before operating the clutch.

HYDRAULIC CLUTCH BLEEDING In many cases, a clutch hydraulic system can be bled by **gravity bleeding**, while in others, a helper may be needed. To bleed a clutch hydraulic system using the gravity method, perform the following steps:

STEP 1 Clean the bleeder valve at the actuator cylinder and place a shop cloth under it to catch escaping fluid. ● **SEE FIGURE 121–27**.

STEP 2 Open the bleeder valve by loosening the bleeder screw and observe the flow. If no flow occurs, have a helper depress the clutch pedal in a smooth, slow manner. Air bubbles coming from the bleed valve indicate that the system needed bleeding. After the air bubbles stop and a constant flow of fluid occurs, close the bleed valve. An alternative method is reverse, or back-bleeding. This is done by forcing fluid through the actuator cylinder bleed valve and upward to the reservoir.

STEP 3 Check the fluid level and correct it, if necessary.

Some master and actuator cylinders are mounted so that the cylinder portion is above the line connection, which makes it extremely difficult to bleed air from them.

- In some cases, it is possible to bench bleed them to remove all the air before installing on the vehicle. An alternative bleeding method is to have a helper partially apply the clutch while reverse bleeding using pressure surges from the fluid injector.
- Some clutch hydraulic systems will partially self-bleed if the clutch pedal is held completely depressed overnight using a brake pedal depressing tool.
- Another bleeding method is to construct an adapter to the fluid reservoir so a vacuum can be applied to the fluid using a hand, electric, or air-powered vacuum pump. Reducing the air pressure on the fluid will cause the air bubble to expand and move upward to the reservoir.

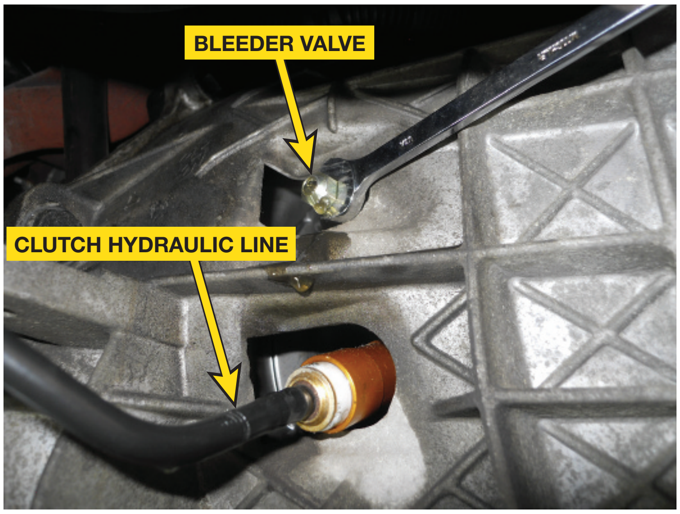

FIGURE 121–27 Gravity bleeding a hydraulic clutch. Opening the bleeder valve should allow air to escape and then fluid should flow.

REVIEW QUESTIONS

1. What parts are included in a typical clutch assembly?
2. What happens when the driver depresses the clutch pedal?
3. Why is a dual-mass flywheel used on some vehicles?
4. What parts are normally replaced as part of a clutch job?
5. What should be lubricated during clutch replacement?

CHAPTER QUIZ

1. Which part does *not* rotate when the engine is running and the clutch pedal is depressed?
  a. Pilot bearing (bushing)
  b. Pressure plate
  c. Input shaft
  d. Flywheel

2. A clutch disc is being installed. Technician A says the damper assembly of the clutch disc normally faces the pressure plate. Technician B says that the disc splines should be lightly lubricated. Which technician is correct?
  a. Technician A only
  b. Technician B only
  c. Both Technicians A and B
  d. Neither Technician A nor B

3. A dual-mass flywheel is used to ______________.
  a. reduce clutch effort
  b. reduce vibration
  c. increase torque holding ability of a clutch
  d. decrease vehicle weight

4. Most hydraulic clutch systems use what hydraulic fluid?
  a. DOT 3 brake fluid
  b. Mineral (hydraulic) oil
  c. SAE 80W-90 gear oil
  d. ATF

5. Flywheels are constructed of cast iron because ______________.
  a. they contain about 3% carbon, which acts as a lubricant for the clutch
  b. they have a lot of inertia
  c. they can be resurfaced
  d. All of the above

6. The most commonly used clutch linkage is ______________.
  a. mechanical (rods and levers)
  b. hydraulic
  c. cable
  d. electrically controlled

7. The release bearing sleeve slides on the outer surface of a tube, which is commonly called the ______________.
  a. quill
  b. quill shaft
  c. candlestick
  d. Any of the above

8. A clutch switch is used to ______________.
  a. disengage the clutch
  b. engage the clutch
  c. prevent the engine from starting unless the clutch pedal is depressed
  d. provide an input signal for the PCM to disengage the clutch

9. Springs are mounted at the center of a clutch disc. Technician A says they help cushion clutch engagement. Technician B says they absorb engine torsional vibrations. Which technician is correct?
  a. Technician A only
  b. Technician B only
  c. Both Technicians A and B
  d. Neither Technician A nor B

10. When the clutch is disengaged (clutch pedal down) ______________.
  a. springs force the pressure ring toward the clutch cover
  b. springs force the pressure ring toward the flywheel
  c. the release (throwout) bearing is used to move the pressure ring toward the clutch cover
  d. the pilot bearing is pressed toward the engine

MANUAL TRANSMISSIONS/ TRANSAXLES

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Discuss the need for a transmission.
- Explain the different types of gears.
- Discuss gear ratios.
- Describe the relationship between torque, speed, and power.
- Describe the construction of a transmission/transaxle.
- Describe speed gears.
- Explain the construction and operation of a synchronizer.
- Describe the torque flow through a five-speed manual transmission.
- Describe the procedure to diagnose, remove, disassemble, assemble, and install a manual transmission/transaxle.
- Discuss manual transmission/transaxle lubricants.

THE NEED FOR A TRANSMISSION

A vehicle requires a lot of torque to start off and to climb hills, yet it does not require as much torque to move on level ground. The source of the torque is the engine. Torque is a twisting or turning force that is exerted on the input shaft of a transmission/transaxle. An engine produces increasing torque as its speed increases up to a certain point where the torque output starts to decrease. Therefore, to get a vehicle moving or to accelerate up a hill, it is desirable to use a transmission that allows the engine speed to be increased even though the vehicle speed may be low. Using gears allows the engine speed to increase at low vehicle speeds yet still permits the engine speed to drop at higher speeds to save fuel and reduce exhaust emissions.

For example,

- First gear: Vehicle speed is low, engine speed is high.
- Second gear: Vehicle speed increases, engine speed decreases as shift is made.
- Third gear: Vehicle speed continues to increase, engine speed is kept in a narrow range.
- Fourth gear: Again, the vehicle speed is increasing, yet engine speed is about the same as in third gear.

GEAR TYPES

The simplest type of gear is the **spur gear**. ● **SEE FIGURE 122–1**. A spur gear consists of a gear blank with straight-cut teeth around its entire circumference. All gear teeth lie parallel to the centerline, or **axis**, of the gear. The teeth are shaped so they can mesh without slippage with a second spur gear's teeth positioned along a parallel axis.

Spur gear design permits 1.5 to 2.5 gear teeth to mesh at a time. The gear teeth make contact with each other over their full width at the same instant. The fact that the gear teeth are in full contact increases the strength of the gear, but also causes spur gear operation to be noisy. Due to their strength, most heavy-duty truck transmissions use spur gears.

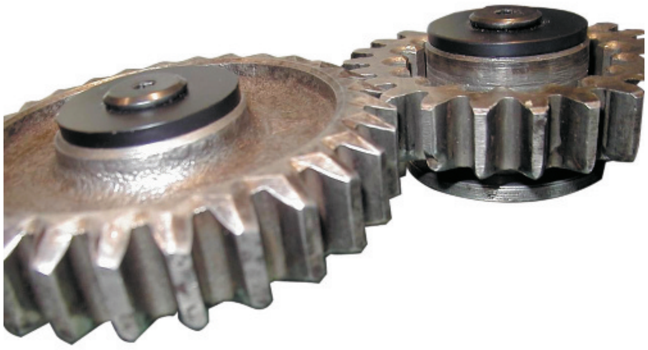

FIGURE 122–1 Spur gears have straight-cut teeth.

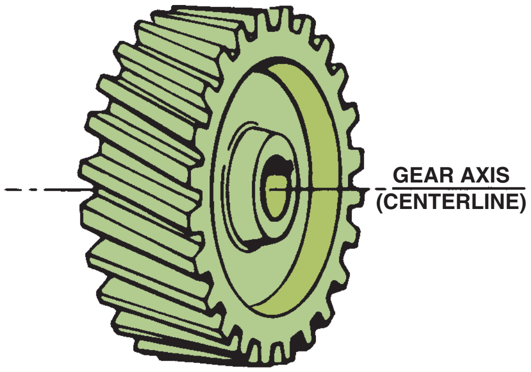

FIGURE 122–2 The teeth of a helical gear are cut at an angle to the gear axis.

A **helical gear**, although similar to a spur gear, has its teeth cut at an angle to the axis of the gear. ● **SEE FIGURE 122–2**. This enables more teeth, 2.5 to 3.5, to mesh at a time than the spur gear. Additionally, the angle allows the teeth to mesh gradually, rather than all at once. As a result, helical gears run quieter than spur gears. Helical gears, however, have two disadvantages. Each gear pushes against its shaft parallel to its axis. Special bearings are needed to protect the gearbox from this type of axial, or thrust, loading. Furthermore, because of the increased contact area, helical gears create more friction than spur gears. ● **SEE FIGURE 122–3**.

Spur and helical gears have gear teeth on their outside circumference and, for this reason, are called **external gears**. This type of gear is the most commonly used in manual transmissions and transaxles.

Gears having teeth along the inside circumference are called **internal ring gears**. ● **SEE FIGURE 122–4**. The teeth of an internal ring gear may be spur or helical teeth. An internal ring gear may mesh with a smaller external gear designed to rotate as it travels around the inside of the internal ring gear. This type of external gear is called a **pinion gear** because of its smaller diameter.

FREQUENTLY ASKED QUESTION

What Is the Difference between a Transmission and a Transaxle?

A transmission is used on rear-wheel-drive vehicles, whereas a transaxle is usually used on front-wheel-drive vehicles. A vehicle equipped with a transmission uses a separate differential to split the torque equally to the drive wheels. A transaxle includes a differential assembly. In a transaxle, the differential, sometimes called the *final drive unit,* is incorporated in the construction of the transmission.

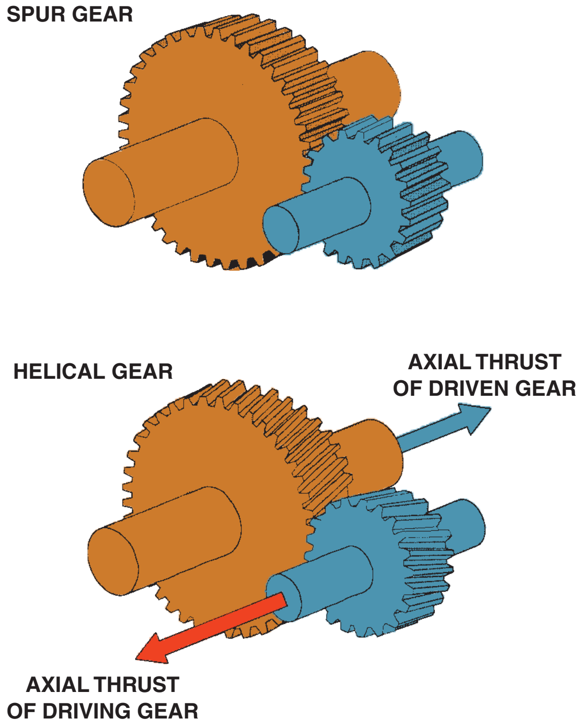

FIGURE 122–3 A spur gear has straight-cut teeth. This design is very strong and is used where strength is important. Spur gears are noisy during operation. Helical-cut gears, on the other hand, operate quietly but create a force in line with the axis of the gears due to the angle of the gear teeth.

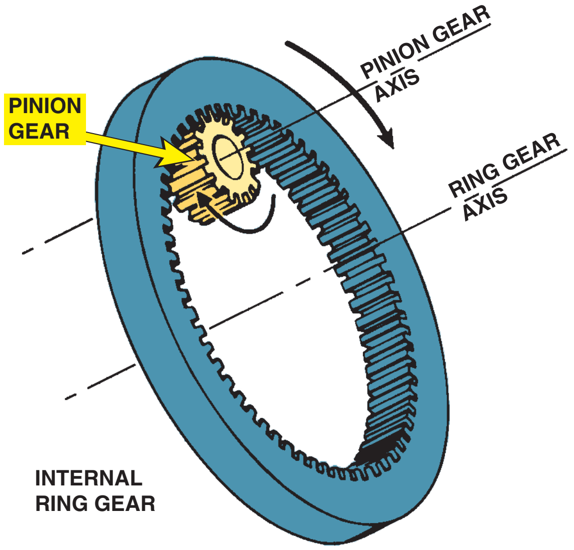

FIGURE 122–4 A pinion gear meshed with an internal ring gear rotates in the same direction around a parallel axis of rotation.

When an external gear meshes with an internal ring gear, both gears rotate in the same direction, but when an external gear meshes with another external gear, the gears rotate in opposite directions as shown in ● **SEE FIGURE 122–5**.

BEVEL GEARS The teeth of a **bevel gear** are cut at an angle to the outside gear surface. Simple bevel gears have straight-cut teeth similar to those on a spur gear. ● **SEE FIGURE 122–6**.

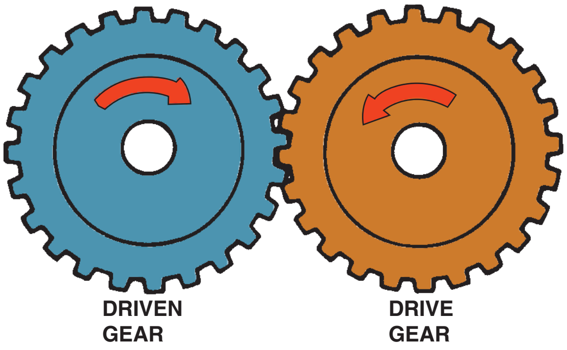

FIGURE 122–5 When two external gears mesh, they rotate in opposite directions.

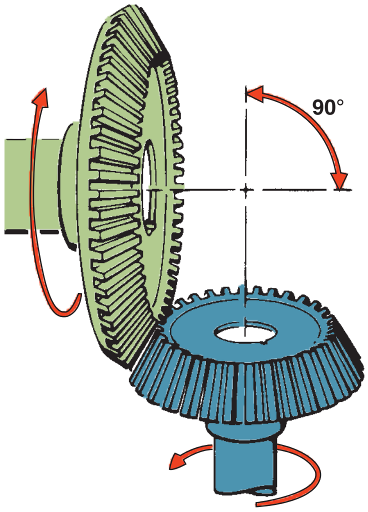

FIGURE 122–6 Bevel gears are often used to change the direction of rotation and are typically used in differentials.

Special gears used in a differential, called spider gears, are a common example of the simple bevel gear.

GEAR RATIOS

When one gear turns another, the speed that the two gears turn in relation to each other is the gear ratio. Gear ratio is expressed as the number of rotations the **drive gear** must make in order to rotate the **driven gear** through one revolution. To obtain a gear ratio, simply divide the number of teeth on the driven gear by the number of teeth on the drive gear. Gear ratios, which are expressed relative to the number one, fall into three categories:

- Direct drive
- Gear reduction
- Overdrive

A gear ratio is determined by dividing the number of teeth on the driven gear (output) by the number of teeth on the driving gear (input). ● **SEE FIGURE 122–7**.

$$\frac{\textbf{Number of teeth on the driven gear (24)}}{\textbf{Number of teeth on the driving gear (12)}} = \textbf{2:1}$$

The gear ratio represents the number of turns of the input gear to one turn of the output gear. A transmission/transaxle usually uses two pairs of gears to achieve each gear ratio, and there may be four, five, or six forward gears plus reverse. When two pairs of gears are used to create a gear, simply multiply the two ratios together to get the gear ratio.

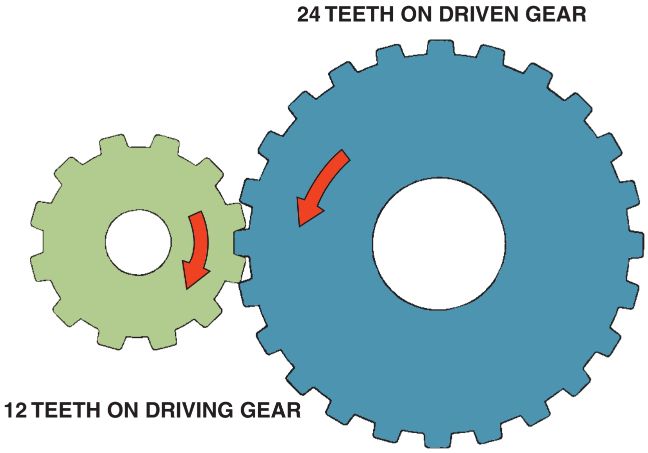

FIGURE 122–7 Gear ratio is determined by dividing the number of teeth of the driven (output) gear (24 teeth) by the number of teeth on the driving (input) gear (12 teeth). The ratio illustrated is 2:1.

A low first-gear (high numerical) ratio creates a high amount of torque applied to the drive wheels to get the vehicle moving. To summarize what is occurring if the engine speed is constant:

First gear:

- Output shaft speed is a lot lower than engine speed.
- Output torque is a lot higher than the engine is producing.

Fifth gear:

- Output shaft speed is faster than the engine speed.
- Output torque is lower than the engine is producing.

DIRECT DRIVE

If two meshed gears are the same size and have the same number of teeth, they will turn at the same speed. Since the drive gear turns once for each revolution of the driven gear, the gear ratio is 1:1; this is called a **direct drive**. When a transmission is in direct drive, the engine and transmission turn at the same speed.

GEAR REDUCTION

If one gear drives a second gear that has three times the number of teeth, the smaller drive gear must travel three complete revolutions in order to drive the larger gear through one rotation. ● **SEE FIGURE 122–8**. Divide the number of teeth on the driven gear by the number of teeth on the drive gear and you get a 3:1 gear ratio (pronounced three to one). This type of gear arrangement, where driven gear speed is slower than drive gear speed, provides **gear reduction**. Gear reduction may also be called underdrive as drive speed is less than, or under, driven speed. Both terms mean the same thing and use is a matter of preference.

Gear reduction is used for the lower gears in a transmission. First gear in a transmission is called "low" gear because output speed, not gear ratio, is low. Low gears have numerically high gear ratios. That is, a 3:1 gear ratio is a lower gear than those with a 2:1 or 1:1 gear ratio. These three ratios taken in order represent a typical upshift pattern from low gear (3:1), to second gear (2:1), to third gear (1:1).

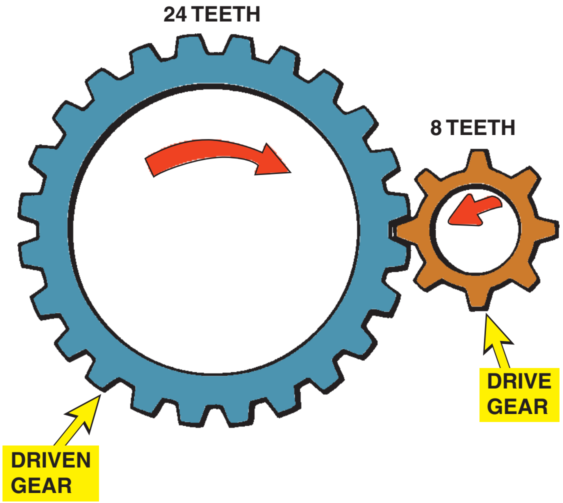

FIGURE 122–8 This gear combination provides a gear reduction of 3:1.

OVERDRIVE **Overdrive** is the opposite of a gear reduction condition and occurs when a driven gear turns faster than its drive gear. For the gears shown in ● **FIGURE 122–9**, the driven gear turns three times for each turn of the drive gear. The driven gear is said to overdrive the drive gear. For this example, the gear ratio is 0.33:1. Overdrive ratios of 0.65:1 and 0.70:1 are typical of those used in automotive applications.

NOTE: Ratios always end in one with a colon in between. Therefore, the first number is less than one if it is an overdrive ratio and greater than one if it is a gear reduction ratio.

IDLER GEARS A gear that operates between the drive and driven gears is called a floating gear, or idler gear. ● **SEE FIGURE 122–10**. Idler gears do not affect the speed relationship between the drive and driven gears, although they do affect the direction of rotation. Reverse gear on a manual transmission often uses an idler gear to change the direction of rotation.

When a drive and driven gear mesh directly, they rotate in opposite directions. When an idler gear is installed between the drive and driven gears, both drive and driven gears rotate in the same direction.

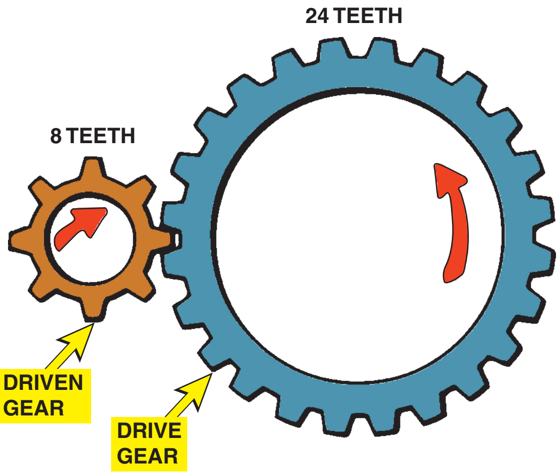

FIGURE 122–9 This gear combination provides an overdrive ratio of 0.33:1.

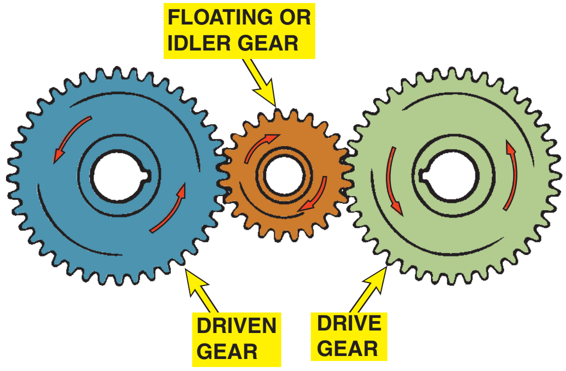

FIGURE 122–10 Idler gears affect the direction of rotation in a gear train, but not the final drive ratio.

TORQUE, SPEED, AND POWER

Torque is a twisting force commonly expressed in pound-feet (lb-ft) or Newton-meters (N-m). Gears apply torque much like a wrench does; each tooth of a gear is actually a lever. On a gear with a 2-foot radius, applying a force of 10 pounds to one gear tooth exerts 20 lb-ft of torque on the center of the shaft to which the gear attaches. ● **SEE FIGURE 122–11**.

TORQUE AND SPEED RELATIONSHIP Torque and speed have an inverse relationship: as one goes up, the other goes down. With a constant input speed, transmission torque decreases as output speed increases. The opposite also applies assuming a constant input speed, transmission torque increases as output speed decreases.

TORQUE MULTIPLICATION Levers can be used to increase or multiply torque. For example, a wheel that is too heavy for a person to turn by muscle power alone turns easily when that same person uses a lever and fulcrum to multiply the applied force. ● **SEE FIGURE 122–12**. The force, or torque, increases at one end, but the lever must be moved a greater distance at the opposite end to obtain the increase in force. Either distance or speed must always be given up in order to increase, or multiply, torque.

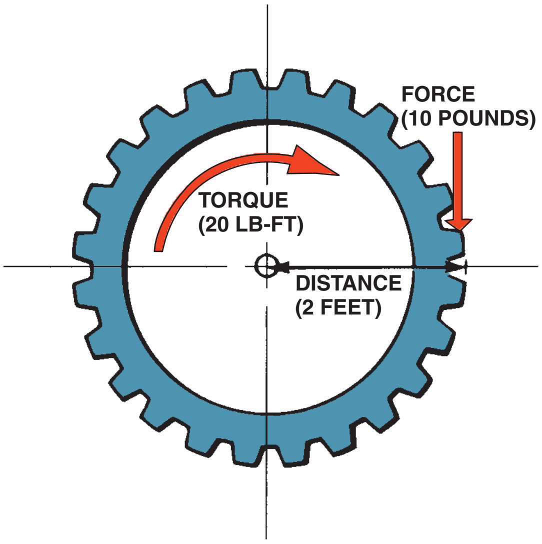

FIGURE 122–11 Gears apply torque in the same way a wrench applies torque—the force applied multiplied by the distance from the center of the gear equals the torque.

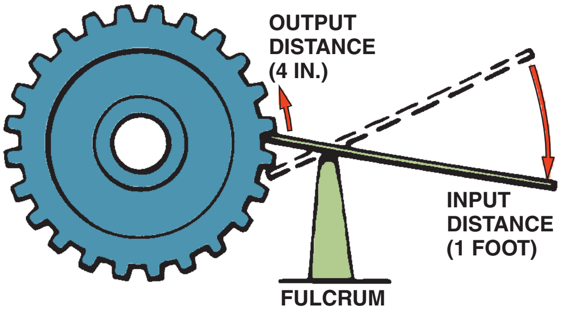

FIGURE 122–12 A lever can be used to multiply torque, but it does so at the expense of distance or speed.

When two gears of the same diameter are meshed, the driven gear will turn at the same speed as the drive gear. Since there is no difference in speed, there is no difference in torque between the two gears.

If the drive gear is one-third the diameter of the driven gear, it must rotate three times for each rotation of the larger gear. This means that the larger gear will turn three times slower than the smaller gear. At the same time, the larger gear will exert three times the torque of the smaller gear. When speed decreases, torque increases. Torque multiplication and gear ratios are directly related. When a gear system is in reduction, there is more torque available at the driven gear, but less speed. When the gear system is in overdrive, there is less torque available at the driven gear, but greater speed.

ENGINE TORQUE CHARACTERISTICS The torque curve of an engine shows how much torque is available at different points within a range of engine speeds.

Because of these characteristics, torque multiplication must be provided between the crankshaft and drive axles to enable a vehicle to begin moving from a standstill and to accelerate at low speeds. Once engine RPM rises beyond the torque peak, a change in gear ratio brings engine speed back within the most efficient torque producing range.

TRANSMISSION CONSTRUCTION

A transmission is usually constructed of cast aluminum machined to accept the internal parts and strong enough to be a structural member of the drive train. The front of the transmission attaches to a separate **bell housing** or includes the bell housing as part of the casting of the transmission itself. At the front of the transmission (toward the engine) is the **front bearing retainer** (sometimes called the **quill**) that supports the clutch throwout (release) bearing and usually houses the front grease seal. The rear of the transmission usually includes a separate casting called the **extension housing**. The center housing is usually referred to as the **transmission case**. ● **SEE FIGURE 122–13**.

The **input shaft** is splined to the clutch disc and is also referred to as the **main gear**, **clutch gear**, or **main drive pinion assembly**. The **main shaft**, also called the **output shaft**, is splined at the end and transmits engine torque to the drive shaft (propeller shaft) through a yoke and universal shaft.

All manual transmissions/transaxles use a **countershaft** (also called a **lay shaft** or **cluster shaft**) to provide the other set of gears necessary to achieve the changes in gear ratios. The gears on the countershaft are called **cluster gears** or **counter gears**.

FREQUENTLY ASKED QUESTION

What Is Meant by a 77 mm Transmission?

The size (77 mm or about 3 inches) is the distance between the center of the input shaft and the center of the countershaft. The greater this distance, the larger the transmission and the more torque it is capable of handling due to the larger gears. ● **SEE FIGURE 122–14**.

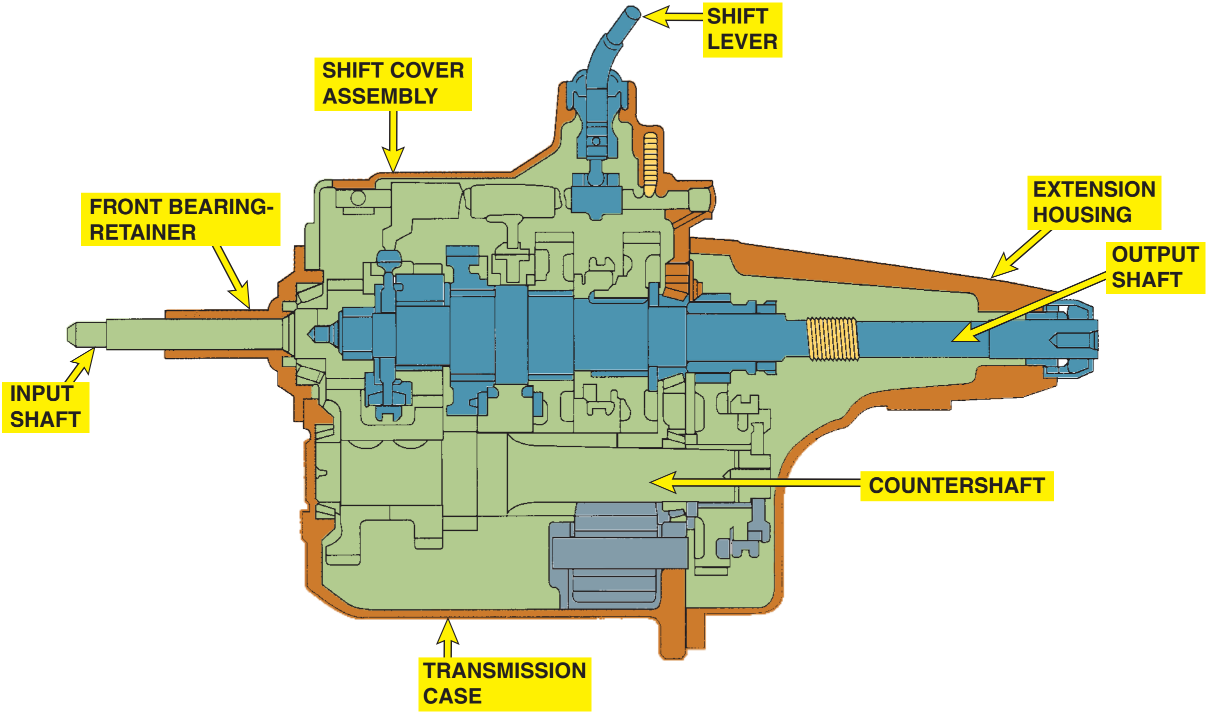

FIGURE 122–13 Cross section of a five-speed manual transmission showing the main parts.

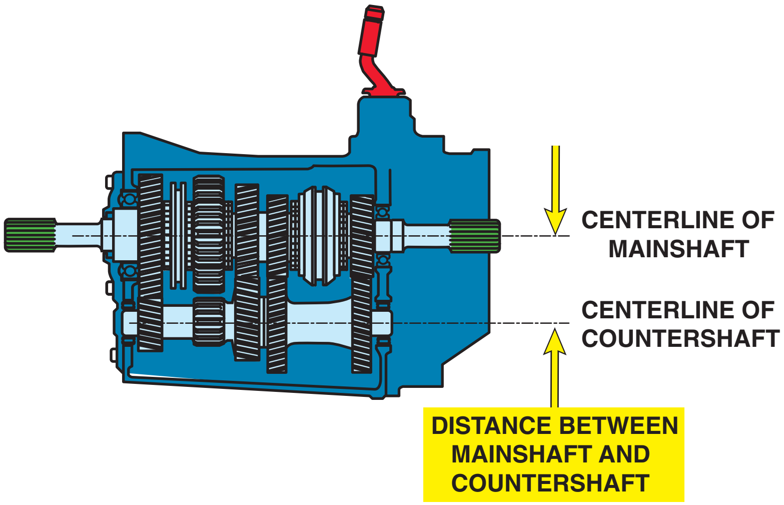

CENTERLINE OF MAINSHAFT
CENTERLINE OF COUNTERSHAFT
DISTANCE BETWEEN MAINSHAFT AND COUNTERSHAFT

FIGURE 122–14 The torque capacity of a transmission is determined by the size of the gear and bearings used. The greater the distance, usually measured in millimeters such as 77 mm, between the main shaft and the countershaft, the greater the torque capacity.

TORQUE FLOW THROUGH A MANUAL TRANSMISSION The engine torque is applied to the input shaft when the clutch is engaged (clutch pedal up). This torque is applied to the main gear, which is in constant mesh with the countershaft gear.

HINT: The fact that the countershaft is revolving any time the clutch is engaged makes transmission noise diagnosis easier.

The engine torque is multiplied by the ratio difference between the main gear and the cluster gear. The engine torque is then transferred and multiplied again when first gear is in mesh with the corresponding first gear on the main (output) shaft. Again, the torque is multiplied by the ratio difference between the two gears. The engine torque then is applied to the drive wheels through the driveshaft, differential, and drive axles.

SPEED GEARS

All gears on the countershaft are permanently attached to the shaft. When the countershaft rotates, all gears on the countershaft rotate. The input shaft gear is also part of the input shaft. However, the gears on the main shaft are free to move on the shaft and are connected to the main shaft through the synchronizer hub when a shift is made. The gears that rotate on the main shaft are called *speed gears* and are free to rotate on a film of oil or on bearings.

HINT: When assembling the main shaft and the countershaft, just remember that each shaft should look like a fir tree (tapered downward from the top). When installed in the transmission, these two "fir trees" are meshed together with the small gear end of one shaft meshing with the large gear end of the other shaft. ● **SEE FIGURE 122–15.**

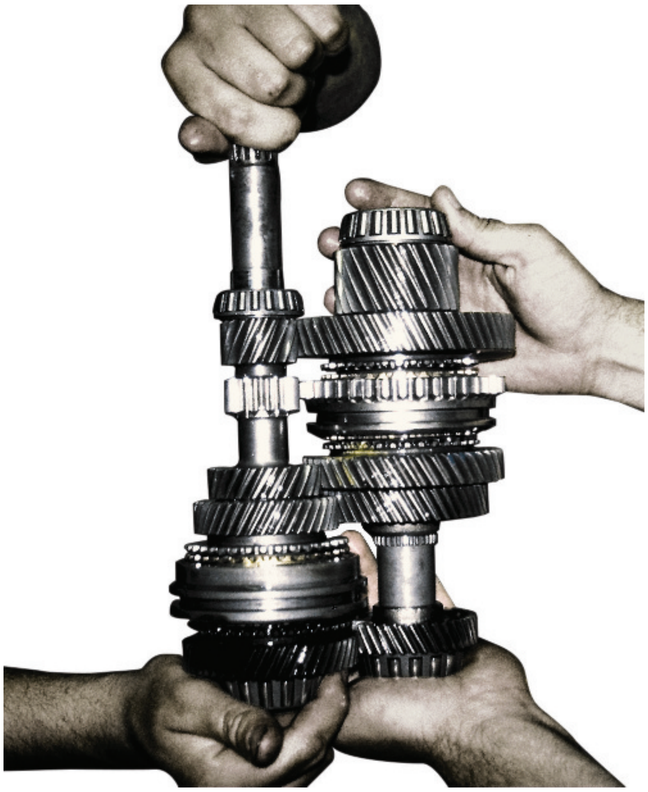

FIGURE 122–15 Notice that the countershaft and the main shaft both use gears of increasing size that mesh together.

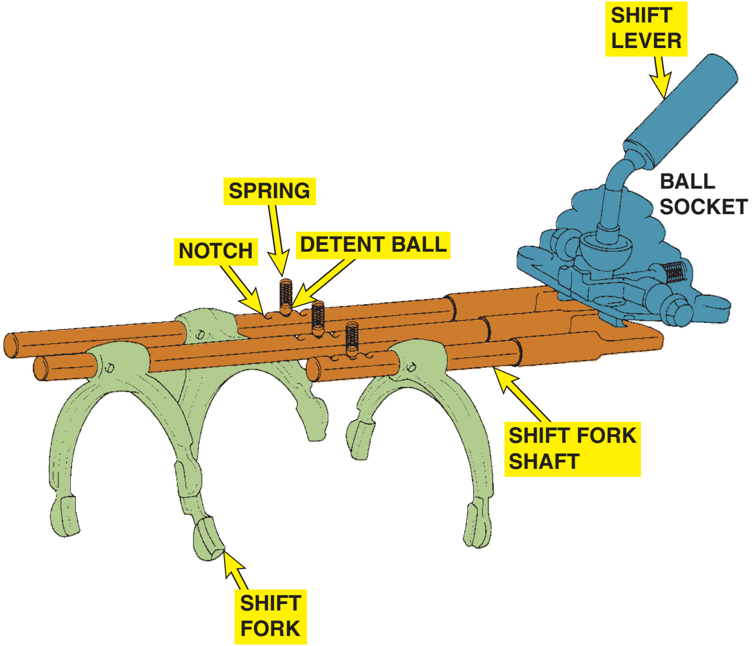

FIGURE 122–16 A typical shift mechanism is designed to not only give the driver a solid feel when shifting, but also prevents shifting into reverse except from the neutral position.

SYNCHRONIZER PARTS AND OPERATION

Most vehicles today in a manually shifted transmission use a floor-mounted shifter to change gears. The shifting lever either moves cables that transfer the shifting motion to the transmission or transaxle or move the shift forks directly. Inside the transmission/transaxle are shift forks that control shifts between two gears, such as first and second or second and third. Interlocks either in the shifter linkage itself or inside the transmission/transaxle prevent the accidental selection of reverse except when shifting from neutral and also prevent selecting two gears at the same time. ● **SEE FIGURE 122–16.**

Synchronizers are used in manual transmissions/transaxles to make shifting easier. To synchronize means to make two or more events occur at the same time. When the driver depresses the clutch pedal, torque is no longer being transmitted to the input shaft and the drive wheels are "driving" the main shaft of the transmission/ transaxle. To achieve a clash-free (no grinding sound) shift, the two gears to be meshed must be rotating at the same speed. The detents and interlocks hold the shift mechanism in position.

The real "shifting" in a synchromesh transmission takes place in the **synchronizer assemblies**, not the gears. Most synchronizer assemblies ride on the output shaft between two gears. A synchronizer assembly is named for the gears on either side of it, which are the two speeds that it engages. For example, a five-speed transmission with constant-mesh reverse uses a 1–2 synchronizer, 3–4 synchronizer, and a 5-reverse synchronizer.

SYNCHRONIZER CONSTRUCTION Although there are a number of design variations, all are similar and include a hub, a **sliding sleeve**, a **blocker ring** (or **stop ring** or **synchronizer ring**), **keys**, and **springs**. In addition, the tapered cone and coupling teeth machined on the speed gear are part of the synchronizer assembly. ● **SEE FIGURE 122–17**. In a typical synchronizer:

- Splines attach the center **hub** of the synchronizer to the output shaft, so the hub and output shaft rotate together. There are also splines machined on the outer circumference of the hub.
- An outer sliding sleeve rides on the external hub splines with enough clearance so that it slides freely. The splines on the sleeve also match the small coupling teeth of the stop ring and speed gear. Coupling teeth are also called engagement or clutch teeth. The sleeve is splined to the hub, so it rotates with the output shaft.
- A **stop ring** sits between the speed gear and the sleeve. The coupling teeth on the stop ring match those on both the sleeve and the speed gear. The stop ring also has a tapered cone to match the cone machined on the speed gear.
- Small, spring-loaded detent keys, also called **synchronizer keys** or **struts,** ride in slots on the outer sleeve. The stop ring has slots to match these keys. This allows the stop ring to rotate slightly, relative to the sleeve, before the keys hit the sides of their slots and stop the stop ring. As the sleeve moves, the synchronizer keys move with it, which pushes the blocking ring onto the tapered cone of the speed gear.

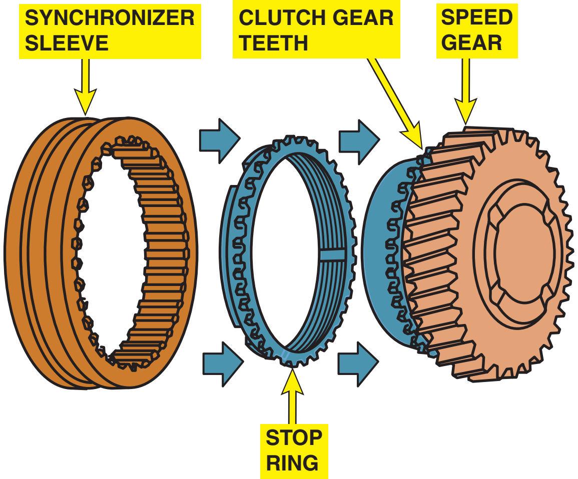

FIGURE 122–17 The shifter fork fits into the groove of the synchronizer sleeve. When a shift is made, the sleeve is moved toward the speed gear. The sleeve presses the stop ring (synchronizer ring) against the cone area of the speed gear. The friction between the stop ring and the speed gear causes the speed of the two to become equal, permitting the sleeve to engage the gear clutch teeth of the speed gear. When this engagement occurs, the shift is complete.

SYNCHRONIZER OPERATION When the outer sliding sleeve is centered on the hub, the synchronizer is in its neutral position—it does not contact either of the speed gears. ● **SEE FIGURE 122–18**. To shift into gear, the driver disengages the clutch and moves the shift linkage. The shift linkage, which is described later in this chapter, pushes the sleeve toward one of the speed gears. As the sleeve moves, the detent keys help guide the stop ring toward the speed gear. This causes the ring cone to slide onto the tapered cone of the speed gear.

The speed gear is turning because it is in constant mesh with a countershaft gear. However, the gear may not be turning at the same speed as the synchronizer assembly even though both are on the same shaft. When the clutch is disengaged, the engine is no longer driving the transmission, so there is no torque applied to the input shaft, and the countershaft, or cluster gear, simply freewheels. As the shift is made, the stop ring acts as a brake to slow down the gear so that its speed matches the speed of the synchronizer assembly. That is, it synchronizes the shift. This matched speed allows the internal hub splines to easily engage the coupling teeth on the stop ring and speed gear. When the clutch disengages, the crankshaft drives the input shaft, which drives the countershaft, which drives the output shaft through the selected gear.

The synchronizer goes through three stages during a shift:

1. As the shift is selected, the sliding sleeve moves toward the speed gear. If the speeds of the sliding sleeve (main shaft) and the speed gear (counter shaft) are not identical, the speed difference will cause the tapered cone to "mis-align" the teeth of the sleeve, the stop ring, and the speed gear. This "blocks" the shift. Now, the tapered teeth of the sliding sleeve push against the teeth of the stop ring, which in turn pushes the stop ring tapered surface up against the tapered surface of the speed gear. This causes the speed gear to either speed up or slow down based on the difference between the main shaft speed (hub) and the counter gear speed (speed gear). When the speeds are equal, the

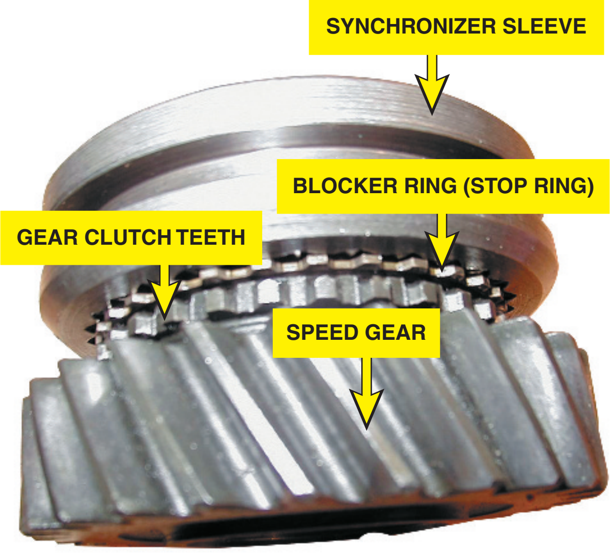

FIGURE 122–18 Typical synchronizer assembly.

thrust is released on the tapered surface, which now allows the "alignment" of the sliding sleeve teeth, the stop ring teeth, and the speed gear teeth that allows the shift to be completed. ● **SEE FIGURE 122–19**.

2. The sleeve overcomes the force of the detent key springs as the shift linkage continues to move it toward the gear. This allows the stop ring to relax and move slightly so that the sleeve splines begin to engage the coupling teeth on the stop ring. At this point, the coupling teeth on the stop ring and the speed gear may not line up with each other. However, friction continues to build between the ring and the cone, so the gear continues to slow down.
3. Once the sleeve, stop ring, and gear are all turning at the same speed, it takes just a small movement between the stop ring and gear to align the coupling teeth and allow the sleeve to slip completely over both sets. The speed gear is now locked to the output shaft through the synchronizer stop ring and sleeve. ● **SEE FIGURE 122–20**.

Synchronizer stop rings are a simple type of clutch, called a cone clutch for the shape of the mating surfaces. Some manufacturers refer to the synchronizer action as "clutching."

Synchronizer sleeves and hubs are gear-quality steel. Stop rings are a softer metal—usually brass, copper, or a sintered metal—to absorb the friction of synchronizer operation.

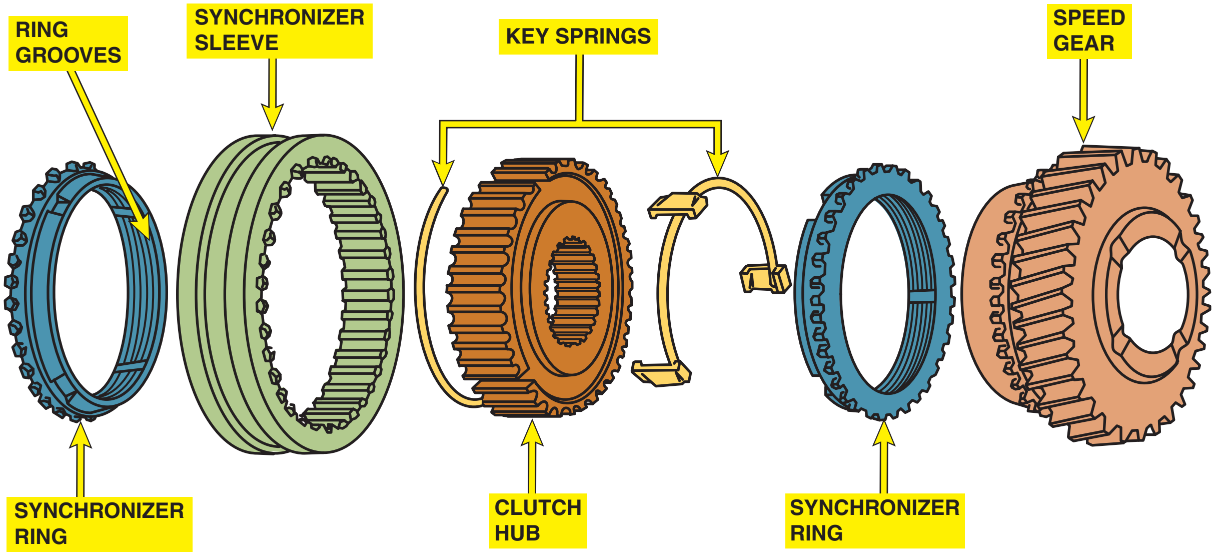

FIGURE 122–19 Synchronizer keys are attached to the clutch hub and push against the synchronizer ring when the sleeve is being moved during a shift. Notice the grooves on the synchronizer ring. These grooves prevent lubricating oil from becoming trapped between the ring and the cone surface of the speed gear. The grooves also help the ring release from the cone surface when a shift is made out of a gear.

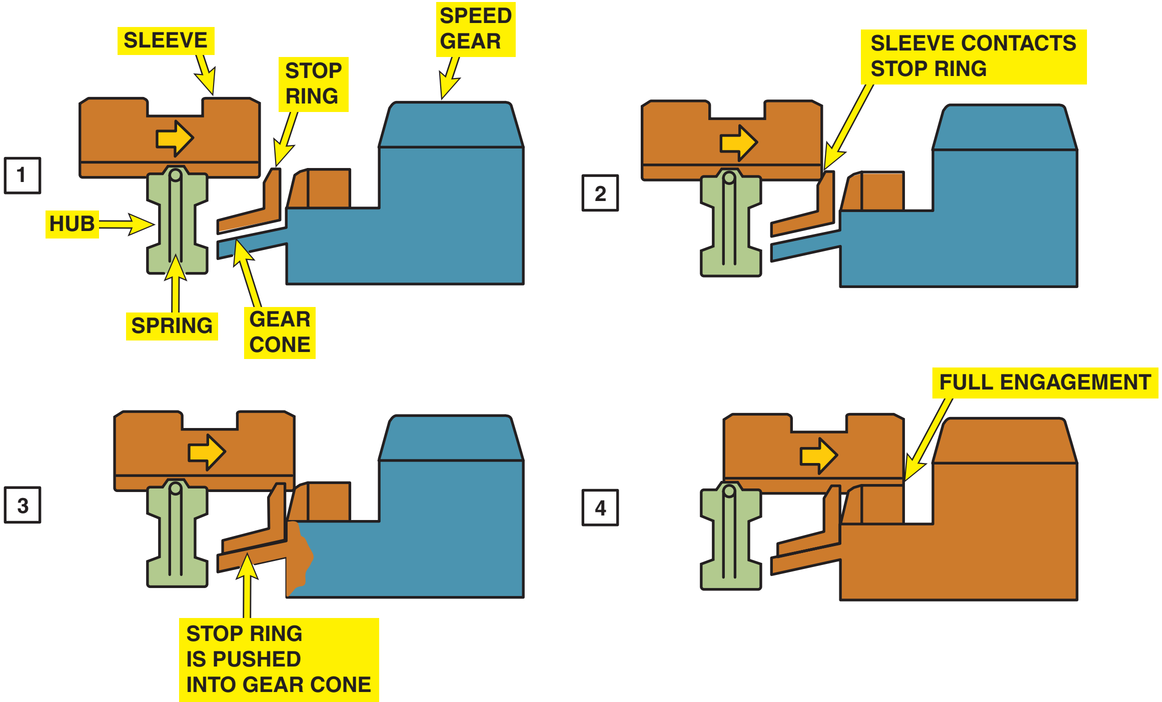

FIGURE 122–20 A shift sequence starts when the shift fork is moved by the driver, (1) applying a force on the sleeve that moves it toward the speed gear. (2) The sleeve and the inserts contact the stop ring (blocking ring). (3) The synchronizer ring (stop ring) engages the cone on the speed gear, causing both assemblies to reach the same speed. (4) The shift is completed when the internal teeth of the sleeve mesh with the gear clutch teeth of the speed gear.

FREQUENTLY ASKED QUESTION

What Do the Keys Do?

The keys are there to limit the amount of rotation of the ring from 1/2 tooth misaligned in the forward direction, to 1/2 tooth misaligned in the "coast" direction so that both upshifts and downshifts can be made. The detent key springs are designed to "push up" on the keys that have a "bump" on them that aligns with a notch in the inside center of the sliding sleeve. This upward pressure tends to keep the sliding sleeve in the neutral position and prevents unwanted movement toward another unwanted gear.

The tapered cone is relieved, that is, grooves are machined into its contact surface. These grooves serve two purposes; they

- Channel excess lubricant out from between the two pieces for better contact.
- Retain a small amount of lubricant. This decreases wear when the cone clutch must slip slightly during coupling tooth alignment.

The internal splines on the synchronizer sleeve and the coupling gear teeth on stop rings and speed gears have a special shape that works to hold the gear engaged once the driver releases the shift lever. The ends of the gear teeth are chamfered, giving them a triangular shape. These pointed ends allow easier sleeve-to-gear alignment as the angles tend to center the splines between the teeth. Once aligned, a back taper machined behind the chamfered end of the teeth and splines tends to keep the sleeve in place until the linkage pushes the sleeve away for another shift. **Back taper** is an angle cut opposite to the chamfer so that spline or tooth narrows just behind the chamfered end. ● **SEE FIGURE 122–21**. The back taper creates resistance to motion to keep the splines from sliding off the coupling teeth. This is especially important when there is no torque load, such as coasting, to help keep the parts meshed. Worn back taper may cause the transmission to jump out of gear, usually when the throttle is released.

Some synchronizer stop rings have friction material on the cone surface. This paper friction material is the same as used on automatic transmission clutch plates and provides a smoother synchronizing action than metal-to-metal contact. A manual transmission with paper stop rings must use automatic transmission fluid (ATF). Other lubricants damage the paper ring surface. ● **SEE FIGURE 122–22**.

FIGURE 122–21 Before reassembling the transmission/transaxle, carefully inspect the splines on the synchronizer sleeves for wear. The shape of the splines helps prevent the transmission/transaxle from jumping out of gear during acceleration and deceleration.

FIVE-SPEED TRANSMISSION TORQUE FLOW

FIVE-SPEED TRANSMISSION A five-speed transmission has six gear sets that provide five forward speeds and one reverse speed. Either a sliding gear or constant-mesh gears may be used for reverse. All forward gears are the constant-mesh type. The Borg-Warner T5 manual transmission serves as an example of a contemporary five-speed design. In addition to reverse, the T5 provides three gear reduction ratios (first, second, and third), direct drive (fourth), and an overdriven ratio (fifth). A sliding idler gear is used to change output shaft direction and provide reverse.

NEUTRAL In **neutral**, all of the synchronizer sleeves are centered on their hubs as shown in ● **SEE FIGURE 122–23**. Note that in this

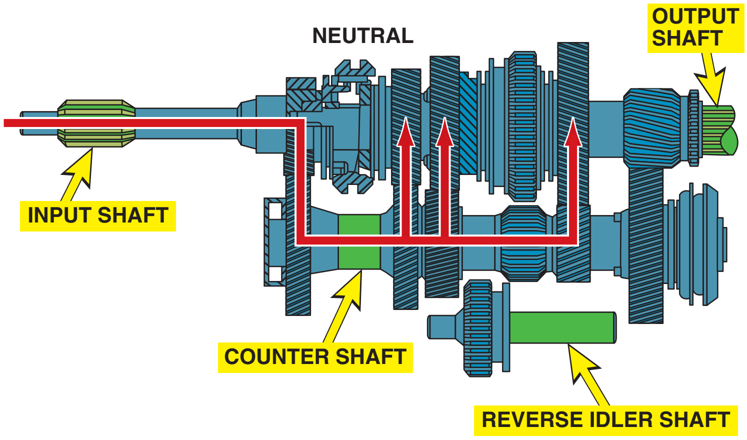

FIGURE 122–23 In neutral, the input shaft and the countershaft are rotating if the clutch is engaged (clutch pedal up), but no torque is being transmitted through the transmission.

and the following illustrations the reverse idler shaft and sliding gear have been repositioned for clarity. In actuality, the assembly is positioned so it meshes with the reverse gears of the countershaft and output shaft simultaneously.

With the clutch engaged, the drive gear of the input shaft turns the cluster gear, or countershaft. The speed gears are driven by the cluster gears, but rotate freely, on the output shaft. The output shaft may turn if the vehicle is moving or coasting, but no engine torque being transferred through the transmission.

FIRST GEAR In **first gear**, the shift linkage slides the 1–2 synchronizer sleeve rearward toward the first speed gear. ● **SEE FIGURE 122–24**. The synchronizer assembly locks the speed gear to the output shaft.

With the clutch engaged, the input shaft drives the countershaft, delivering engine torque to the gearbox. Torque transfers from the first counter gear to the first speed gear, which drives the output shaft through the 1–2 synchronizer hub splines. Torque flows through the transmission in gear reduction at the first gear ratio.

SECOND GEAR In **second gear**, the shift linkage slides the 1–2 synchronizer sleeve forward, away from the first speed gear and toward the second speed gear. ● **SEE FIGURE 122–25**. The synchronizer assembly releases first gear, then locks the second speed gear to the output shaft.

With the clutch engaged, the input shaft is driven at crankshaft speed and turns the countershaft. Engine torque transfers from the second counter gear to the second speed gear, which drives the output shaft through the 1–2 synchronizer hub splines. Torque flows through the transmission in gear reduction at the second gear ratio.

THIRD GEAR In **third gear**, the shift linkage centers the 1–2 synchronizer sleeve and moves the 3–4 synchronizer sleeve back toward the third speed gear. ● **SEE FIGURE 122–26**. The synchronizer assembly locks the third speed gear to the output shaft.

With the clutch engaged and the input shaft driving the countershaft, the third counter gear transfers torque to the third speed gear. The speed gear drives the output shaft through the 3–4 synchronizer hub splines. Torque flows through the transmission in gear reduction at the third gear ratio.

FOURTH GEAR In **fourth gear**, the shift linkage moves the 3–4 synchronizer sleeve forward, away from the third speed gear and toward the input shaft drive gear. ● **SEE FIGURE 122–27**. The synchronizer assembly locks the input shaft drive gear to the output shaft.

With the clutch engaged, the input shaft drives the output shaft through the 3–4 synchronizer hub splines and both shafts rotate at crankshaft speed. Torque flows straight through the transmission

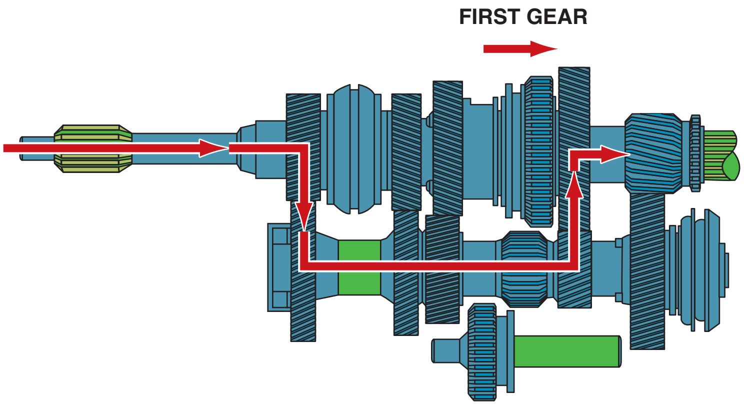

FIGURE 122–24 In first gear, the 1–2 synchronizer sleeve is moved rearward, locking the first speed gear to the output shaft. Torque is transmitted from the input shaft to the countershaft and then to the output shaft.

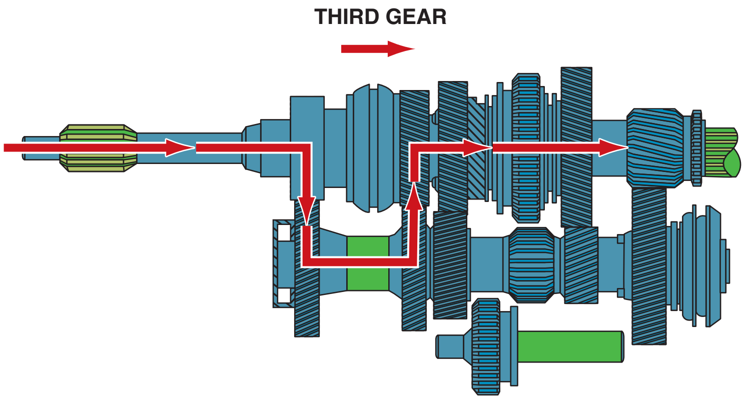

FIGURE 122–26 To achieve third gear, the shaft linkage first centers the 1–2 synchronizer sleeve and then moves the 3–4 synchronizer sleeve rearward, locking third speed gear to the output shaft.

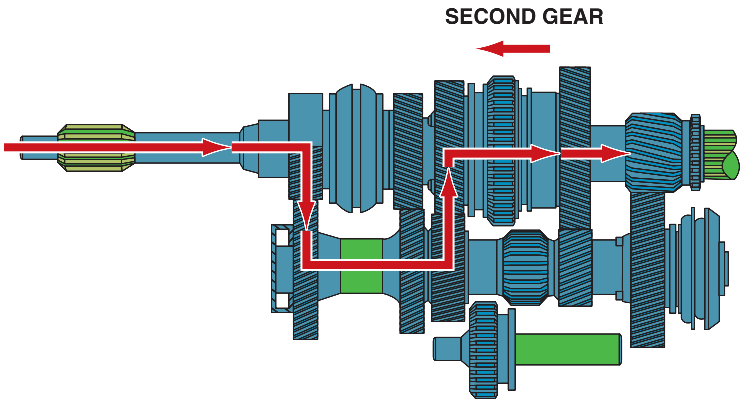

FIGURE 122–25 In second gear, the 1–2 synchronizer sleeve is moved forward, which locks the second speed gear to the output shaft.

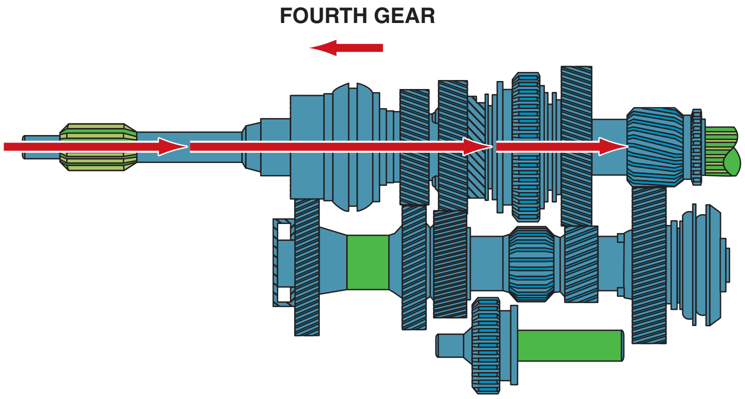

FIGURE 122–27 In fourth gear, the 3–4 synchronizer sleeve is moved forward, which locks the fourth speed gear to the output shaft.

at a 1:1 ratio, delivering engine torque to the drive shaft. This is called direct drive because there is no gear reduction through the transmission. The counter gears also turn because they are in constant mesh, but they do not affect torque flow because all of the speed gears are freewheeling on the output shaft.

FIFTH GEAR In **fifth gear**, the shift linkage centers the 3–4 synchronizer sleeve and moves the fifth synchronizer sleeve toward the fifth speed gear. ● **SEE FIGURE 122–28**. Note that on the T5 transmission the synchronizer assembly locks the fifth speed gear to the countershaft. The speed gear drives a fixed gear on the output shaft.

With the clutch engaged, the input shaft drives the countershaft. The fifth synchronizer hub is splined to the countershaft, so it is driven and driving the fifth speed gear when fifth gear is engaged. This transfers engine torque to the output shaft through the fixed fifth gear. Note the countershaft gear is larger than the output shaft gear. Therefore, fifth gear is overdriven. Torque flows through the transmission at the fifth gear, or overdrive, ratio. Typical overdrive gear ratios are between 0.6:1 and 0.8:1. This lowers engine speed for economical highway cruising.

On some five-speed transmissions, the fifth speed gear is on the output shaft with the other speed gears. This type of arrangement is typically used with constant-mesh reverse gears. In these designs, fifth and reverse gears share a synchronizer assembly. The fixed countershaft gear drives the speed gear, which drives the output shaft through the hub splines when the sliding sleeve is engaged. Torque flow through the transmission is similar to any of the gear reduction forward speeds detailed above, but the fifth speed gear is generally overdriven.

REVERSE There are two common **reverse** gear designs used on transmissions:

1. Sliding gear.
2. Constant-mesh gear.

With a **sliding reverse gear** design, such as on the Borg-Warner T5, the shift linkage slides the reverse idler gear on its shaft until it engages the reverse gears on the countershaft and output shaft gear. Both gears are fixed to their respective shafts. This design uses spur gears for reverse, not helical gears, because the gear teeth must move into and out of mesh. On some gearboxes, the sliding gear splines to the output shaft. The linkage moves the gear along the output shaft splines to engage the reverse idler gear.

An unusual feature of the Borg-Warner T5 is that it does not have a separate reverse output shaft gear. ● **SEE FIGURE 122–29**. Instead, spur teeth machined around the outside of the 1–2 synchronizer sleeve act as the reverse output gear. When the T5 is shifted into reverse, the linkage moves the reverse idler gear rearward so it simultaneously meshes with the countershaft reverse gear and the gear on the synchronizer sleeve.

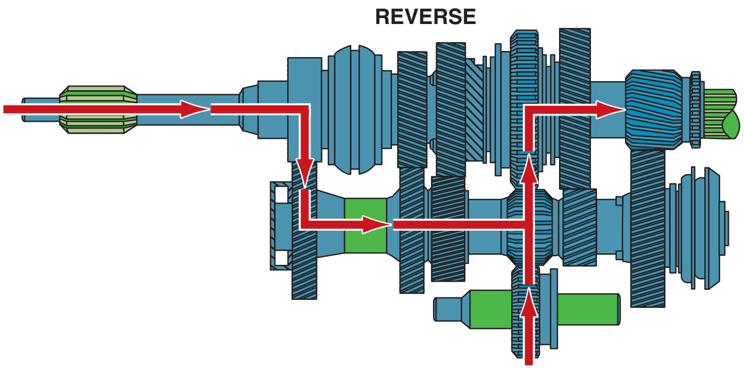

FIGURE 122–29 Torque flows through the transmission in reverse gear. Note that the idler gear drives the 1–2 synchronizer sleeve gear, which is splined to the output shaft.

When the clutch is engaged, the countershaft is driven and the reverse gear drives the idler gear, which rotates in the opposite direction of the countershaft. The idler gear drives the 1–2 synchronizer sleeve, so there is another directional change in rotation. Although the sleeve is not engaged to a speed gear, it remains splined to the output shaft, so the sleeve drives the output shaft when the idler gear is engaged. The output shaft rotates in the opposite direction of the input shaft because the idler gear is between them.

With **constant-mesh gears**, the shift linkage moves the 5-reverse synchronizer sleeve away from the fifth speed gear and toward the reverse speed gear when reverse is selected. Typically, no stop ring is used between the synchronizer sleeve and the reverse gear, so the output shaft must be stopped to engage reverse without grinding the sleeve splines against the coupling teeth of the reverse gear. The synchronizer assembly locks the reverse speed gear to the output shaft.

With the clutch engaged, the input shaft drives the countershaft. The reverse counter gear drives the reverse idler gear, which drives the reverse speed gear in the direction opposite normal rotation. The reverse speed gear drives the output shaft through the 5-reverse synchronizer hub splines. Torque flows through the transmission in gear reduction at the reverse gear ratio. The output shaft turns opposite its normal direction of rotation, so the vehicle moves to the rear. ● **SEE FIGURE 122–30**.

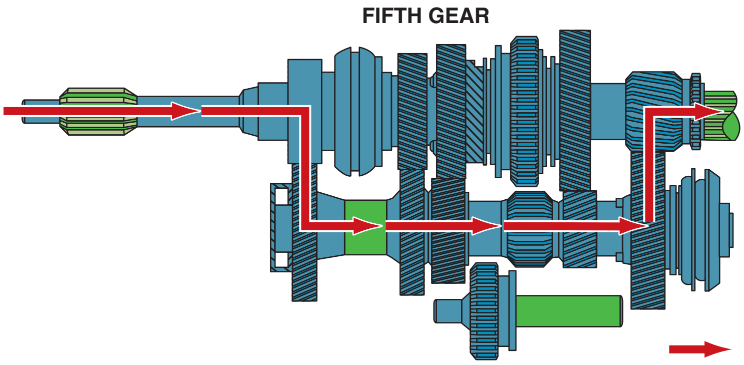

FIGURE 122–28 To achieve fifth gear, the shift linkage first centers the 3–4 synchronizer sleeve and then moves the fifth synchronizer sleeve toward the fifth speed gear, locking it to the output shaft.

MANUAL TRANSMISSION/ TRANSAXLE CONSTRUCTION AND SERVICE

MANUAL TRANSAXLE CONSTRUCTION A manually shifted transaxle includes an input shaft, an output shaft, and a differential assembly all in one case. The input shaft is attached to the clutch, which transfers engine torque from the engine flywheel to the input shaft when the clutch is engaged. Most transaxles use speed gears and synchronizers on both the input and output shafts, as shown in ● **SEE FIGURE 122–31**. The differential assembly, also called a **final drive assembly**, attaches to the output shaft and splits the torque to both front drive axles. ● **SEE FIGURE 122–32**.

HARD-TO-SHIFT DIAGNOSIS Several items that could be worn or defective can cause a manual transmission/transaxle to be difficult to shift, including

- Clutch not fully disengaging. If the clutch linkage is not properly adjusted or if there is a leak in the hydraulic clutch linkage, the clutch may not be fully disengaged. A shift is very difficult, if not impossible, if engine torque is being transferred through the transmission/transaxle as a shift is being attempted.
- Worn synchronizer. If the synchronizer rings are worn, the rings will be unable to properly match the speed gear speed, making the shift difficult and/or creating gear clash (noise) when shifting.
- Worn, cracked, or loose shift forks. If there is any problem with the shift forks, the synchronizer cannot be properly moved during a shift attempt, making shifting difficult, if not impossible. If only one fork is worn or defective, usually engaging two gears instead of one is likely.
- Excessive input- or main-shaft end play. Excessive end play in the input or main shaft will cause the gears to move away from the synchronizer assembly, resulting in grinding during shifts or shifts that are difficult or impossible to complete.
- Improper lubrication. Many of today's manual transmissions use synchronizer rings (blocking rings) that are lined with compounds, paper, or other friction material. All of these transmissions/transaxles must be filled with the proper fluid formulated for proper shifting.

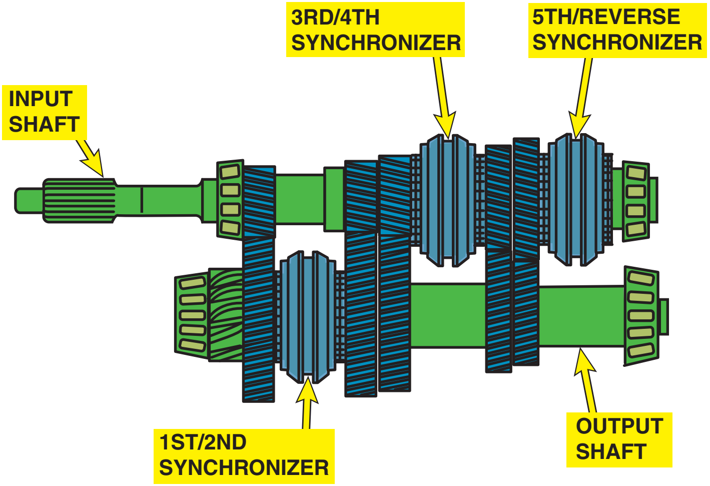

FIGURE 122–31 Notice that this five-speed transaxle from a Dodge/Plymouth Neon uses synchronizers on both the input and output shafts.

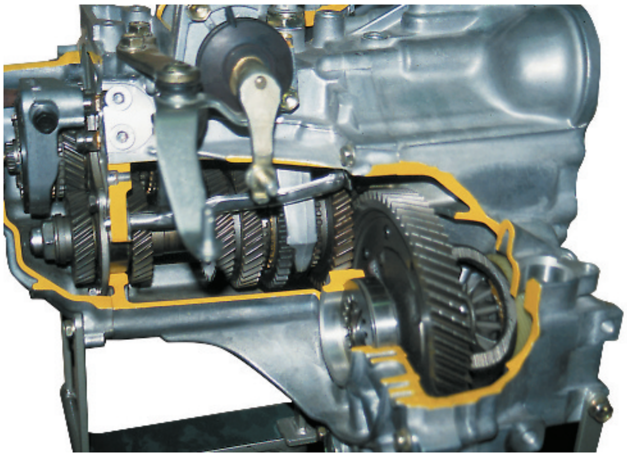

FIGURE 122–32 Cutaway of a typical manual transaxle showing all of its internal parts including the final drive assembly.

NOTE: A worn synchronizer sleeve and/or blocking ring can cause the transmission/transaxle to pop out of gear while accelerating or decelerating.

TRANSMISSION/TRANSAXLE REMOVAL Before removing the transmission/transaxle for service, double-check that the problem is not due to any malfunction of the clutch or shift linkage. To remove a transmission or transaxle, always follow the procedure in the service manual to be assured of doing no harm to either the vehicle or to yourself. Steps typically involved in the removal and disassembly include

- Disconnecting the negative battery cable.
- Safely hoisting and supporting the vehicle.
- Supporting the engine with a holding fixture or other support (front-wheel-drive). ● **SEE FIGURES 122–33 AND 122–34**.
- Removing the drive axle shafts or drive shaft (rear-wheel-drive).
- Removing the clutch linkage and shift linkage. ● **SEE FIGURE 122–35**.

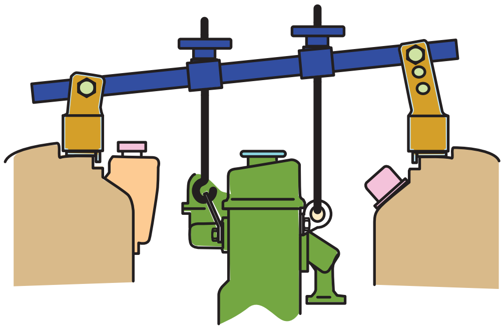

FIGURE 122–33 Most front-wheel-drive (FWD) vehicles require the use of a fixture to support the engine before removing the transaxle.

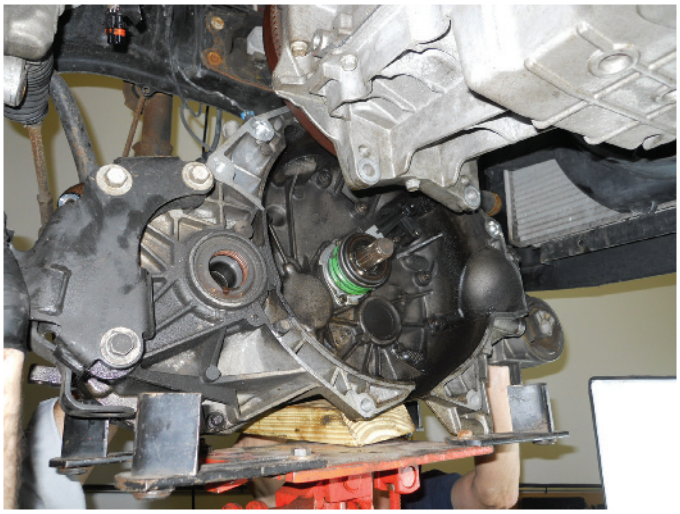

FIGURE 122–34 A transaxle being removed from underneath a vehicle and being supported by a transmission jack.

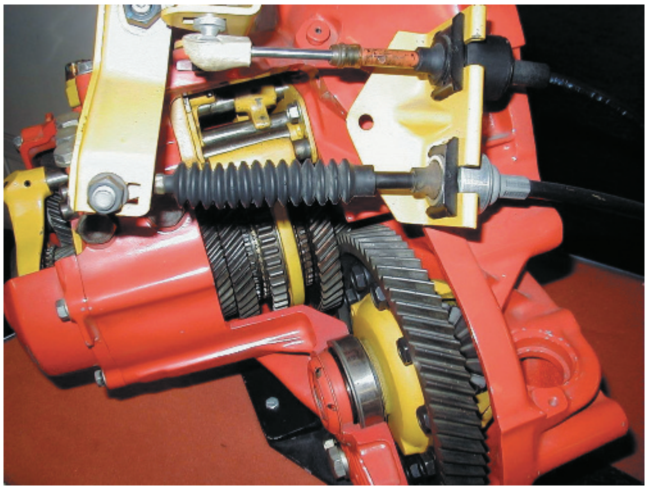

FIGURE 122–35 Typical cable-operated shift linkage used on a front-wheel-drive transaxle.

- Disconnecting the vehicle speed sensor and reverse (backup) light connectors.
- Removing the attaching bolts/nuts from the engine and transmission/transaxle mounts and then removing the unit from the vehicle.

Sometimes it is easier to remove the entire power train (engine and transaxle as an assembly) from the vehicle. When the entire assembly has been removed from the vehicle, often the transaxle can then be removed from the engine.

TRANSMISSION/TRANSAXLE DISASSEMBLY Before disassembling the transmission/transaxle, drain any remaining gear lubricant from the unit and dispose of it properly. ● **SEE FIGURE 122–36**.

CAUTION: Most extreme pressure (EP) lubricants contain sulfur compounds that can cause skin irritation. Either wear protective gloves or wash your hands thoroughly using soap and water after exposure to used gear lubricant.

Mount the transmission/transaxle on a holding fixture or place it on a large, clean work surface. Many vehicle manufacturers recommend removing the shift housing before further disassembly. The removal of the shifter housing allows the technician to see any obvious damage as well as providing the opportunity to check the shift forks, which are frequently worn in manually shifted transmissions/transaxles. ● **SEE FIGURES 122–37 AND 122–38**.

TECH TIP

Manual Transmission Service Tips

A wise technician once told a beginning technician to remember these items when working with transmissions:

- Always use a *brass* or *plastic* hammer when pounding on a steel or aluminum component.
- If using a steel hammer, always use a *brass* or *aluminum* punch or place wood between the steel components and the hammer.
- Many parts can be installed in either direction but usually only one way is correct.
- If you are exerting a lot of force, you are probably doing something wrong.
- Many drive train parts are pulled or pressed off and pressed or driven on.

The disassembly and reassembly of a manual transaxle is similar to that for a manual transmission except for the addition of the final drive unit. Some transaxles require two people for disassembly and reassembly because often the shift linkage has to be held in place while assembled components are placed into the case, as shown in ● **FIGURE 122–39**.

Check the service manual for the exact disassembly procedures to follow for the unit being serviced. Sometimes the main shaft is removed through the rear of the transmission and sometimes it is removed through the top of the case. Also look for hidden snap rings. ● **SEE FIGURES 122–40 AND 122–41**. Also see the Tech Tip titled “Manual Transmission Service Tips.”

END PLAY/PRELOAD CHECKS During the reassembly of a transaxle/transmission that uses tapered roller bearings, the preload or end play of each shaft should be checked. A selective shim is located at a bearing at one end of each shaft, and the thickness of this shim controls the amount of preload or end play.

- Preload causes a slight drag as a shaft is rotated, and it is usually measured using a torque wrench or spring scale.
- End play is a free, lengthwise movement of the shaft and is usually measured using a dial indicator or feeler gauge. ● **SEE FIGURE 122–42**.

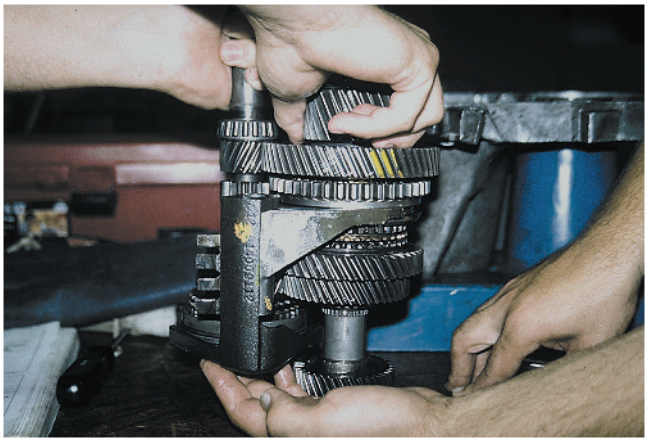

FIGURE 122–39 It often requires two people to assemble a transaxle because the shaft with the shifter forks needs to be placed into the case as an assembly, as on this unit.

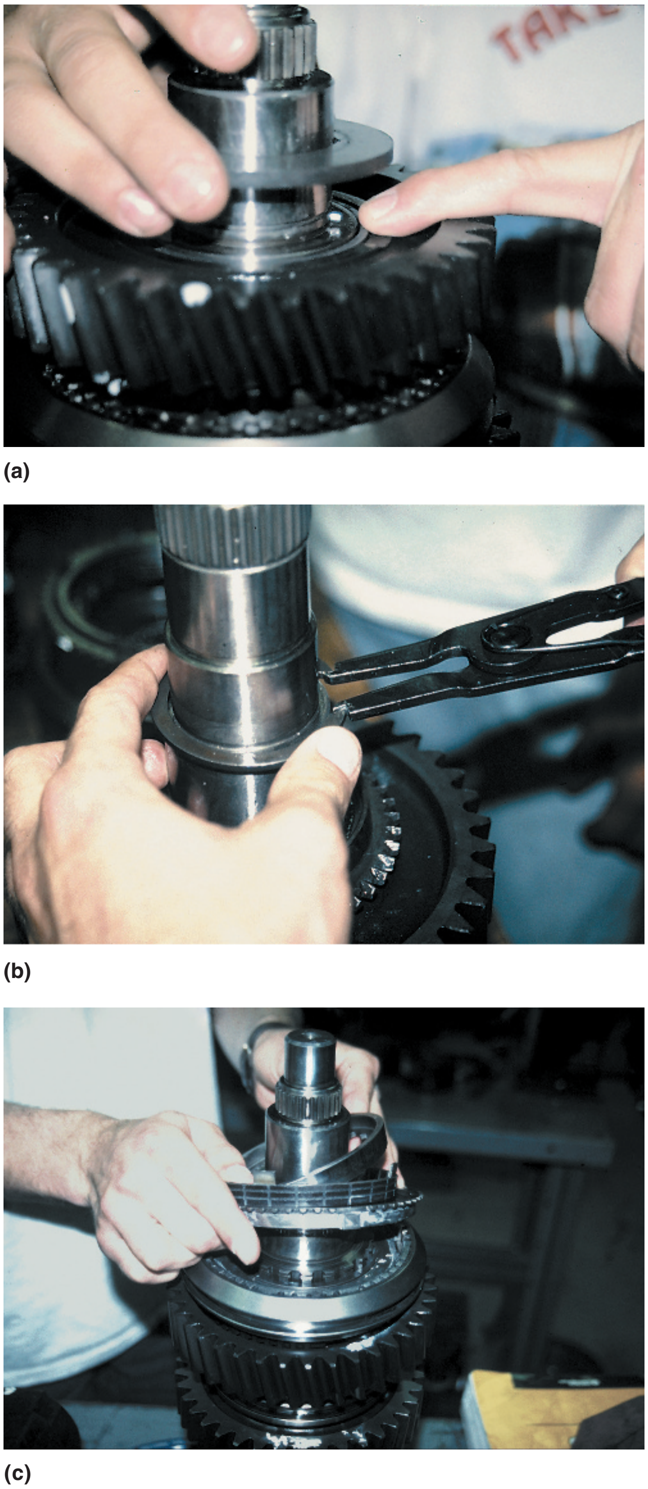

FIGURE 122–40 (a) During the disassembly of any manual transmission/transaxle, carefully check for the location of the snap rings. Often they are hidden. Consult the factory service manual or unit repair manual for information and procedures for the unit being serviced. (b) Using snap-ring pliers to remove a snap ring. Many snap rings have an “up” side. Be sure to reinstall any snap rings in the correct direction. (c) After the snap ring is removed, some components can be simply lifted off the main shaft, while other gears may require the use of a press.

MANUAL TRANSMISSION INSTALLATION When installing a repaired or replacement transmission/transaxle, the clutch should be carefully inspected and replaced as necessary. The clutch friction disc must be held in position using an alignment tool that is secured in the pilot bearing. This holds the disc in

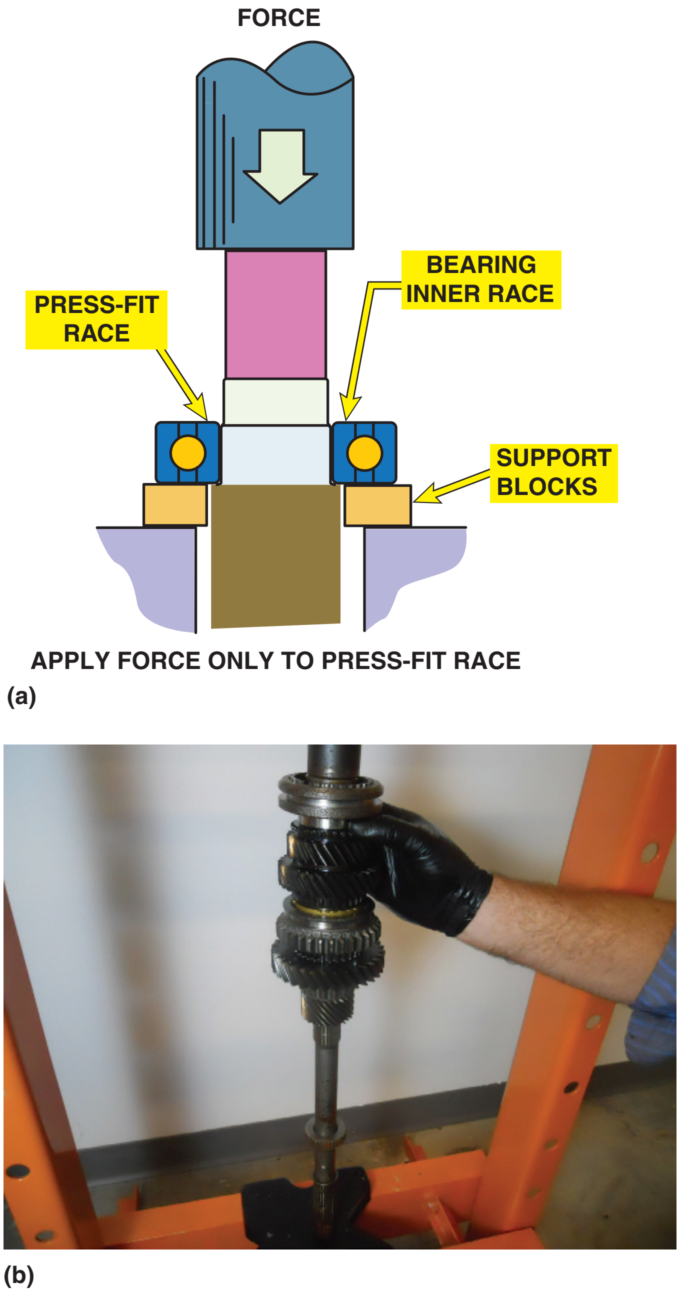

FIGURE 122–41 (a) When a ball bearing is pressed off a shaft, the bearing should be supported by the inner race (if possible) so the force is not exerted on the outer race by the balls. position while the pressure plate is being installed. Finally, the engine bell housing is put on the engine, if it was not installed before. The alignment of this type of bell housing is then checked.

CAUTION: Perfectly round cylinders can be distorted whenever another part of the engine is bolted and torqued to the engine block. For example, it has been determined that after the cylinders are machined, the rear cylinder bore can be distorted as much as 0.006 inch (0.15 millimeter) out-of-round after the bell housing is bolted onto the block! To help prevent this distortion, always apply the specified torque to all fasteners going into the engine block and tighten in the recommended sequence.

CASE STUDY

The Worn Shift Fork Mystery

A vehicle equipped with a manual transmission had to be repaired several times for worn shift forks. Even though the vehicle warranty paid for the repair, both the customer and the service department personnel were concerned about the repeated failures. All technical service bulletins (TSBs) were checked to see if there was an updated, improved shift fork. No luck. Even the manufacturer's technical assistance personnel were unable to determine why the shift forks were wearing out. After the third repair, the service technician rode with the customer to see if the cause could be determined. As the driver got into the driver's seat, she placed the handle of her purse over the shifter on the floor and allowed the purse to hang from the shifter. The technician asked the owner if she always placed her purse on the shifter and when she said yes, the technician knew immediately the cause of the worn shift forks. The purse exerted a force on the shifter all the time. This force pushed the shift forks against the synchronizer sleeve. Because the sleeve rotates all the time the vehicle is in motion, the shift forks were quickly worn. The service technician should have determined the root cause of the problem after the *first* repair. The customer agreed to find another location for her purse so that the transmission problem would not reoccur.

Summary:

Complaint—Driver complained of repeated transmission failures.
Cause—The root cause was found to be that the driver was hanging their purse over the floor shifter causing wear to occur to the shift forks.
Correction—The driver found another location for her purse.

The clutch release yoke should be checked for free movement. Usually, the clutch release bearing is replaced, ensuring that the new bearing is securely attached to the clutch release yoke. The transmission can then be installed.

The transmission clutch shaft must be guided straight into the clutch disc and pilot bearing. The transmission clutch shaft is rotated, as required, to engage in the splines of the clutch disc. The assembly bolts are secured when the transmission fully mates with the bell housing.

CAUTION: Always adjust the clutch free play *before* starting the engine to help prevent thrust bearing damage.

Complete the installation by attaching the transmission/transaxle mount, driveshaft (drive axle shafts), vehicle speed sensor, and reverse (backup) light switch.

GEAR LUBRICATION

After the installation of the transmission/transaxle, the unit should be filled with the correct lubricant. The various lubricants, their general use, and their American Petroleum Institute (API) rating include

GL-1 Straight mineral oil
GL-2 Worm-type gear lubricant
GL-3 Mild-type EP lubricant (will not protect hypoid gears)
GL-4 EP-type lubricant (okay for manual transmissions/transaxles)
GL-5 EP-type okay for hypoid gears and for Mil-L2150B (military)

DRIVESHAFTS AND HALF SHAFTS

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Describe driveshaft design.
- Describe driveshaft balance.
- Describe the function and operation of U-joints.
- Discuss double-Cardan joints.
- Discuss the two types of CV joints and how they work.

KEY TERMS:

DRIVESHAFTS

PURPOSE AND FUNCTION A driveshaft transmits engine torque from the transmission or transaxle (if front-wheel drive) to the rear axle assembly or drive wheels. ● **SEE FIGURES 123–1 AND 123–2**.

Driveshaft is the term used by the Society of Automotive Engineers (SAE) to describe the shaft between the transmission and the rear axle assembly on a rear-wheel-drive vehicle. General Motors and some other manufacturers use the term **propeller shaft** or *prop shaft* to describe this same part. The SAE term will be used throughout this textbook.

A typical driveshaft is a hollow steel tube. A splined end yoke is welded onto one end that slips over the splines of the output shaft of the transmission. ● **SEE FIGURE 123–3**. An end yoke is welded onto the other end of the driveshaft. Some driveshafts use a center support bearing.

DRIVESHAFT DESIGN Most driveshafts are constructed of hollow steel tubing. *The forces are transmitted through the surface of the driveshaft tubing.* The surface is therefore in tension, and cracks can develop on the outside surface of the driveshaft due to metal fatigue. Driveshaft tubing can bend and, if dented, collapse. A dented driveshaft should be replaced and no attempt should be made to repair the dent. ● **SEE FIGURE 123–4**.

Most rear-wheel-drive cars and light trucks use a one- or two-piece driveshaft. A steel tube driveshaft has a maximum *length of about 65 inches (165 cm)*. Beyond this critical length, a **center support bearing** must be used, as shown in ● **FIGURE 123–5**. A center support bearing is also called a steady bearing or hanger bearing.

Some vehicle manufacturers use aluminum driveshafts; these can be as long as 90 inches (230 cm) with no problem. Many extended-cab pickup trucks and certain vans use aluminum driveshafts to eliminate the need (and expense) of a center support bearing. Composite-material driveshafts are also used in some vehicles. These carbon-fiber-plastic driveshafts are very strong yet lightweight and can be made in extended lengths without the need for a center support bearing.

To dampen driveshaft noise, it is common to line the inside of the hollow driveshaft with cardboard or rubber. This helps eliminate the tinny sound whenever shifting between drive and reverse in a vehicle equipped with an automatic transmission. ● **SEE FIGURE 123–6**.

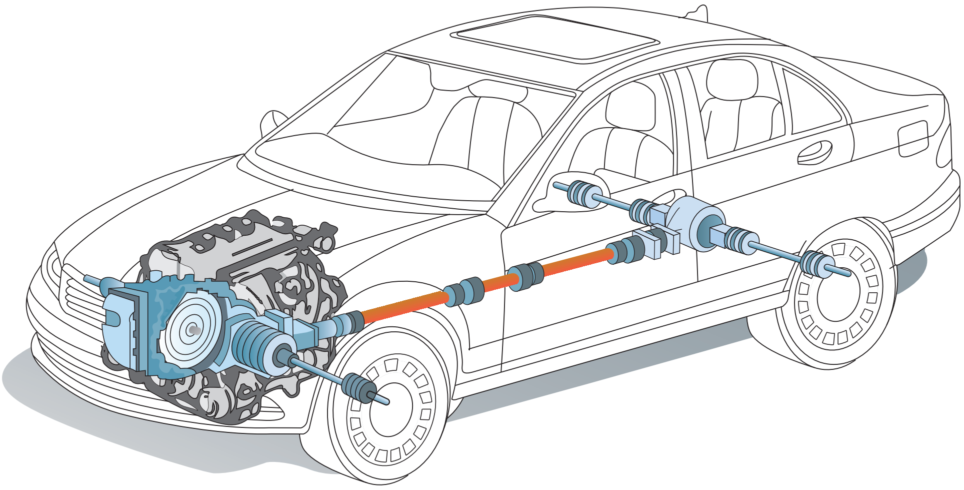

FIGURE 123–1 A vehicle equipped with all-wheel drive using a transaxle uses many different driveshafts. From the transaxle to the front wheels, two "half shafts" are used. In this example, the multi-piece driveshaft is used to transmit engine torque to the drive axle at the rear of the vehicle. From the drive axle, two more half-shafts (drive axle shafts) are used to transmit torque to the rear wheels.

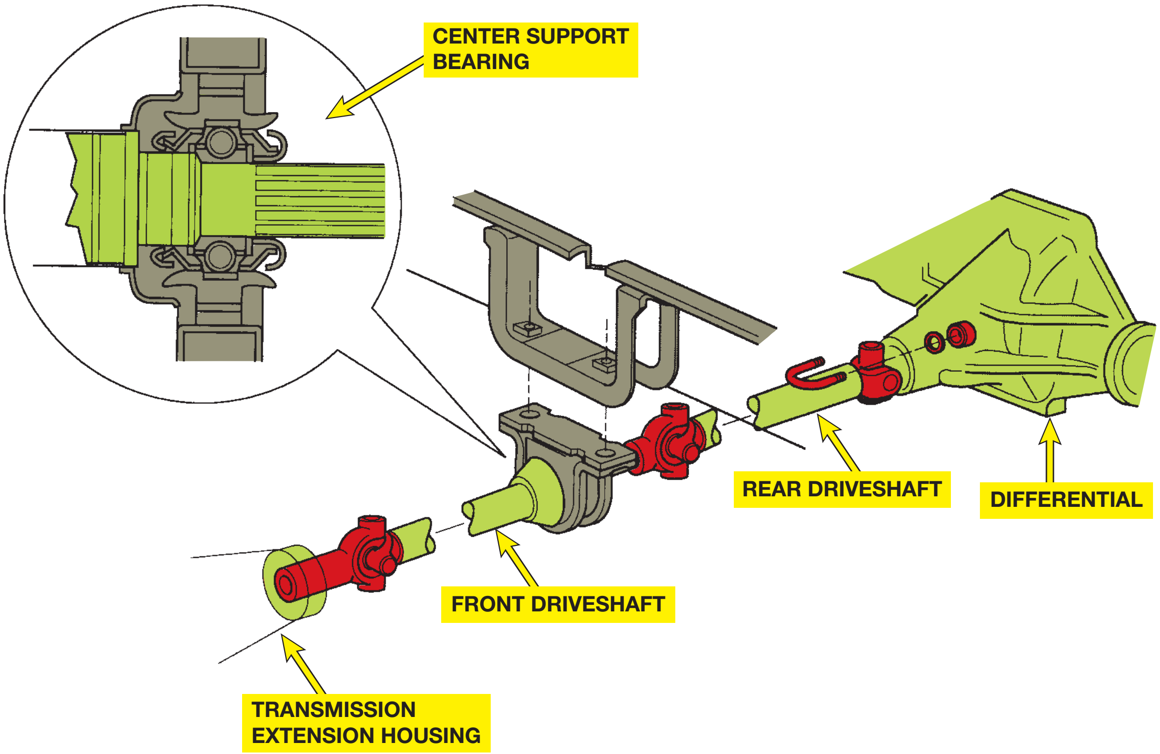

FIGURE 123–5 A center support bearing is used on many vehicles with long two-part driveshafts.

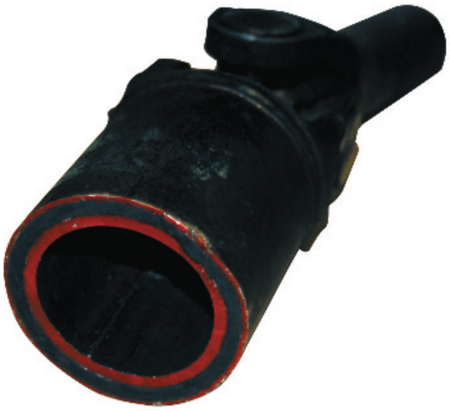

FIGURE 123–6 Some driveshafts use rubber between an inner and outer housing to absorb vibrations and shocks to the driveline.

DRIVESHAFT BALANCE

All driveshafts are balanced. Generally, any driveshaft whose rotational speed is greater than 1000 RPM must be balanced. Driveshaft balance should be within 0.5% of the driveshaft weight. One of the reasons why aluminum or composite driveshafts can be longer is because of their light weight.

Driveshafts are often not available by make, model, and year of the vehicle. There are too many variations at the factory, such as transmission type, differential, or U-joint type. To get a replacement driveshaft, it is usually necessary to know the series of U-joints (type or style of U-joint) and the center-to-center distance between the U-joints.

U-JOINT DESIGN AND OPERATION

Universal joints (U-joints) are used at both ends of a driveshaft. U-joints allow the wheels and the rear axle to move up and down, remain flexible, and still transfer torque to the drive wheels. A simple universal joint can be made from two Y-shaped yokes connected by a crossmember called a cross or **spider**. The four arms of the cross are called **trunnions**. ● **SEE FIGURE 123–7** for a line drawing of a simple U-joint with all part names identified. A similar design is the common U-joint used with a socket wrench set.

Most U-joints are called cross-yoke joints or **Cardan joints**. *Cardan* is named for a sixteenth-century Italian mathematician who worked with objects that moved freely in any direction. Torque from the engine is transferred through the U-joint. The engine drives the

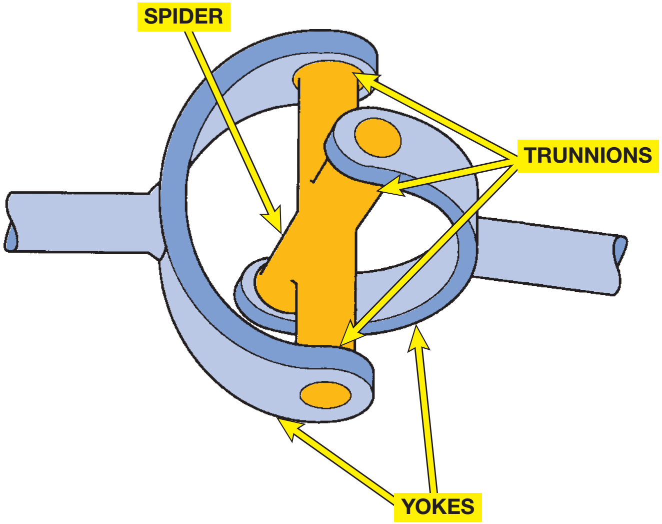

FIGURE 123–7 A simple universal joint (U-joint).

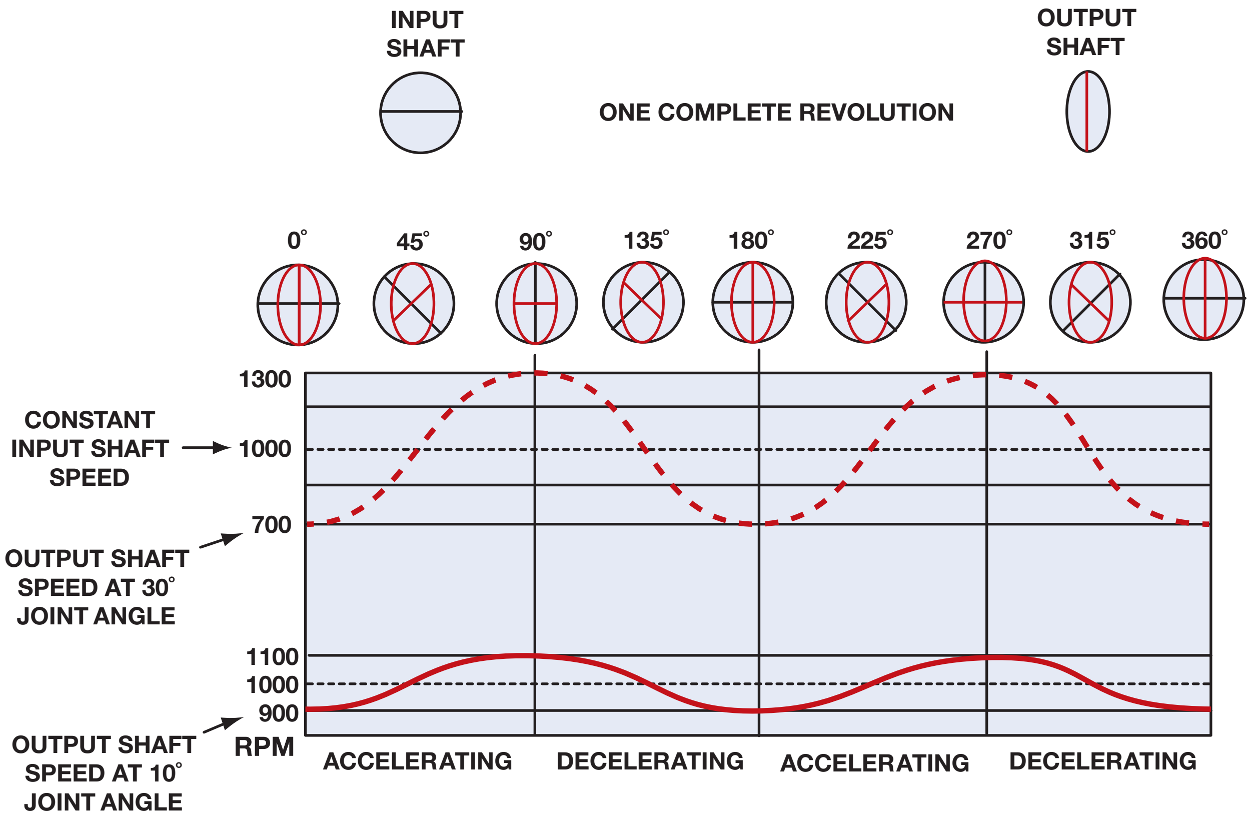

FIGURE 123–8 How the speed difference on the output of a typical U-joint varies with the speed and the angle of the U-joint. At the bottom of the chart, the input speed is a constant 1000 RPM, while the output speed varies from 900 to 1100 RPM when the angle difference in the joint is only 10 degrees. At the top of the chart, the input speed is a constant 1000 RPM, yet the output speed varies from 700 to 1200 RPM when the angle difference in the joint is changed to 30 degrees.

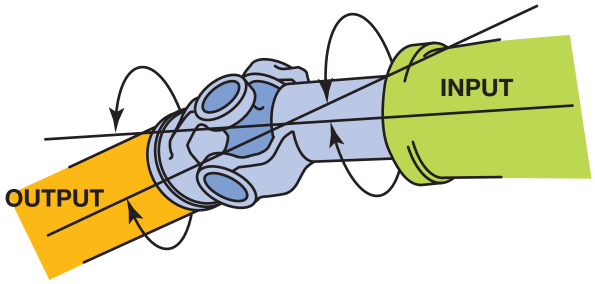

FIGURE 123–9 The joint angle is the difference between the angles of the joint.

U-joint at a constant speed, but the output speed of the U-joint changes because of the angle of the joint. The speed changes twice per revolution. *The greater the angle, the greater the change in speed (velocity)*. ● **SEE FIGURE 123–8**.

If only one U-joint were used in a driveline, this change in speed of the driven side (output end) would generate vibrations in the driveline. To help reduce vibration, another U-joint is used at the other end of the driveshaft. If the angles of both joints are nearly equal, the acceleration and deceleration of one joint is offset by the alternate deceleration and acceleration of the second joint. *It is very important that both U-joints operate at about the same angle to prevent excessive driveline vibration*. ● **SEE FIGURE 123–9**.

ACCEPTABLE WORKING ANGLES Universal joints used in a typical driveshaft should have a *working angle* of 1/2 to 3 degrees. ● **SEE FIGURE 123–10**. The working angle is the angle between the driving end and the driven end of the joint.

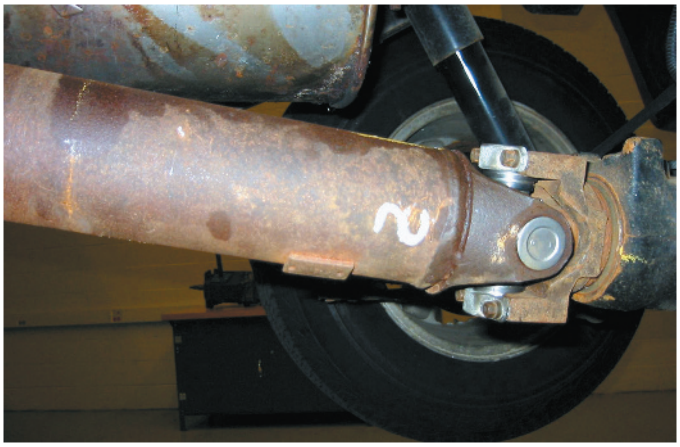

FIGURE 123–10 The angle of this rear-Cardan U-joint is noticeable.

If the driveshaft is perfectly straight (0 degree working angle), then the needle bearings inside the bearing cap are not revolving because there is no force (no difference in angles) to cause the rotation of the needle bearings. If the needle bearings do not rotate, they can exert a constant pressure in one place and damage the bearing journal. If a two-piece driveshaft is used, one U-joint (usually the front) runs at a small working angle of about 1/2 degree, just enough to keep the needle bearings rotating. The other two U-joints (from the center support bearing and rear U-joint at the differential) operate at typical working angles of a single-piece driveshaft.

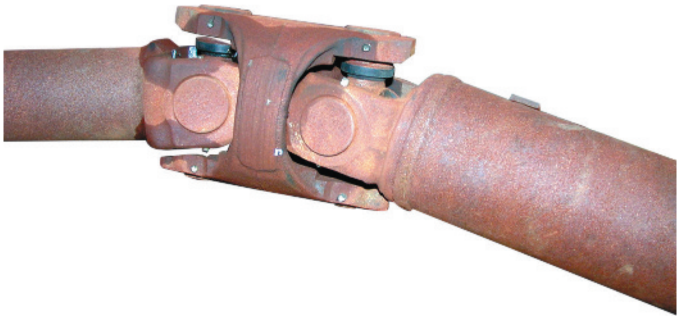

FIGURE 123–11 A double-Cardan U-joint.

If the U-joint working angles differ by more than a 1/2 degree between the front and the rear joint, a vibration is usually produced that is *torque sensitive.* As the vehicle is first accelerated from a stop, engine torque can create unequal driveshaft angles by causing the differential to rotate on its suspension support arms. This vibration is most noticeable when the vehicle is heavily loaded and being accelerated at lower speeds. The vibration usually diminishes at higher speeds due to decrease in the torque being transmitted. If the driveshaft angles are excessive (over 3 degrees), a vibration is usually produced that increases as the speed of the vehicle (and driveshaft) increases.

DOUBLE-CARDAN JOINTS

Regular U-joints are usually designed to work up to 12 degrees of angularity. If two Cardan-style U-joints are joined together, the angle at which this **double-Cardan joint** can function is about 18 to 20 degrees. ● **SEE FIGURE 123–11**.

Double-Cardan U-joints were first used on large rear-wheel-drive vehicles to help reduce drive line-induced vibrations, especially when the rear of the vehicle was fully loaded and driveshaft angles were at their greatest. As long as a U-joint (either single or double Cardan) operates in a straight line, the driven shaft will rotate at the same constant speed (velocity) as the driving shaft. As the angle increases, the driven shaft speed or velocity varies during each revolution. This produces pulsations and a noticeable vibration or surge.

NOTE: Many four-wheel-drive light trucks use standard Cardan-style U-joints in the front drive axles. If the front wheels are turned sharply and then accelerated, the entire truck often shakes due to the pulsations created by the speed variations through the U-joints. This vibration is normal and cannot be corrected. It is characteristic of this type of design and is usually not noticeable in normal driving.

CONSTANT VELOCITY JOINTS

PURPOSE AND FUNCTION Constant velocity joints, commonly called CV joints, are designed to rotate without changing speed.

RZEPPA JOINTS The first constant velocity joint was designed by Alfred H. Rzeppa (pronounced shep'pa) in the mid-1920s. The **Rzeppa joint** transfers torque through six round balls that are held in position midway between the two shafts. This design causes the angle between the shafts to be equally split regardless of the angle. ● **SEE FIGURE 123–12**. Because the angle is always split equally, torque is transferred equally without the change in speed (velocity) that occurs in Cardan-style U-joints. This style of joint results in a constant velocity between driving and driven shafts. It can also function at angles greater than simple U-joints can, up to 40 degrees.

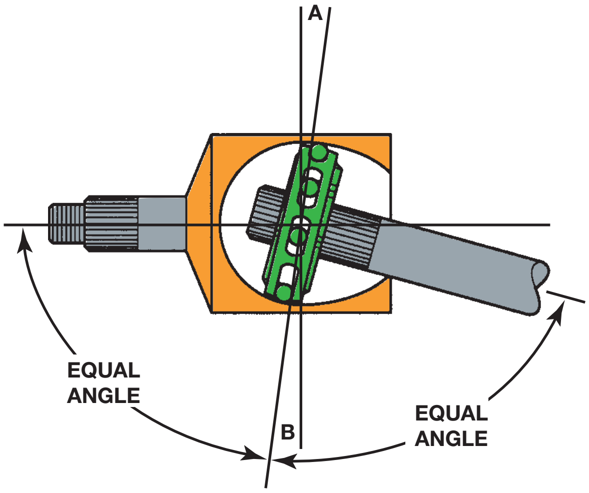

FIGURE 123–12 A constant velocity (CV) joint can operate at high angles without a change in velocity (speed) because the joint design results in equal angles between input and output.

NOTE: CV joints are also called LOBRÖ joints, the brand name of an original equipment manufacturer.

While commonly used today in all front-wheel-drive vehicles and many four-wheel-drive vehicles, its first use was on the

FREQUENTLY ASKED QUESTION

What Is a 1350-Series U-Joint?

Most universal joints are available in sizes to best match the torque that they transmit. The larger the U-joint, the higher the amount of torque. Most U-joints are sized and rated by series numbers. See the accompanying chart for series numbers and sizes.

Series Number	Cap Diameter (in.)	Overall Length (in.)	Trunnion Diameter (in.)

front-wheel-drive 1929 Cord. Built in Auburn, Indiana, the Cord was the first front-wheel-drive car to use a CV-type drive axle joint.

OUTER CV JOINTS The Rzeppa-type CV joint is most commonly used as an outer joint on most front-wheel-drive vehicles. ● **SEE FIGURE 123–13**. The outer joint must do the following:

1. Allow up to 40 degrees or more of movement to allow the front wheels to turn.
2. Allow the front wheels to move up and down through normal suspension travel in order to provide a smooth ride over rough surfaces.
3. Be able to transmit engine torque to drive the front wheels.

Outer CV joints are called **fixed joints**. The outer joints are also attached to the front wheels. They are more likely to suffer from road hazards that often can cut through the protective outer flexible boot. ● **SEE FIGURE 123–14**. Once this boot has been split open, the special high-quality grease is thrown out and contaminants such as dirt and water can enter. Some joints cannot be replaced individually if worn. ● **SEE FIGURE 123–15**.

NOTE: Research has shown that in as few as eight hours of driving time, a CV joint can be destroyed by dirt, moisture, and a lack of lubrication if the boot is torn. The technician should warn the owner as to the possible cost involved in replacing the CV joint itself whenever a torn CV boot is found.

INNER CV JOINTS Inner CV joints attach the output of the transaxle to the drive axle shaft. Inner CV joints are therefore inboard, or toward the center of the vehicle. ● **SEE FIGURE 123–16**.

Inner CV joints have to be able to perform two very important movements:

1. Allow the drive axle shaft to move up and down as the wheels travel over bumps.
2. Allow the drive axle shaft to change length as required during vehicle suspension travel movements (lengthening and

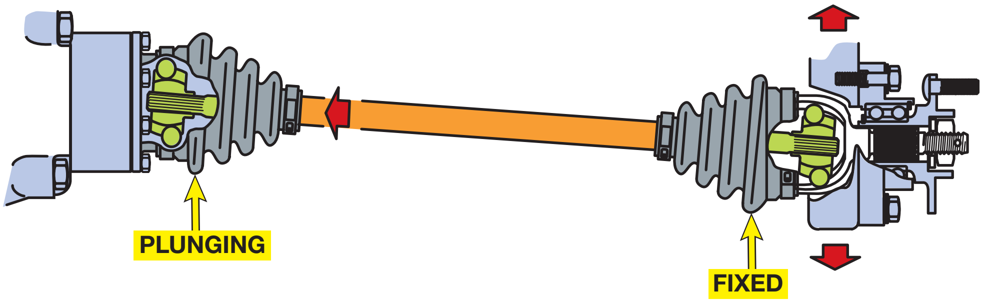

FIGURE 123–16 The fixed outer joint is required to move in all directions because the wheels must turn for steering as well as move up and down during suspension movement. The inner joint has to be able to not only move up and down but also plunge in and out as the suspension moves up and down.

shortening as the vehicle moves up and down; same as the slip yoke on a conventional RWD driveshaft). CV joints are also called **plunge joints**.

Typical types of inner CV joints that are designed to move axially, or *plunge,* include the following:

1. Tripod. ● **SEE FIGURE 123–17**.
2. Cross-groove. ● **SEE FIGURE 123–18**.
3. Double offset. ● **SEE FIGURE 123–19**.

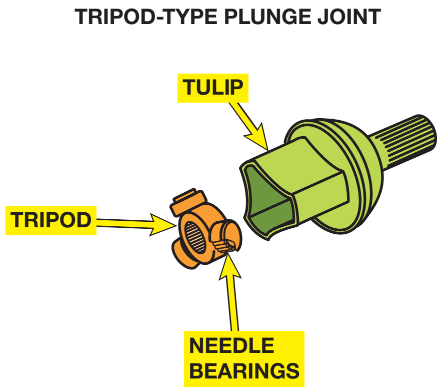

FIGURE 123–17 A tripod joint is also called a tripot, tripode, or tulip design.

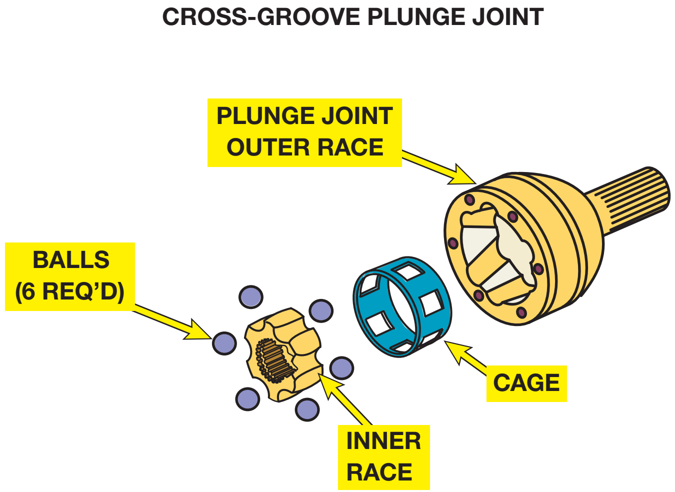

FIGURE 123–18 A cross-groove plunge joint is used on many German front-wheel-drive vehicles and as both inner and outer joints on the rear of vehicles that use an independent-type rear suspension.

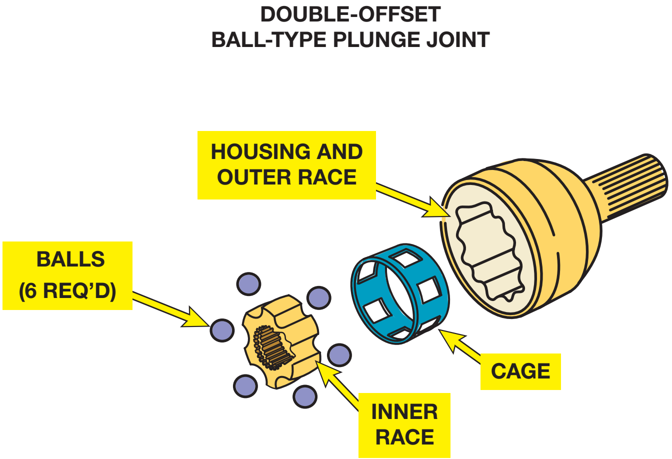

FIGURE 123–19 Double-offset ball-type plunge joint.

HALF SHAFTS Unequal-length **half shafts** result in unequal drive axle shaft angles to the front drive wheels. ● **SEE FIGURE 123–20**. This unequal angle often results in a pull on the steering wheel during acceleration. This pulling to one side during acceleration due to unequal engine torque being applied to the front drive wheels is called torque steer. To help reduce the effect of torque steer, some vehicles are manufactured with an intermediate shaft that results in equal drive axle shaft angles. Both designs use fixed outer CV joints with plunge-type inner joints.

FREQUENTLY ASKED QUESTION

What Is That Weight for on the Drive Axle Shaft?

Some drive axle shafts are equipped with what looks like a balance weight. ● **SEE FIGURE 123–21**. It is actually a dampener weight used to dampen out certain drive line vibrations. The weight is not used on all vehicles and may or may not appear on the same vehicle depending on engine, transmission, and other options. The service technician should always try to replace a defective or worn drive axle shaft with the exact replacement. When replacing an entire drive axle shaft, the technician should always follow the manufacturer's instructions regarding either transferring or not transferring the weight to the new shaft.

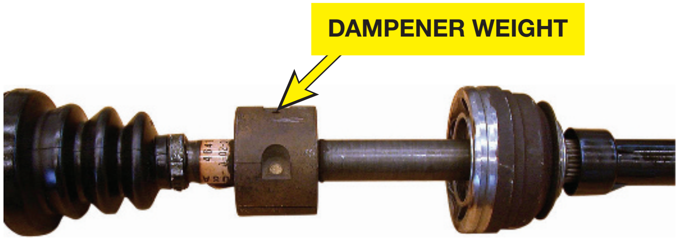
EQUAL-LENGTH HALF SHAFTS

FIGURE 123–20 Unequal-length driveshafts result in unequal drive axle shaft angles to the front drive wheels. This unequal angle side to side often results in a steering of the vehicle during acceleration called torque steer. By using an intermediate shaft, both drive axles are the same angle and the torque steer effect is reduced.



DAMPENER WEIGHT

FIGURE 123–21 A typical drive axle shaft with dampener weight.

CV JOINT BOOT MATERIALS The pliable boot surrounding the CV joint, or **CV joint boot**, must be able to remain flexible under all weather conditions and still be strong enough to avoid being punctured by road debris. There are four basic types of boot materials used over CV joints:

1. *Natural rubber* (black) uses a bridge-type stainless steel clamp to retain.
2. *Silicone rubber* (gray) is a high-temperature-resistant material that is usually used only in places that need heat protection, such as the inner CV joint of a front-wheel-drive vehicle.
3. *Hard thermoplastic* (black) is a hard plastic material requiring heavy-duty clamps and a lot of torque to tighten (about 100 lb-ft!).
4. *Urethane* (usually blue) is a type of boot material usually found in an aftermarket part. ● **SEE FIGURE 123–22**.

TONE WHEEL
STEERING KNUCKLE

FIGURE 123–22 Many outer CV joints include the tone wheel for the wheel speed sensor used by the anti-lock and stability control systems.

NOTE: Some aftermarket companies offer a split-style replacement CV joint boot. Being split means that the boot can be replaced without having to remove the drive axle shaft. Vehicle manufacturers usually do *not* recommend this type of replacement boot because the joint cannot be disassembled and properly cleaned with the drive axle still in the vehicle. The split boots must also be kept perfectly clean (a hard job to do with all the grease in the joint) in order to properly seal the seam on the split boot.

It is important that boot seals be inspected regularly and replaced if damaged. The inboard (plunging joint) can often pump water into the joint around the seals or through small holes in the boot material itself because the joint moves in and out. Seal retainers are used to provide a leakproof connection between the boot seal and the housing or axle shaft.

CV JOINT GREASE CV joints require special greases. Grease is an oil with thickening agents. Greases are named for the thickening agents used.

Most CV joint grease is molybdenum-disulfide-type grease, commonly referred to as *moly* grease. The exact composition of grease can vary depending on the CV joint manufacturer. *The grease supplied with a replacement CV joint or boot kit should be the only grease used*.

The exact mix of chemicals, viscosity (thickness), wear, and corrosion-resistant properties varies from one CV joint application to another. Some technicians mistakenly think that the *color* of the grease determines in which CV joint it is used. The color—such as black, blue, red, or tan—is used to identify the grease during manufacturing and packaging as well as to give the grease a consistent, even color (due to blending of various ingredients in the grease).

The exact grease to use depends on many factors, including the following:

1. The type (style) of CV joint. For example, outer (fixed) and inner (plunging) joints have different lubricating needs.
2. The location of the joint on the vehicle. For example, inner CV joints are usually exposed to the greatest amount of heat.
3. The type of boot. The grease has to be compatible with the boot material.

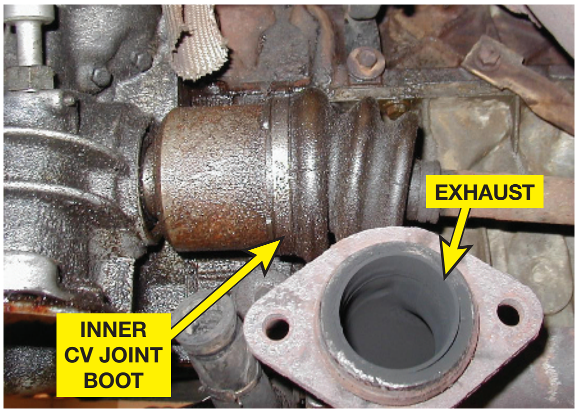

FIGURE 123–23 Many CV joints are close to the exhaust system where they are exposed to higher than normal temperatures.

TECH TIP

CV Joint Boots Are in a Hot Place

While the outer CV boots move when the front wheels are steered, the inner boots are also subjected to possible damage because they are often near the exhaust system where the high temperatures can damage the boot material. Then, if there is an engine oil leak, the engine oil could harm the CV boot too. Try to fix all leaks to help prevent premature CV boot failure. ● **SEE FIGURE 123–23**.

REVIEW QUESTIONS

DRIVESHAFT AND HALF SHAFTS SERVICE

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Explain how to diagnose a U-joint.
- Explain how to inspect a driveshaft and U-joint.
- List the steps necessary to replace a U-joint.
- Explain how to measure U-joint working angles.
- Discuss CV joint diagnosis and replacement shaft assemblies.
- Describe the service procedures for replacing CV joints.

KEY TERMS:

Inclinometer 1566 • Pin bushings 1565 • Pinch bolt 1567 • Spline bind 1570 • Synthetic retainers 1565 • Prevailing torque nut 1569 • U-joints 1563

U-JOINT DIAGNOSIS

BACKGROUND The driveshaft of a typical rear-wheel-drive (RWD) vehicle rotates about three times faster than the wheels. This is due to the gear reduction that occurs in the differential. The differential not only provides gear reduction but also allows for a difference in the speed of the rear wheels that is necessary whenever turning a corner.

The driveshaft rotates at the same speed as the engine if the transmission ratio is 1 to 1 (1:1). The engine speed, in revolutions per minute (RPM), is transmitted through the transmission at the same speed. In lower gears, the engine speed is many times faster than the output of the transmission. Most transmissions today, both manual and automatic, have an overdrive gear. This means that at highway speeds, the driveshaft is rotating faster than the engine.

SYMPTOMS OF DEFECTIVE U-JOINTS The driveshaft must travel up and down as the vehicle moves over bumps and dips in the road while rotating and transmitting engine power to the drive wheels. The driveshaft and universal joints should be carefully inspected whenever any of the following problems or symptoms occur:

1. Vibration or harshness at highway speed
2. A clicking sound whenever the vehicle is moving either forward or in reverse
3. A clunking sound whenever changing gears, such as moving from drive to reverse

DRIVESHAFT AND U-JOINT INSPECTION

The driveshaft should be inspected for the following:

1. Any dents or creases caused by incorrect hoisting of the vehicle or by road debris.

CAUTION: A dented or creased driveshaft can collapse, especially when the vehicle is under load. This collapse of the driveshaft can cause severe damage to the vehicle and may cause an accident.

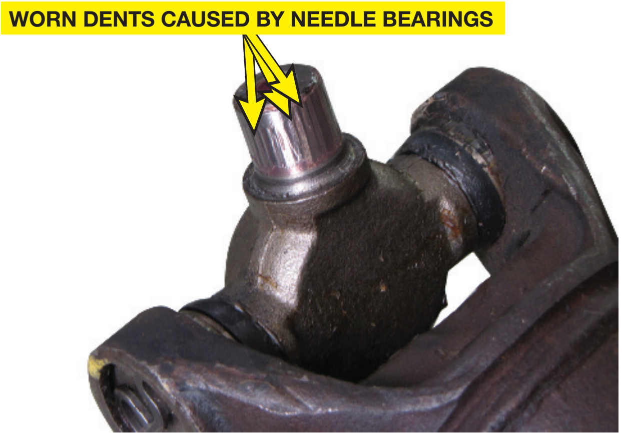

FIGURE 124–1 Notice how the needle bearings have worn grooves, called Brinelling, into the bearing surface of the U-joint.

CASE STUDY

The Squeaking Pickup Truck

The owner of a pickup truck complained that a squeaking noise occurred while driving in reverse. The "eeee eeee eeee" sound increased in frequency as the truck increased in speed, yet the noise did not occur when driving forward.

Because there was no apparent looseness in the U-joints, the service technician at first thought that the problem was inside either the transmission or the rear axle. When the driveshaft was removed to further investigate the problem, it became obvious where the noise was coming from. The U-joint needle bearing had worn the cross-shaft bearing surface of the U-joint. ● **SEE FIGURE 124–1**. The noise occurred only in reverse because the wear had occurred in the forward direction, and therefore only when the torque was applied in the opposite direction did the needle bearing become bound up and start to make noise. A replacement U-joint solved the squeaking noise in reverse.

Summary:

Complaint—Customer complained of squeaking sound but only while driving in reverse.
Cause—A worn U-joint was found to be the cause.
Correction—The worn U-joint was replaced and the noise issue was corrected.

2. Undercoating, grease, or dirt buildup on the driveshaft can cause vibrations.
3. Undercoating should be removed using a suitable solvent and a rag. Always dispose of used rags properly.

The **U-joints** should be inspected every time the vehicle chassis is lubricated, or four times a year. Original equipment (OE) U-joints are permanently lubricated and have no provision for greasing. If there is a grease fitting, the U-joint should be lubricated by applying grease with a grease gun. ● **SEE FIGURES 124–2 AND 124–3**.

In addition to periodic lubrication, the driveshaft should be grabbed and moved to see if there is any movement of the U-joints. If *any* movement is noticed when the driveshaft is moved, the U-joint is worn and must be replaced.

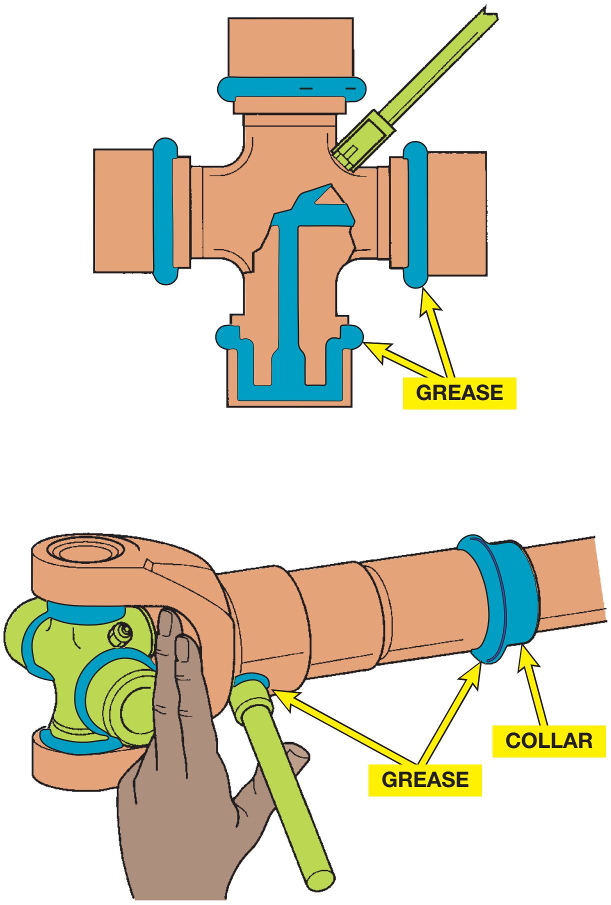

FIGURE 124–2 All U-joints and spline collars equipped with a grease fitting should be greased four times a year as part of a regular lubrication service.

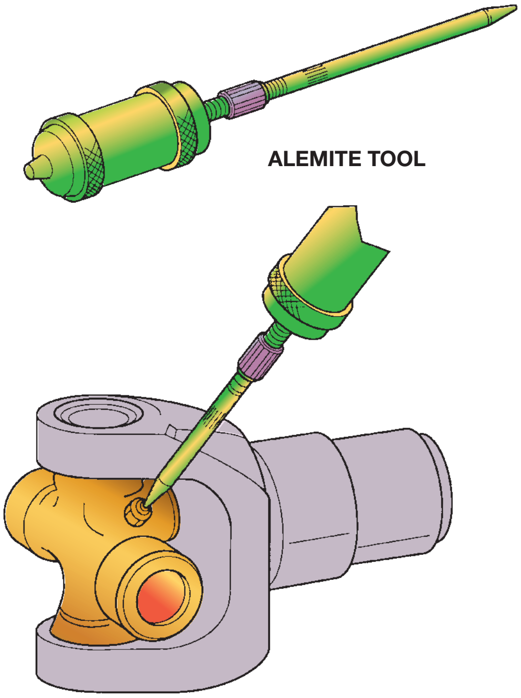

FIGURE 124–3 Many U-joints require a special grease gun tool to reach the grease fittings.

NOTE: U-joints are not serviceable items and cannot be repaired. If worn or defective, they must be replaced.

U-joints can be defective and still not show noticeable free movement. *A proper U-joint inspection can be performed only by removing the driveshaft from the vehicle*.

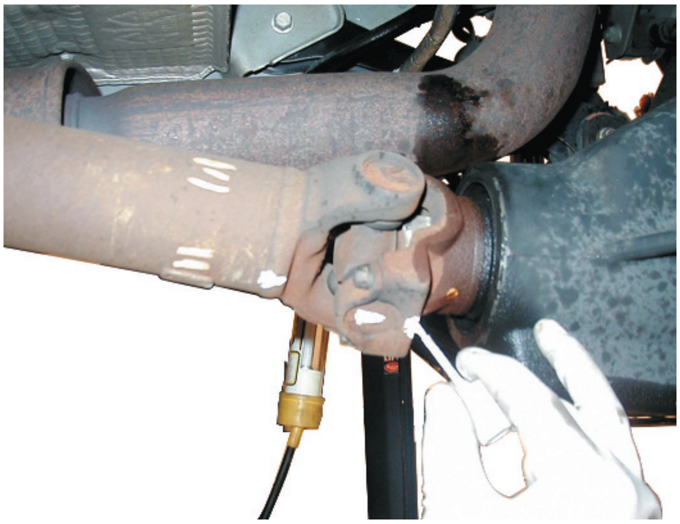

FIGURE 124–4 Always mark the original location of U-joints before disassembly.

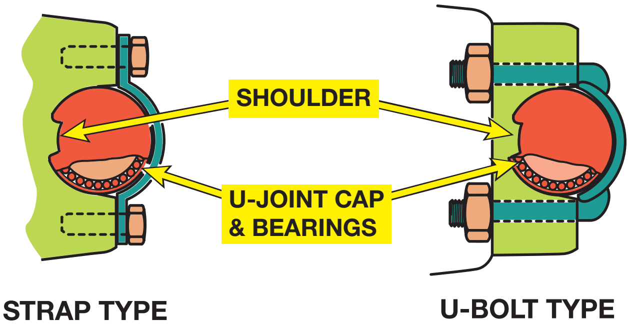

FIGURE 124–5 Two types of retaining methods that are commonly used at the rear U-joint at the differential.

Before removing the driveshaft, always mark the position of all mating parts to ensure proper reassembly. White correction fluid, also known as “White Out” or “Liquid Paper,” is an easy and fast-drying marking material. ● **SEE FIGURE 124–4**.

To remove the driveshaft from a rear-wheel-drive vehicle, remove the four fasteners at the rear U-joint at the differential. ● **SEE FIGURE 124–5**.

Push the driveshaft forward toward the transmission and then down and toward the rear of the vehicle. The driveshaft should slip out of the transmission spline and can be removed from underneath the vehicle.

NOTE: With the driveshaft removed, transmission lubricant can leak out of the rear extension housing. To prevent a mess, use an old spline the same size as the one being removed or place a plastic bag over the extension housing to hold any escaping lubricant. A rubber band can be used to hold the bag onto the extension housing.

To inspect U-joints, move each joint through its full travel, making sure it can move (articulate) freely and equally in all directions. ● **SEE FIGURE 124–6**.

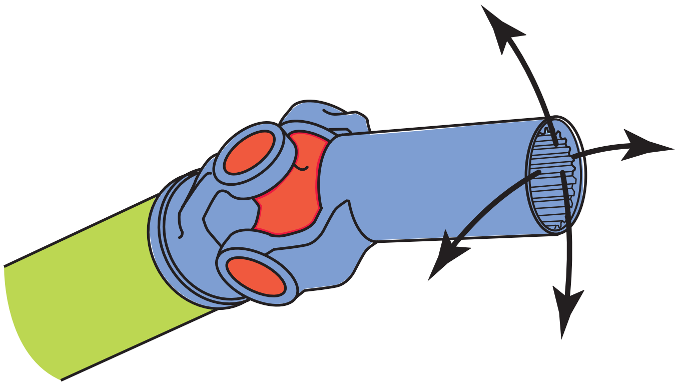

FIGURE 124–6 The best way to check any U-joint is to remove the driveshaft from the vehicle and move each joint in all directions. A good U-joint should be free to move without binding.

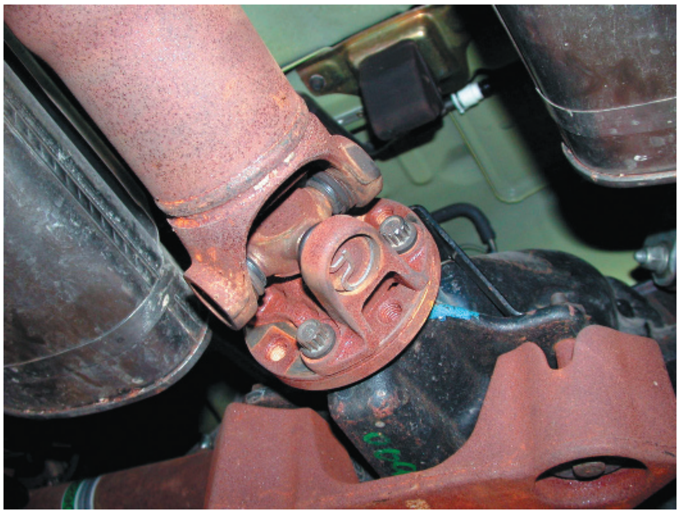

FIGURE 124–7 Typical U-joint that uses an outside snap ring. This style of joint bolts directly to the companion flange that is attached to the pinion gear in the differential.

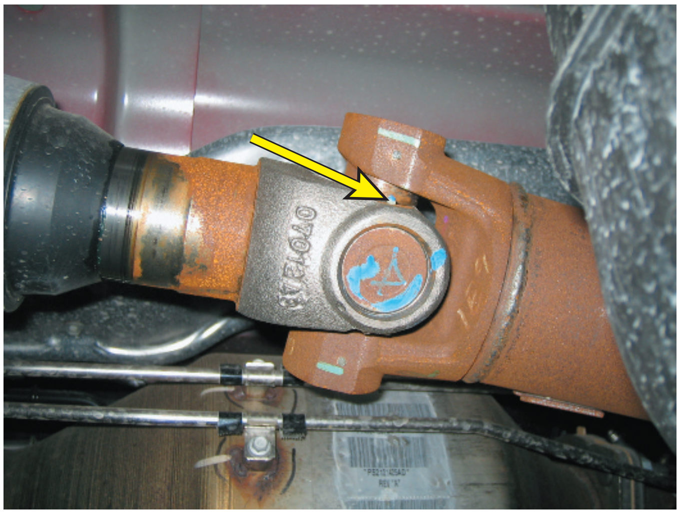

FIGURE 124–8 A U-joint that is held together by nylon and usually requires that heat be applied to remove from the yoke.

U-JOINT REPLACEMENT

All movement in a U-joint should occur between the trunnions and the needle bearings in the end caps. The end caps are press-fit to the yokes, which are welded to the driveshaft. Three types of retainers are used to keep the bearing caps on the U-joints: the outside snap ring (● **SEE FIGURE 124–7**), the inside retaining ring, and injected synthetic (usually nylon). ● **SEE FIGURE 124–8**.

After removing the retainers, use a press or a vise to separate the U-joint from the yoke. ● **SEE FIGURE 124–9**.

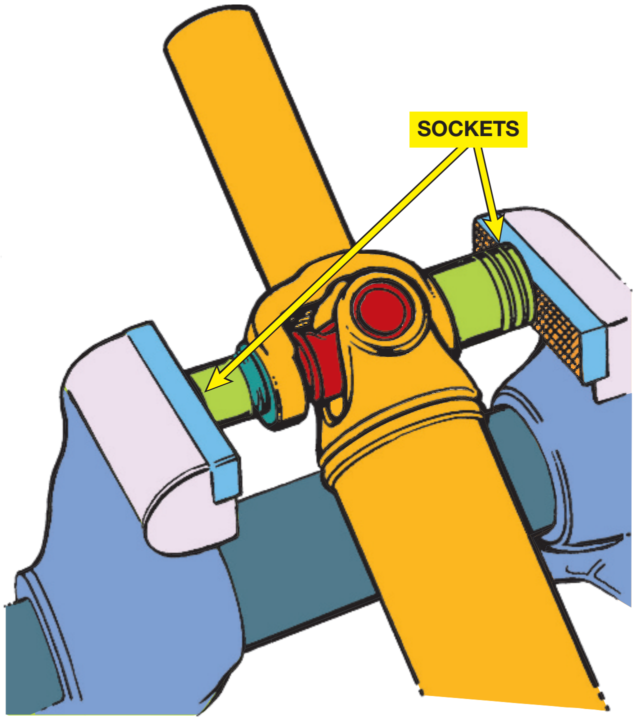

FIGURE 124–9 Use a vise and two sockets to remove a U-joint. One socket fits over the bearing cup and the other fits on the bearing to press-fit the cups from the crosspiece.

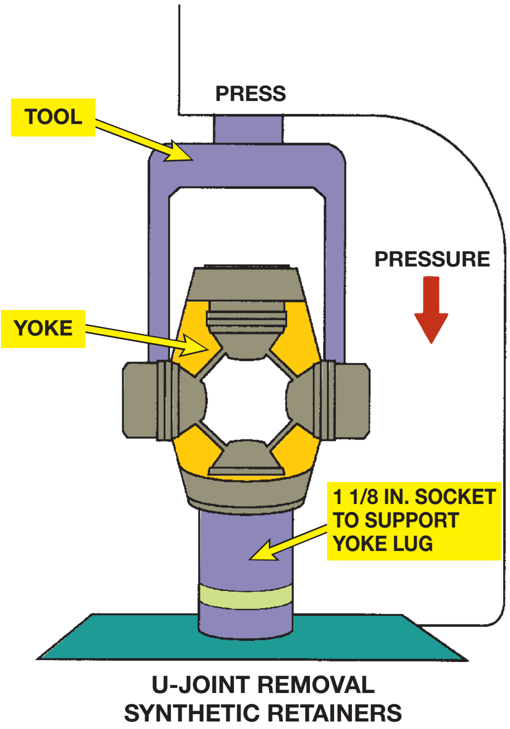

FIGURE 124–11 A special tool being used to press apart a U-joint that is retained by injected plastic. Heat from a propane torch may be necessary to soften the plastic to avoid exerting too much force on the U-joint.

TECH TIP

Use Tape to Be Safe

When removing a driveshaft, use tape to prevent the rear U-joint caps from falling off. If the caps fall off the U-joint, all of the needle bearings will fall out and scatter over the floor. ● **SEE FIGURE 124–10**.

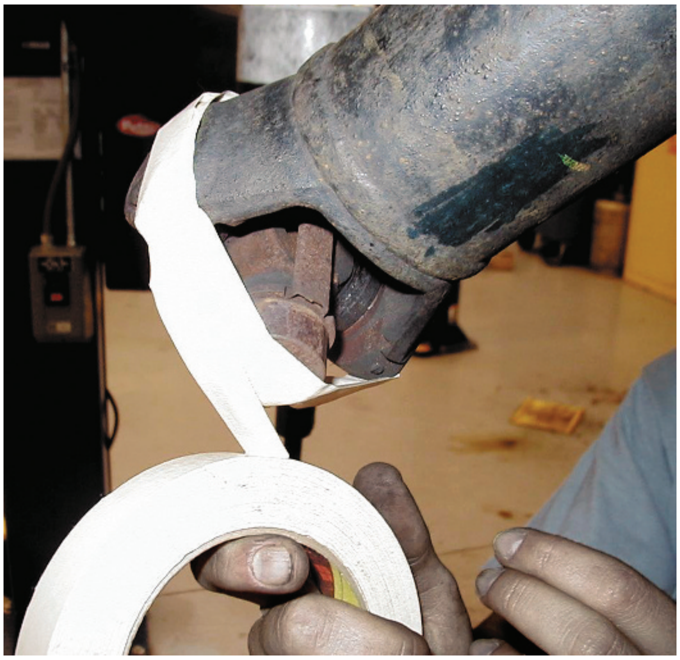

FIGURE 124–10 Taping the U-joint to prevent the caps from coming off.

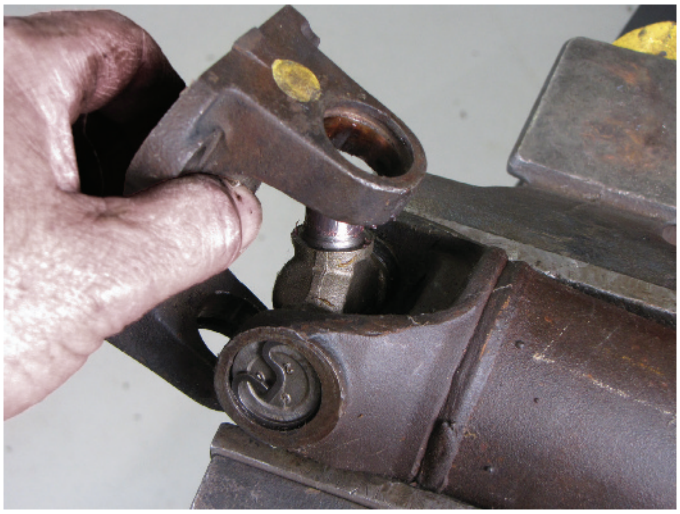

FIGURE 124–12 Removing the worn cross from the yoke.

U-joints that use **synthetic retainers** must be separated using a press and a special tool to press onto both sides of the joint in order to shear the plastic retainer, as shown in ● **FIGURE 124–11**.

Replacement U-joints use spring clips instead of injected plastic. Remove the old U-joint from the yoke, as shown in ● **FIGURE 124–12**, and replace with a new U-joint. Replacement U-joints should be *forged* (never cast) and use up to 32 needle bearings (also called **pin bushings**) instead of just 24 needle bearings, as used in lower-quality U-joints. Replacement U-joints usually have a grease fitting so that the new replacement U-joint can be properly lubricated. ● **SEE FIGURE 124–13**.

After removing any dirt or burrs from the yoke, press in a new U-joint. Rotate the new joint after installation to make sure it moves freely, without binding or stiffness. If a U-joint is stiff, it can cause a vibration.

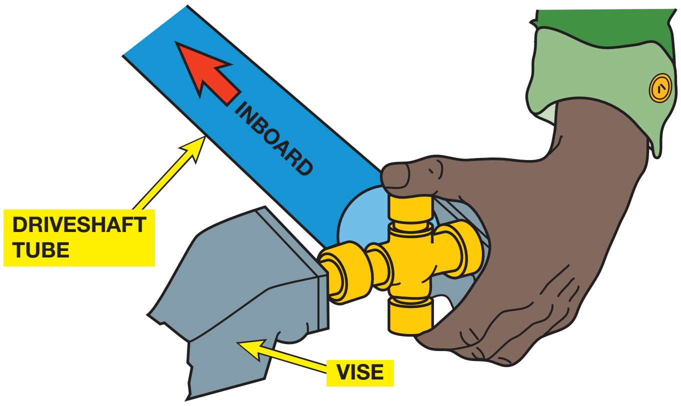

FIGURE 124–13 When installing a new U-joint, position the grease fitting on the inboard side (toward the driveshaft tube) and in alignment with the grease fitting of the U-joint at the other end.

NOTE: If a U-joint is slightly stiff after being installed, strike the U-joint using a brass punch and a light hammer. This often frees a stiff joint and is often called "relieving the joint." The shock aligns the needle bearings in the end caps.

U-JOINT WORKING ANGLES

Unequal or incorrect U-joint working angles can cause severe vibrations. Driveshaft and U-joint angles may change from the original factory setting due to one or more of the following:

1. Defective or collapsed engine or transmission mounts
2. Defective or sagging springs, especially the rear springs due to overloading or other causes
3. Accident damage or other changes to the chassis of the vehicle
4. Vehicle modification that raises or lowers the ride height

Replace any engine or transmission mount that is cracked or collapsed. When a mount collapses, the engine drops from its original location. Now the driveshaft angles are changed and a vibration may be felt.

Rear springs often sag after many years of service or after being overloaded. This is especially true of pickup trucks. Many people carry as much as the cargo bed can hold, often exceeding the factory-recommended carry capacity or gross vehicle weight (GVW) of the vehicle.

To measure U-joint and driveshaft angles, the vehicle must be hoisted using an axle contact or drive-on-type lift so as to maintain the same driveshaft angles as the vehicle has while being driven.

The working angles of the two U-joints on a driveshaft should be within 1/2 degree of each other in order to cancel out speed changes. ● **SEE FIGURE 124–14**.

To measure the working angle of a U-joint, follow these steps:

STEP 1 Place an **inclinometer** (a tool used to measure angles) on the rear U-joint bearing cap. Level the bubble and read the angle. ● **SEE FIGURE 124–15**; the pictured reading is 19.5 degrees.

STEP 2 Rotate the driveshaft 90 degrees and read the angle of the rear yoke. For example, this reading is 17 degrees.

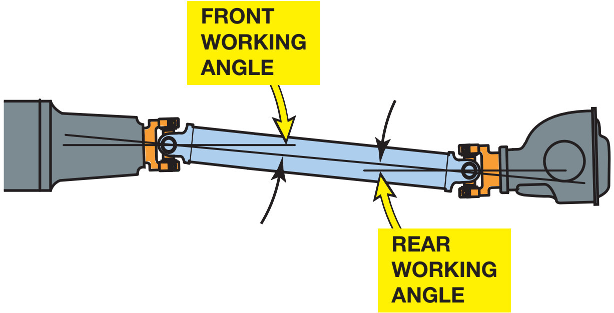

FIGURE 124–14 The working angle of most U-joints should be at least 1/2 degree (to permit the needle bearing to rotate in the U-joints) and should not exceed 3 degrees or a vibration can occur in the driveshaft, especially at higher speeds. The difference between the front and rear working angles should be within 1/2 degree of each other.

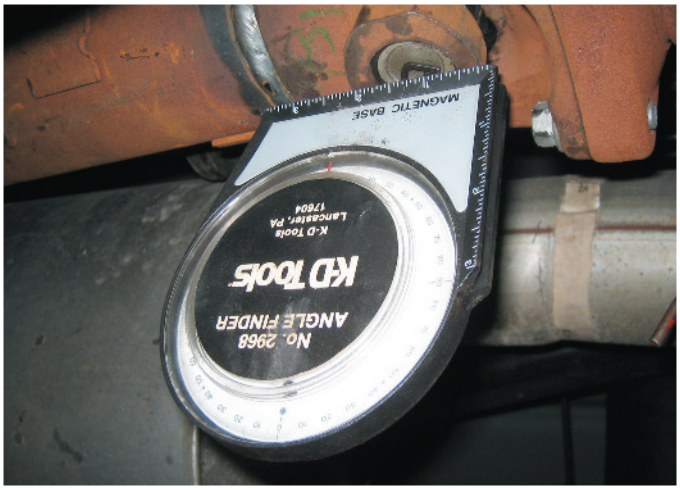

FIGURE 124–15 An inclinometer with a magnetic base is being used to measure the angle of the driveshaft at the rear U-joint.

STEP 3 Subtract the smaller reading from the larger reading to obtain the working angle of the joint. In this example, it is 2.5 degrees (19.5 degrees − 17 degrees = 2.5 degrees).

Repeat the same procedure for the front U-joint. The front and rear working angles should be within 0.5 degrees. If the two working angles are not within 0.5 degrees, shims can be added to bring the two angles closer together. The angle of the rear joint is changed by installing a tapered shim between the leaf spring and the axle, as shown in ● **FIGURE 124–16**.

CAUTION: Use caution whenever using wedges between the differential and the rear leaf spring to restore the correct U-joint working angle. Even though wedges are made to raise the front of the differential, the tilt often prevents rear-end lubricant from reaching the pinion bearing, resulting in pinion bearing noise and eventual failure.

The angle of the front joint is changed by adding or removing shims from the mount under the transmission. Sometimes the driveshaft working angles can change due to wear or failure of the engine or transmission mounts. ● **SEE FIGURE 124–17**.

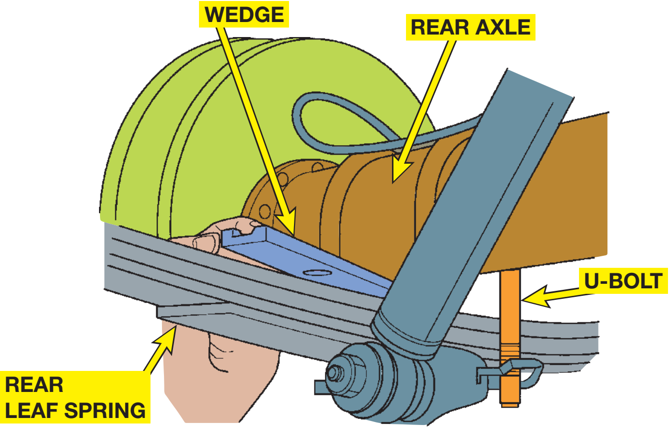

FIGURE 124–16 Placing a tapered metal wedge between the rear leaf spring and the rear axle pedestal to correct rear U-joint working angles.

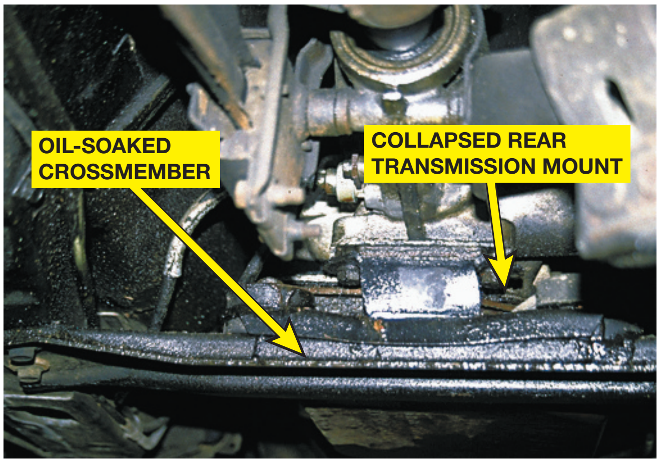

FIGURE 124–17 A transmission oil pan gasket leak allowed automatic transmission fluid (ATF) to saturate the rear transmission mount rubber, causing it to collapse. After replacing the defective mount, proper driveshaft angles were restored and the driveline vibration was corrected.

CV JOINT DIAGNOSIS

When a CV joint wears or fails, the most common symptom is noise while driving. An outer fixed CV joint will most likely be heard when turning sharply and accelerating at the same time. This noise is usually a clicking sound. While inner joint failure is less common, a defective inner CV joint often creates a loud clunk while accelerating from rest. To help verify a defective joint, drive the vehicle in reverse while turning and accelerating. This almost always will reveal a defective outer joint.

REPLACEMENT SHAFT ASSEMBLIES Front-wheel-drive vehicles were widely used in Europe and Japan long before they became popular in North America. The standard repair procedure used in these countries is the replacement of the entire drive assembly if there is a CV joint failure. Replacement boot kits are rarely seen in Europe because it is felt that even a slight amount of dirt or water inside a CV joint is unacceptable. Vehicle owners simply wait until the joint wear causes severe noise, and then the entire assembly is replaced.

The entire drive axle shaft assembly can easily be replaced and the defective unit can be sent to a company for remanufacturing. Even though cost to the customer is higher, the parts and repair shop does not have to inventory every type, size, and style of boot kit and CV joint. Service procedures and practices therefore vary according to location and the availability of parts. For example, some service technicians use replacement drive axle assemblies from salvage yards with good success.

NOTE: Some drive axle shafts have a weight attached between the inner and outer CV joints. This is a dampener weight. It is not a balance weight, and it need not be transferred to the replacement drive axle shaft (half shaft) unless instructed to do so in the directions that accompany the replacement shaft assembly.

TECH TIP

Quick and Easy Backlash Test

Whenever a driveline clunk is being diagnosed, one possible cause is excessive backlash (clearance) between the ring gear teeth and differential pinion teeth in the differential. Another common cause of excessive differential backlash is too much clearance between differential carrier pinion teeth and side gear teeth. A quick test to check backlash involves three easy steps:

STEP 1 Hoist the vehicle on a frame contact lift, allowing the drive wheels to be rotated.

STEP 2 Have an assistant hold one drive wheel and the driveshaft to keep them from turning.

STEP 3 Move the other drive wheel, observing how far the tire can rotate. This is the amount of backlash in the differential; it should be less than 1 inch (25 mm), of movement measured *at the tire.*

If the tire can move more than 1 inch (25 mm), then the differential should be inspected for wear and parts should be replaced as necessary. If the tire moves *less* than 1 inch (25 mm), then the backlash between the ring gear and pinion is probably *not* the cause of the noise.

CV JOINT SERVICE

The hub nut must be removed whenever servicing a CV joint or shaft assembly on a front-wheel-drive vehicle. Since these nuts are usually torqued to almost 200 lb-ft (260 N-m), keep the vehicle on the ground until the hub nut is loosened and then follow these steps (● **SEE FIGURE 124–18**):

STEP 1 Remove the front wheel and hub nut.

NOTE: Most manufacturers warn against using an air impact wrench to remove the hub nut. The impacting force can damage the hub bearing.

STEP 2 To allow the knuckle room to move outward enough to remove the drive axle shaft, some or all of the following will have to be disconnected:

a. Lower ball joint or **pinch bolt** (● **SEE FIGURE 124–19**).

b. Tie rod end (● **SEE FIGURE 124–20**).

FIGURE 124–20 The preferred method for separating the tie rod end from the steering knuckle is to use a puller such as the one shown. A "pickle-fork"-type tool should be used only if the tie rod is going to be replaced. A pickle-fork-type tool can damage or tear the rubber grease boot. Striking the tie rod end with a hammer while holding another hammer behind the joint to shock and break the taper from the steering knuckle can also be used.

c. Stabilizer bar link.

d. Front disc brake caliper.

STEP 3 Remove the splined end of the axle from the hub bearing. Sometimes a special puller may be necessary, but in most cases the shaft can be tapped inward through the hub bearing with a light hammer and a brass punch can be used. To protect the threads of the drive axle shaft, install the hub nut temporarily. ● **SEE FIGURES 124–21 AND 124–22**.

STEP 4 Use a prybar or special tool with a slide hammer, as shown in ● **FIGURE 124–23**, and remove the inner joint from the transaxle.

STEP 5 Remove the drive axle shaft from the vehicle. ● **SEE FIGURES 124–24 AND 124–25**.

STEP 6 Reinstall the drive axle shaft in the reverse order of removal, and torque the drive axle nut to factory specifications. ● **SEE FIGURE 124–26**.

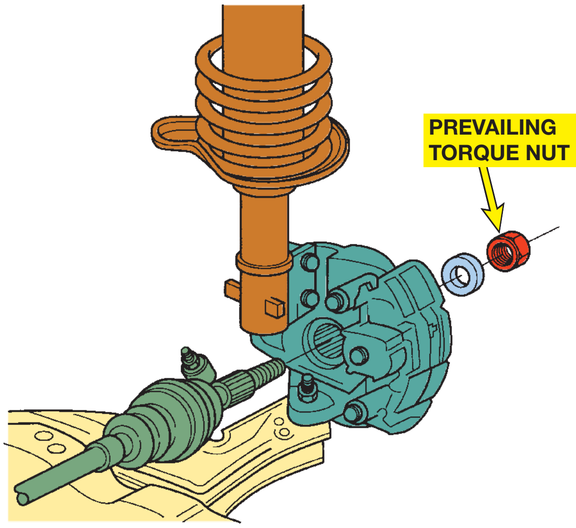

FIGURE 124–21 Many drive axles are retained by **prevailing torque nut** that must not be reused. Prevailing torque nuts are slightly deformed or contain a plastic insert that holds the nut tight (retains the torque) to the shaft without loosening.

TECH TIP

Spline Bind Cure

Driveline "clunk" often occurs in rear-wheel-drive vehicles when shifting between drive and reverse or when accelerating from a stop. Often the cause of this noise is excessive clearance in the differential. Another cause is called **spline bind**, where the changing rear pinion angle creates a binding in the spline when the rear springs change in height. For example, when a pickup truck stops, the weight transfers toward the front and unloads the rear springs. The front of the differential noses downward and forward as the rear springs unload. When the driver accelerates forward, the rear of the truck squats downward, causing the driveshaft to be pulled rearward when the front of the differential rotates upward. This upward movement on the spline often causes the spline to bind and make a loud clunk when the bind is finally released.

The method recommended by vehicle manufacturers to eliminate this noise is to follow these steps:

1. Remove the driveshaft.
2. Clean the splines on both the driveshaft yoke and the transmission output shaft.
3. Remove any burrs on the splines with a small metal file (remove all filings).
4. Apply a high-temperature grease to the spline teeth of the yoke. Apply grease to each spline, but do not fill the splines. Synthetic chassis grease is preferred because of its high temperature resistance.
5. Reinstall the driveshaft.

CASE STUDY

The Vibrating Buick

The owner of a front-wheel-drive Buick complained that it vibrated during acceleration only. The vehicle would also pull toward one side during acceleration. An inspection discovered a worn (cracked) engine mount. After replacing the mount, the CV joint angles were restored and both the vibration and the pulling to one side during acceleration were solved. ● **SEE FIGURE 124–27**.

Summary:

Complaint—Owner complained about a vibration and a pull to one side during acceleration.
Cause—A defective engine mount which caused the CV joint angles to be unequal, causing the vibration and pulling during acceleration.
Correction—The engine mount was replaced and the customer concern was solved.

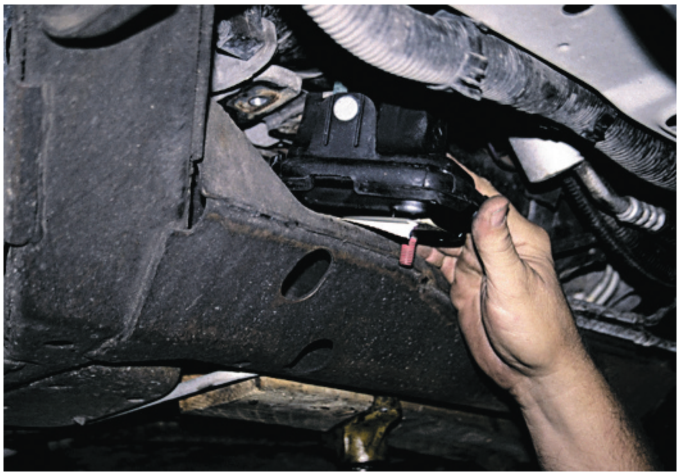

FIGURE 124–27 The engine had to be raised higher to get the new (non-collapsed) engine mount installed.

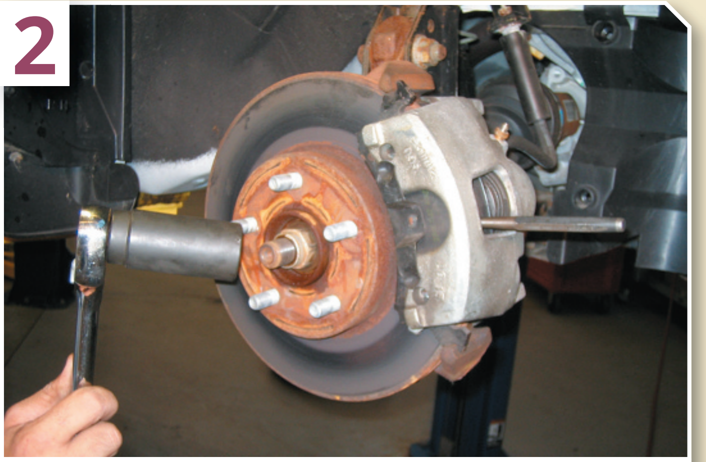
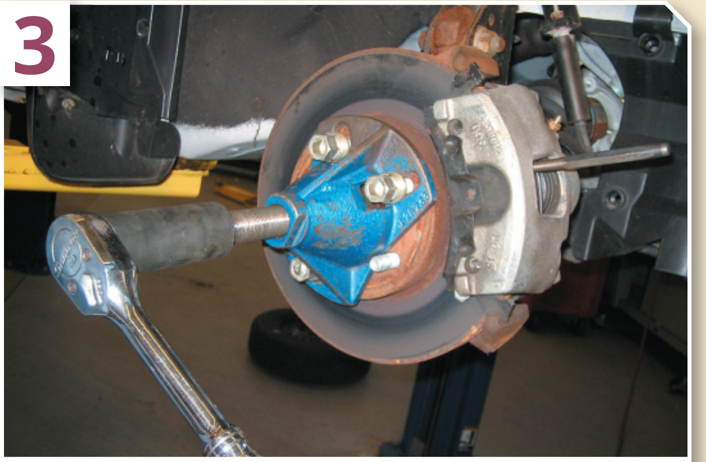
Tools needed to replace a drive axle shaft on a General Motors vehicle include a drift, sockets, plus a prybar bearing/axle shaft special tool.

2



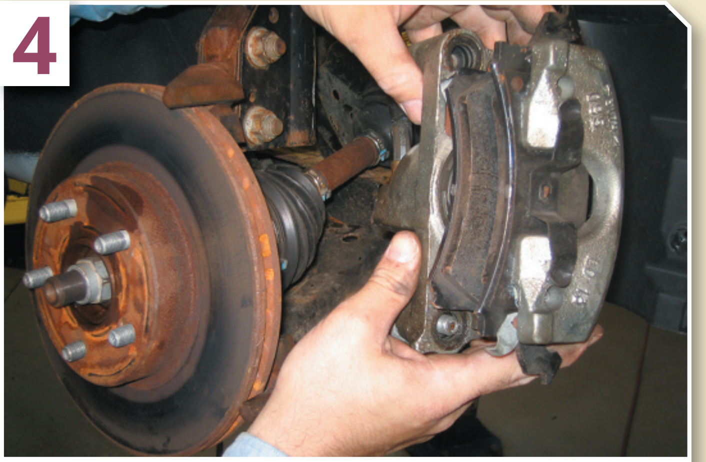
The drive axle shaft retaining nut can be loosened with the tire on the ground, or use a drift inserted into the rotor cooling fins before removing the nut.

3



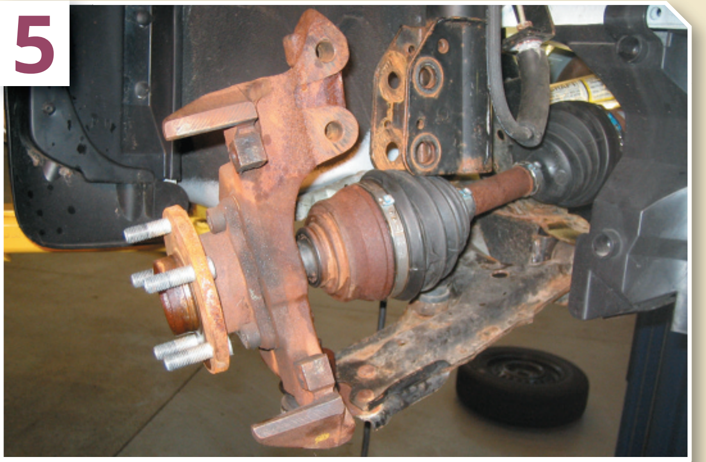
Using a special tool to push the drive axle splines from the bearing assembly.

4



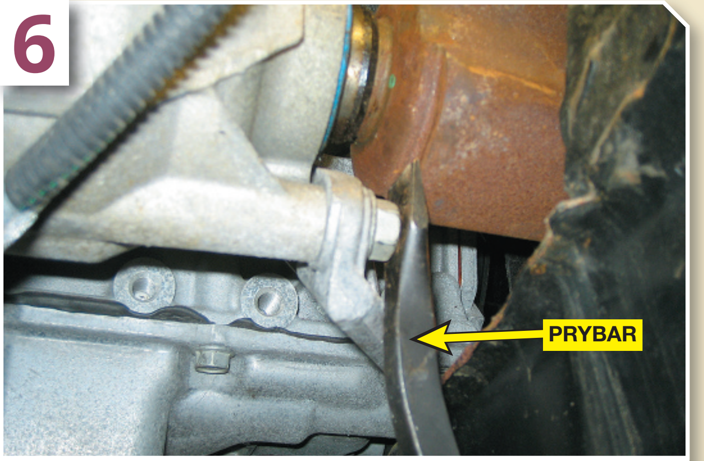
Remove the disc brake caliper and support it out of the way. Then, remove the disc brake rotor.

5



The lower ball joint could have been removed instead of disconnecting the strut from the knuckle so that the alignment could be retained.

6



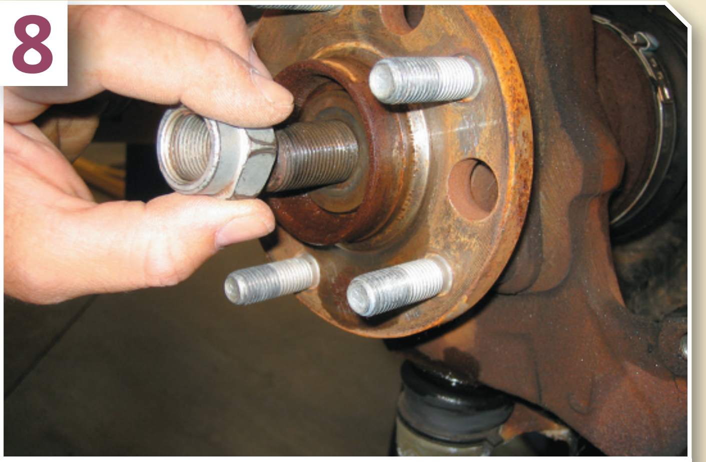
A prybar is used to separate the inner drive axle shaft joint from the transaxle.

DRIVE AXLE SHAFT REPLACEMENT

7

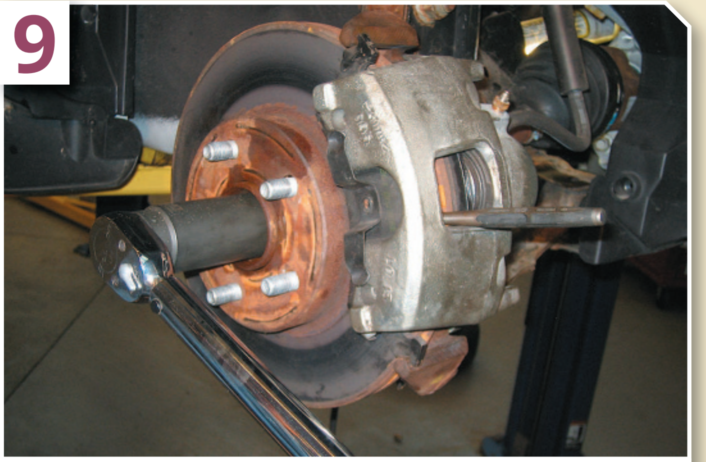
After the inner joint splines have been released from the transaxle, carefully remove the drive axle shaft assembly from the vehicle.

8



To install, reverse the disassembly procedure and be sure to install the washer under the retainer-nut, and always use a new prevailing torque nut.

9



Reinstall the disc brake rotor and caliper and then torque the drive axle shaft retaining nut to factory specifications.

REVIEW QUESTIONS

1. What two items should be checked when inspecting a driveshaft?
2. What steps are necessary to measure driveshaft U-joint working angles?
3. What is the procedure for replacing a Cardan-type U-joint?
4. How is a CV joint replaced?
5. What is a prevailing torque nut?

CHAPTER QUIZ

1. Two technicians are discussing U-joints. Technician A says that a defective U-joint could cause a loud clunk when the transmission is shifted between drive and reverse. Technician B says a worn U-joint can cause a clicking sound only when driving the vehicle in reverse. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
2. A Cardan-type U-joint may require what tool(s) to replace?
   - **a.** A special tool
   - **b.** A torch
   - **c.** A press or a vise
   - **d.** May require any of the above
3. Incorrect or unequal U-joint working angles are most likely to be caused by _____________.
   - **a.** a bent driveshaft
   - **b.** a collapsed engine or transmission mount
   - **c.** a dry output shaft spline
   - **d.** defective or damaged U-joints
4. Front and rear driveshaft U-joint working angles should be within _____________ degrees of each other.
   - **a.** 0.5
   - **b.** 1.0
   - **c.** 3.0
   - **d.** 4.0
5. What could be a symptom of a defective U-joint?
   - **a.** A vibration at highway speed
   - **b.** A clicking sound
   - **c.** A clunking sound
   - **d.** Any of the above
6. A defective outer CV joint will usually make a _____________.
   - **a.** rumbling noise
   - **b.** growling noise
   - **c.** clicking noise
   - **d.** clunking noise
7. What can be used to correct U-joint working angles?
   - **a.** A turnbuckle
   - **b.** A wedge
   - **c.** An adjustable shock absorber
   - **d.** Welded spring mounts
8. What needs to be removed to replace a drive axle shaft from a front-wheel-drive vehicle?
   - **a.** Tie rod end
   - **b.** Lower control arm or ball joint
   - **c.** Hub nut
   - **d.** All of the above
9. The splines of the driveshaft yoke should be lubricated to prevent _____________.
   - **a.** a vibration
   - **b.** spline bind
   - **c.** rust
   - **d.** transmission fluid leaking from the extension housing
10. What is recommended to install the drive axle shaft to avoid damage to the hub bearing?
    - **a.** Torque wrench
    - **b.** Cordless impact wrench
    - **c.** Pickle fork
    - **d.** Hub bearing puller

DRIVE AXLES AND DIFFERENTIALS

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Describe the purpose and function of a drive axle.
- Describe the parts of a drive axle.
- Describe drive axle gear ratios.
- Discuss open differentials.
- Discuss limited slip differentials.
- Describe the components of a drive axle.
- Describe rear axle bearings.
- Explain how to identify drive axles.
- Explain how to determine the axle ratio.
- Discuss rear-end noise diagnosis.
- Discuss drive axle inspection.
- Discuss drive axle disassembly.
- Explain how to replace the pinion shaft bearing.
- Explain how to set the drive pinion depth.
- Discuss how to set the preload for pinion gears.
- Describe the procedure to check and correct backlash.
- Discuss how to set the preload for side bearings.
- Discuss drive axle reassembly.
- Discuss drive axle lubricants.

DRIVE AXLES

TERMINOLOGY All rear-wheel-drive (RWD) vehicles use a drive axle assembly to transfer power from the drive shaft to the drive wheels. Because it is powered, it is sometimes called a **live axle**.

Front-wheel-drive (FWD) cars use a dead axle or non-powered rear axle. The major parts of a drive axle include

- Ring and pinion gears
- Differential
- Axle shafts

PURPOSE AND FUNCTION The purpose and function of a drive axle assembly include the following:

- To change the direction of engine torque (● **SEE FIGURE 125–1**.)
- To allow the drive wheels to rotate at different speeds (● **SEE FIGURE 125–2**.)

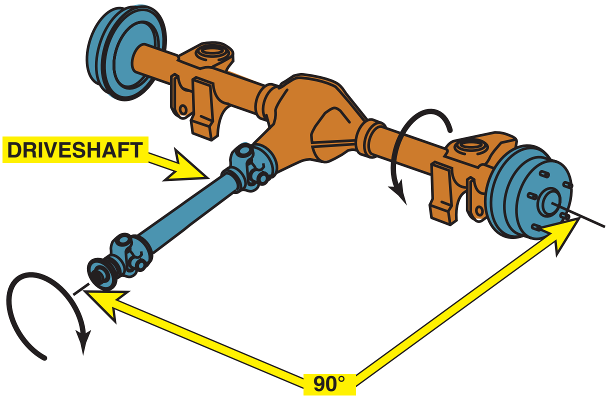

FIGURE 125–1 The differential assembly changes the direction of engine torque and increases the torque to the drive wheels.

FIGURE 125–3 When the vehicle turns a corner, the inner wheel slows and the outer wheel increases in speed to compensate. This difference in rotational speed causes the pinion gears to "walk" around the slower side gear.

A differential is a mechanical addition and subtraction assembly. By splitting the engine torque to the drive wheels when the vehicle is turning a corner, the torque forces cause the side gear and pinion gears to subtract torque from one side and add torque to the opposite side. ● **SEE FIGURE 125–3.**

NOTE: The differential used in most front-wheel-drive vehicles is incorporated into the transaxle assembly and is called the final drive assembly. The purpose and function of this final drive assembly is similar to the differential assembly used in rear-wheel-drive vehicles.

PARTS OF A DRIVE AXLE

A drive axle is also called a **rear end** or abbreviated simply as a **diff**. Whenever any vehicle makes a turn, the outside wheel must travel a greater distance than the inside wheel. The driveshaft applies torque to the **drive pinion gear** that meshes below the center line of a **ring gear** as shown in ● **FIGURE 125–4**. This type of gear set is called a **hypoid gear set** and requires gear lubrication specifically designed for this type of service. The ring gear is attached to a **differential case** that also contains small beveled **spider gears** or **pinion gears**. A **pinion shaft** passes through the two pinion gears in the case. In mesh with the pinion gears are two **side gears** that are splined to the inner ends of the axles. ● **SEE FIGURE 125–5.**

DIFFERENTIAL CARRIER BEARINGS

FIGURE 125–5 A pair of tapered roller bearings called carrier bearings is used to locate the drive pinion gear and the differential case and ring gear. Another pair of bearings locates the drive pinion gear.

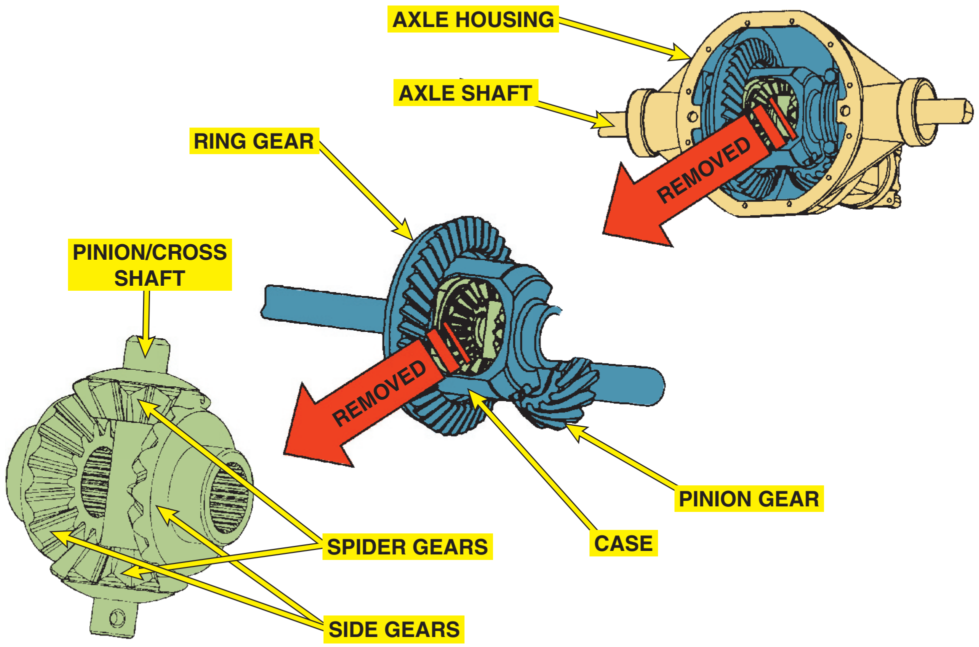

FIGURE 125–6 The relationship among the ring gear and drive pinion as well as the side and spider gears.

THE PINION AND RING GEARS DURING OPERATION During operation, the position of the drive pinion gear on the ring gear changes. The ring gear mounts onto the differential case as shown in ● **FIGURE 125–6**. Each slanted ring gear tooth has two ends. Its **toe** is closest to the ring gear center; its **heel**, closest to the outside circumference. The tooth **root** is the depression lying between two teeth, and the **crown** is the very top of each tooth.

While a vehicle accelerates, the drive pinion contacts the ring teeth on its **drive, or convex side**. While decelerating, the drive pinion contacts the ring teeth on its **coast, or concave side**. ● **SEE FIGURE 125–7**. The intermediate position between drive and coast, when neither the ring gear nor the pinion is driving each other, is called the **"floating" position**.

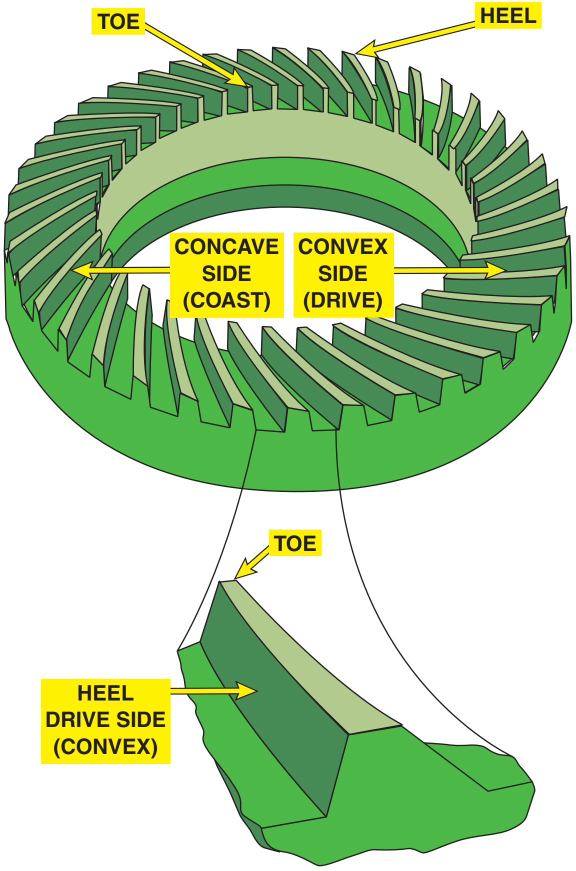

FIGURE 125–7 The drive side is the convex side of the ring gear except for some front axles used in four-wheel vehicles, and they often use the concave side on the drive side.

DRIVE AXLE GEAR RATIOS

The final gear reduction in the drive train occurs in the drive axle assembly. The amount of torque a gear set delivers depends on the gear ratio between the drive pinion gear and the driven ring gear. The gear ratio of the final drive (differential) is called the **axle ratio**. To determine the axle ratio, divide the number of teeth of the ring gear (driven gear) by the number of teeth of the drive pinion gear (driving gear):

$$\frac{\textbf{Ring gear (41 teeth)}}{\textbf{Pinion gear (10 teeth)}} = \textbf{4.10 (Axle ratio)}$$

The higher the axle ratio number, the faster the engine rotates for each rotation of the drive wheels. See the High-Performance Tip "Change the Axle Ratio."

RING AND PINION GEAR SET TYPES The final drive gear ratio determines how many times a drive pinion tooth will make contact with a particular ring gear tooth during one revolution. This affects final drive gear set manufacture and service.

Final drive gear sets may be divided into three types, depending on the final drive gear ratio.

1. **Hunting gear sets** are gear sets with final drive ratios expressible in a fraction that cannot be reduced to any lower terms. An example of a hunting gear set is one that has 41 teeth on the ring gear and 11 teeth on the drive pinion. This combination creates a 3.73:1 axle ratio. This type of gear set requires no timing marks or alignment during assembly. As the pinion gear drives the ring gear, each pinion tooth will hunt for, or seek, contact with every ring gear tooth.

2. **Nonhunting gear sets** are gear sets with final drive ratios expressible as a whole number. An example of a nonhunting gearset is a differential that uses 39 teeth on the ring gear and 13 teeth on the pinion gear, which gives a 3.00:1 gear ratio. Nonhunting gear sets require timing marks. As the pinion gear drives the ring gear, each pinion tooth contacts only a few ring gear teeth during each revolution.
3. **Partially nonhunting gear sets** are gear sets with final drive ratios expressible as a reducible fraction not equaling a whole number. An example of a partial nonhunting gearset is an axle ratio of 3.50:1.

Partially nonhunting gear sets also require timing marks. During final drive operation, each pinion tooth contacts only some of the ring pinion teeth. For the pinion teeth to make contact with the highest number of ring gear teeth, the pinion gear must drive the ring gear more than one revolution.

On nonhunting and partially nonhunting gears, manufacturers **lap** the contacting gear teeth to decrease wear. For this reason, these gear sets are marked to ensure proper alignment during assembly procedures. To preserve the wear patterns, the gear sets should be reassembled using the same alignment. This prolongs the life of the gear set and decreases operational noise.

HIGH PERFORMANCE TIP

Change the Axle Ratio

To increase vehicle performance, replace a high ratio (lower number) rear axle ratio with a lower ratio (higher number) rear axle. For example,

Stock rear end = 3.23:1 (drive pinion has 13 teeth and the ring gear has 42 teeth)

Replacement rear end = 3.73:1 (drive pinion has 11 teeth and the ring gear has 41 teeth)

The high-performance axle ratio (3.73:1) allows the engine to rotate faster than the stock 3.23:1 ratio. Because most engines produce greater torque with increasing RPM (up to a point), this allows more torque to be applied to the drive wheels. Not only is the engine producing more torque, but the higher-number gear ratio also multiplies the available torque times 3.73 instead of the original 3.23. However, there are several disadvantages associated with changing the rear end ratio:

- Decreased fuel economy
- Incorrect speedometer and odometer readings that can affect the shifting of the automatic transmission unless changes are made to the computer or vehicle speed sensors
- Increased engine noise due to the higher engine speed
- Increased engine wear, again due to the increased engine speed

If you can live with these disadvantages, a change in the rear end ratio generates a real performance gain.

OPEN DIFFERENTIALS

PURPOSE AND FUNCTION While a vehicle travels straight ahead, the speed of each driven wheel must be allowed to vary slightly as they go over bumps, potholes, railroad tracks, and other road surface irregularities. While cornering, the wheels must be able to turn at much greater differences in speed. Without some mechanism to allow for a difference in speed between the wheels, the left wheel would skid through the turn.

Inside the differential gear housing four to six bevel gears help drive the axles. In most differentials, there are two bevel gears called pinions that are constantly meshed with a beveled axle side gear on each axle. The pinion and axle side gears are contained in a housing called the carrier or case.

TORQUE FLOW THROUGH A STANDARD OPEN DIFFERENTIAL

Open differentials deliver equal torque to both wheels at all times. As the case rotates (driven by the engine through the ring and pinion gears), the cross-shaft applies a drive force to the spider gears. The two side gears apply reaction forces that counter this drive force. ● **SEE FIGURE 125–8**. Because the spider gear is free to rotate about the cross-shaft, the two reaction forces are equal. As the side gear applies a force to the spider gear, the spider gear applies an equal and opposite force to the side gear. It is this force, on the side gear, that supplies the torque to the axle that drives the wheel. Because the force on each side gear is equal, the torque supplied to each wheel is also equal. This is true regardless of whether one wheel is rotating faster than the other or at the same speed.

TRAVELING STRAIGHT-AHEAD Assuming that a vehicle has equal traction at both wheels, differential action does not occur. In other words, when traveling straight on smooth road surfaces the ring gear, carrier, and the drive axles are traveling at the same speed; they rotate as a unit and the spider gears are not rotating on the cross shaft.

TRAVELING AROUND CORNERS The ability of the differential pinion gears to spin on their shafts allows each axle to rotate at a different speed.

Case speed is always equal to the average speed of the two side gears. Since the ring gear rotates with the case and each

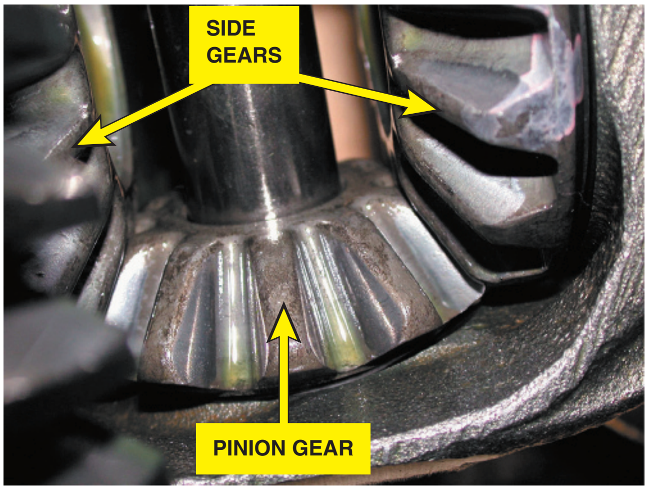

FIGURE 125–8 A close-up view of the side gears and spider (pinion) gear. Note the ridges on the gear teeth. These ridges are manufactured into the gear teeth to help retain lubricant so that no metal-to-metal contact occurs.

side gear rotates with its axle, when a vehicle corners, the outside wheel gains the same number of RPMs that the wheel on the inside loses, while ring gear RPM remains constant.

LIMITED SLIP DIFFERENTIALS

PURPOSE AND FUNCTION When a vehicle equipped with a standard differential spins a tire, the opposite wheel does not receive enough torque to move the vehicle. To solve this problem, most manufacturers use differentials that direct more power to the side gear attached to the spinning axle. Many differentials do this by forcing the side gear against the revolving case. This bypasses differential action, allowing the case to drive the side gear directly.

A limited-slip differential distributes torque to both wheels equally or unequally, allowing the wheels to turn at the same or at different speeds. ● **SEE FIGURE 125–9**.

The only means of having the standard differential apply different amounts of torque to each axle is to have the case drive the side gear directly, bypassing the pinion gears. One means of accomplishing this is to literally "push" the side gear out of mesh with the pinion gears against the rotating case.

PARTS AND OPERATION **Preloaded clutches** use two mechanisms to accomplish this action. First, a coil, Belleville, or leaf spring applies a force against the two side gears. ● **SEE FIGURE 125–10**. Second, a multidisc clutch pack or cones lie behind one or both of the side gears. Vehicle manufacturers refer to these differentials using various brand names, such as Positive Traction, Sure-Grip, Anti-Spin, and Traction-Lok.

When forces inside the differential push the side gear against the case, the clutch pack allows the gear to lock smoothly without jerking. The pack, lying between at least one of the backs of the side gears and the case, consists of two types of alternatively stacked steel discs with holes through their middle sections. The first is coated with friction material and the second is not. The interior splines of the friction disc holes mesh with the splines on the center hub protruding from the backside of the side gear. The holes of the steel discs are not splined. Instead, they have two or three tabs along their outside diameter that fit into slots machined into the differential case.

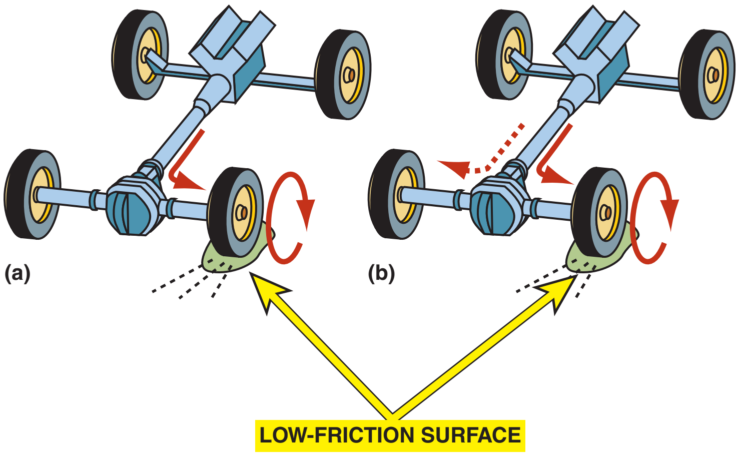

FIGURE 125–9 (a) A two-wheel-drive vehicle equipped with an open differential. (b) A two-wheel-drive vehicle equipped with a limited-slip differential.

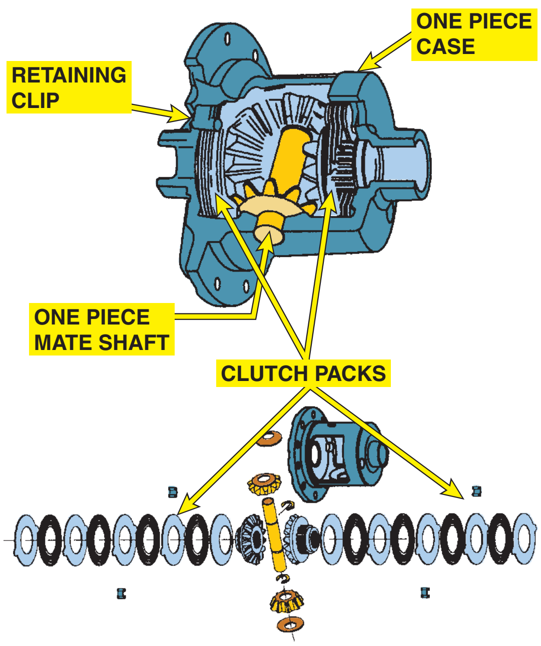

FIGURE 125–10 Trac-loc limited-slip differential. This type of limited-slip differential uses the preload force from a spring and the torque generated by the side gears as the two axles rotate at different rates to apply the clutches and limit the amount of difference in the speed of two axles.

As the side gear is pushed farther against the case, each friction plate rubs against the steel plate in front of and behind it, gradually slowing the side gear's rotation until it smoothly locks against the case.

1. The rotating differential pinions apply pressure against the side gear. The amount of pressure depends on the traction beneath the tire connected to the side gear.
2. The spring applies the second force that allows the preloaded clutch to work. This spring, whether a coil, leaf, or Belleville, preloads the clutch discs, narrowing the clearances between them. Tighter springs cause the differential to lock up sooner than looser springs.

To vary the amount of traction a tire must have before its axle's side gear locks up, many differentials use adjustment shims. Available in different thicknesses, manufacturers install them between the rear of the clutch packs and the differential case. The thicker the shims, the sooner the differential locks up. Some differentials rely on the preload spring alone to determine when the side gear locks up. They use no shims.

During operation, the clutch discs slide against each other every time the vehicle turns and corners. This action creates friction, making it important to add the manufacturer-recommended lubricant that contains a friction modifier. This lubricant may already be included in the gear oil or may be a special additive. Using improper lubricants may cause the discs to wear prematurely and vibrate during turns.

CONE-TYPE The second type of preloading clutch differential uses two tapered cones instead of multidisc clutch packs. Positioned between the side gears and the case, the cone's tapered end fits inside a dished receptacle machined into the case. The same forces that push the side gears against the case in the clutch pack differential push the side gears against the case in the tapered-cone differential. When these forces press the cones into their dished receptacles, they come to a stop smoothly, locking the side gears to the case.

VISCOUS COUPLED LIMITED-SLIP UNITS Differentials can be designed to work on the principle of a **viscous coupling**. This design uses a series of closely positioned plates, which do not physically touch one another. Half of the plates are splined to the case, and the other half are alternately splined to each side gear. The plates are housed in a sealed chamber, which is filled with a thick and viscous silicone-based fluid. The silicone allows normal speed differences between two shafts, resisting high-speed differences associated with wheel spin on one shaft.

This type of viscous-coupled differential is used in the front differentials of some Japanese front-wheel-drive vehicles and in four-wheel-drive vehicles.

THE EATON "LOCKER" DIFFERENTIAL The Eaton locker's sturdier design makes it more efficient in transferring torque from the driveline to the axles while in the locked position than the clutch-type multidisc differential.

When a vehicle spins a rear wheel, both the preloaded multidisc differential and the Eaton "locker" compress their clutch packs lying between the side gears and the case. This allows the case to directly drive the axles, bypassing the effect of the rotating differential pinions.

The Eaton and preloaded multidisc differentials differ in how they compress their clutch packs. The preloaded multidisc uses either a coil, leaf, or Belleville spring to apply initial pressure against the side gears and the clutch pack. As the rotating pinion gears push against a slower moving side gear, it is forced against the case, thereby compressing the discs in the clutch pack together.

The Eaton differential, on the other hand, uses a unique mechanism to collapse the clutch packs. ● **SEE FIGURE 125–11**. It has four parts:

- A governor with two flyweights
- A cam plate and cam side gear on the left side
- A latching bracket
- A thrust block

These parts allow the Eaton to momentarily shift into the locked mode when side gear and case rotational speeds differ by more than 100 RPM.

TORSEN DIFFERENTIALS The Torsen differential is a torque sensing, locking design that uses a set of worm side gears in mesh with individual worm wheel pinions that are supported by the differential case. ● **SEE FIGURE 125–13**. The pinions have spur gear sections machined on them at each end, which form the connection between left- and right-side pinions. Because of the worm and worm wheel configurations, the side gears can turn the pinions, but the pinions cannot turn the side gears. The result is a complex operation, which meets all drive requirements without excessive wheel slip.

This unit has been available as original equipment on several vehicles as well as for many aftermarket applications.

CASE STUDY

I Used to Have a Limited-Slip Differential

An owner of a Chevrolet S-10 pickup truck equipped with a V-6 and five-speed manual transmission complained that he used to be able to spin both rear tires on dry pavement, but lately only one tire spins. The service technician assigned to the repair order was very familiar with what might have occurred. Many General Motors pickup trucks are equipped with an Eaton locking differential that uses a torque-limiting disc. The teeth of this disc are designed to shear to prevent the possibility of breaking an axle. ● **SEE FIGURE 125–12**.

The service procedure to correct the customer's concern is to replace the left-hand clutch plates. Usually, the shearing of the torque-linking teeth is associated with a loud bang in the rear axle. The differential will continue to operate normally as a standard (open) differential.

Summary:

Complaint—Customer complained that the truck used to spin both rear tires when accelerating rapidly from a stop, but now only one tire spins.
Cause—The torque-limiting disc in the differential had sheared.
Correction—The left-hand clutch discs were replaced, which restored proper limited-slip differential operation.

DRIVE AXLE COMPONENTS

DRIVE PINIONS The drive pinion gear of the drive axle is driven by a flange often called a **companion flange**. The heavy bulk of the companion flange helps dampen vibrations and absorb shocks in the driveline. ● **SEE FIGURE 125–14**. The final drive pinion shaft may be supported by bearings using one of two methods.

1. The first method, and most common, uses two opposed taper roller bearings, with a collapsible (compressible) spacer separating the two inner races to support an overhung pinion. ● **SEE FIGURE 125–15**. The term "overhung" means all of the bearings supporting the pinion shaft lie on one side of the pinion gear. The bearings are preloaded, a state that minimizes wobble and endwise movement while the drive pinion shaft rotates.

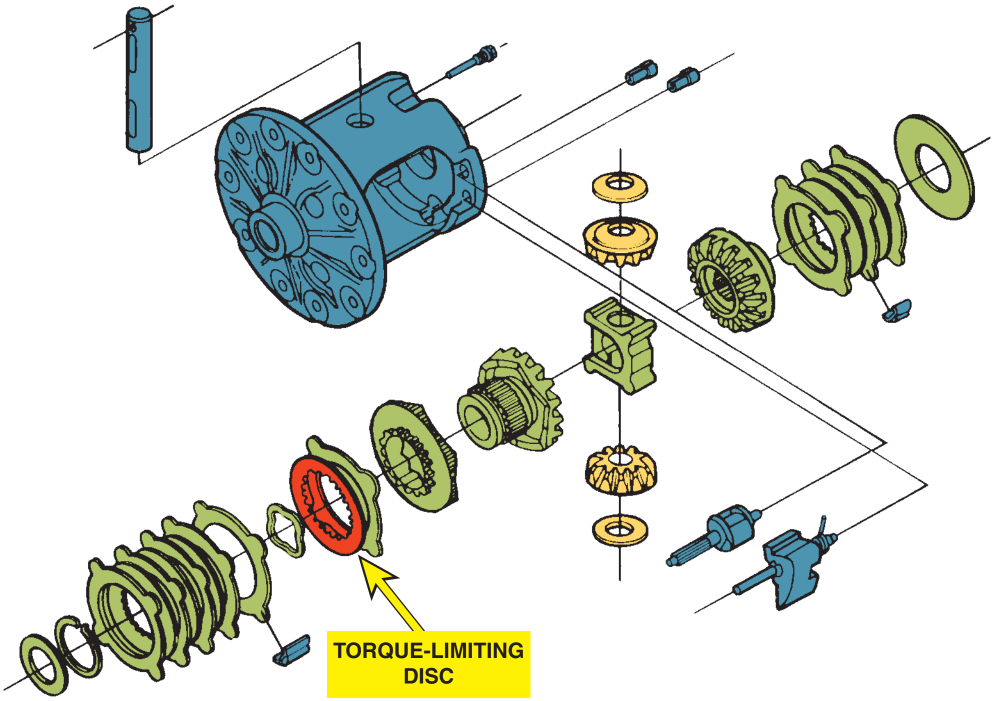

FIGURE 125–12 This Eaton design differential uses a torque-limiting disc to prevent the possibility of breaking an axle in the event of a high-torque demand. When the disc tangs shear, the differential will continue to function but as an open rather than as a limited-slip differential.

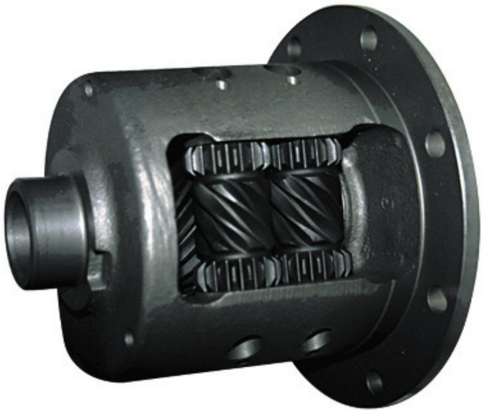

FIGURE 125–13 A Torsen differential. This type of differential provides torque to both drive wheels even if one tire is on ice. The complex system of gears allows this smooth transfer of torque without the use of clutches.

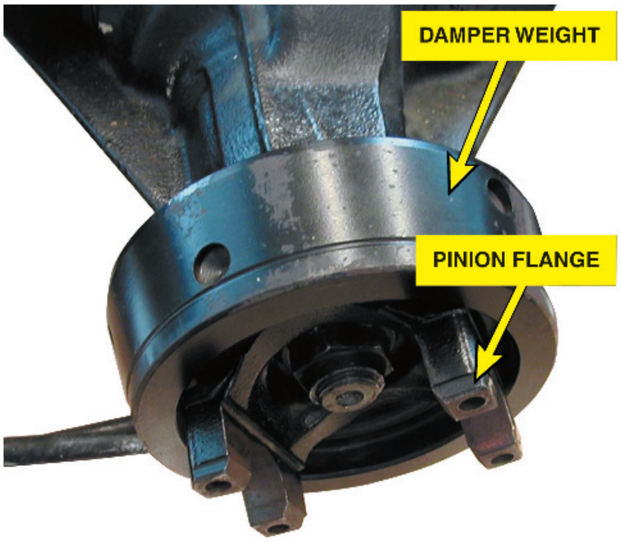

FIGURE 125–14 This pinion flange is equipped with a damper weight to help dampen driveline vibrations.

2. The second method uses two opposed taper roller bearings to support a **straddle-mounted pinion**, but the distance between them is smaller than in the overhung design. Most noticeably, a third smaller bearing attaches to a stemlike machined pilot protruding from the gear-end of the drive pinion shaft. This third bearing, usually a straight roller type, fits into a bore in the carrier. Unlike the overhung design, bearings supporting a straddle-mounted pinion lie on both sides of the pinion gear. Like the overhung design, a straddle-mounted pinion shaft usually has a compressible preloaded spacer positioned between the two larger differential case bearings. Straddle-mounted pinions are usually mounted in a pinion housing that can be removed from the carrier.

DRIVE PINION GEAR DEPTH The pinion shaft mounting method also determines how deeply the pinion gear meshes into the ring gear. This is called pinion depth and helps adjust the precise gear tooth relationship between the ring and pinion gears. You can vary the pinion depth adjustment by changing the thickness of a shim (spacer). This shim is located between the rear preloaded bearing and the pinion gear, or between the removable pinion housing and the carrier.

SIDE BEARINGS The differential case is supported by two side bearings pressed onto its sides. ● **SEE FIGURE 125–16**. These are usually tapered roller bearings and are preloaded to ensure case rotation without axial or radial movement.

Side bearing preload is adjusted either by threaded adjusting nuts as shown in ● **FIGURE 125–17** or by placement of adjusting shims (spacers) on either side of the case between the bearing outer races and the inside of the carrier. The method used to adjust side bearing preload is also used to adjust ring

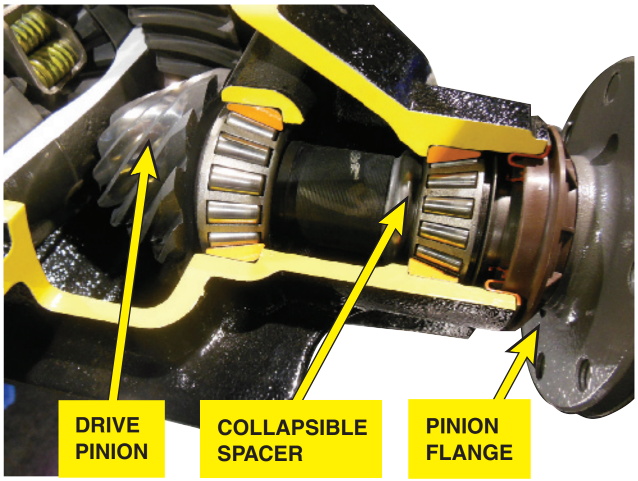

FIGURE 125–15 A collapsible spacer-type drive pinion shaft.

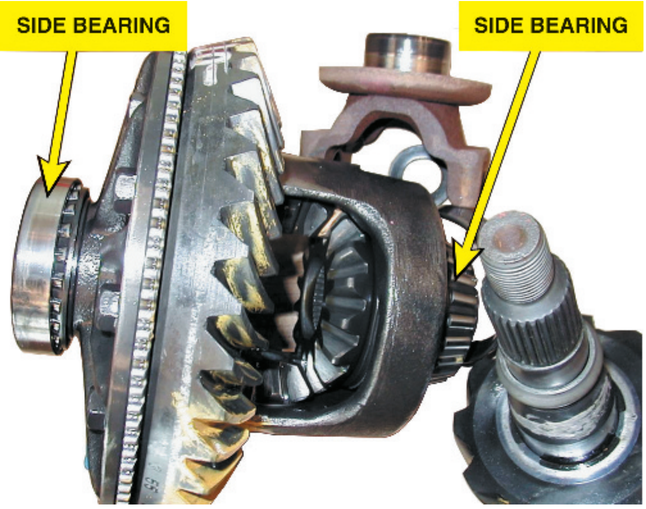

FIGURE 125–16 Side bearings are press fit on the differential case.

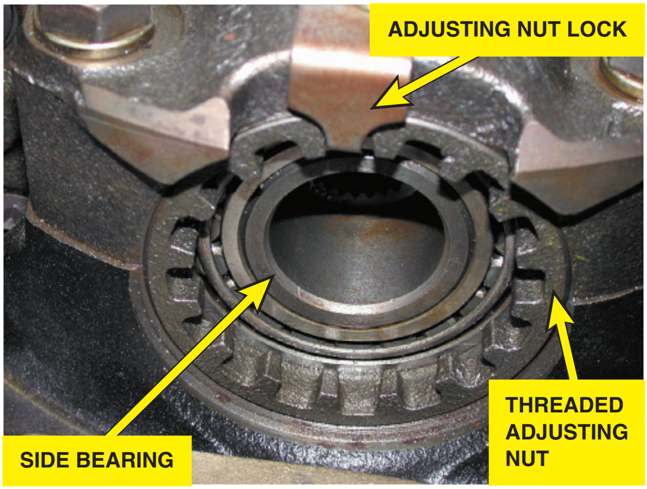

FIGURE 125–17 Some side bearings use threaded adjusters to adjust preload.

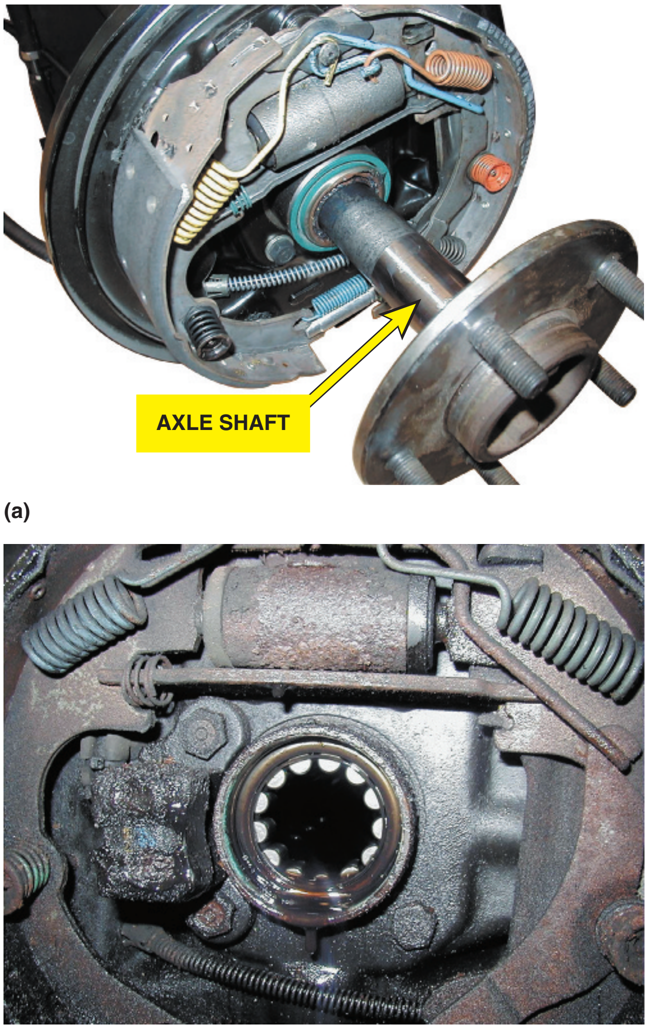
gear-to-pinion backlash (tooth clearance between one gear and the other). This is necessary to ensure enough space between the teeth of the two gears to allow for expansion of the gear tooth dimensions as the unit warms up to operating temperature. When the unit is warm, there must be just enough space between the gear teeth to allow adequate lubrication of the tooth surfaces and still allow full tooth contact for good transfer of torque from one gear to the other. Too much clearance between the gears will allow one to travel too far before contacting the other when the powertrain goes from drive to coast and back again. Excess clearance can result in final drive noise and gear tooth damage.

REAL AXLE BEARINGS

BALL BEARINGS/REAR AXLES If ball bearings are used, the bearing itself absorbs the radial forces. The bearing is placed on the axle and retained by a pressed-on collar. A stamped steel plate bolts to the axle housing and keeps the axle in place. The bearing is prelubricated when it is manufactured. An oil seal is located on the inboard side of the bearing retainer collar, and keeps the hypoid lubricant from reaching the bearing or the brake assembly. In this design, there is no axle shaft end play (thrust) adjustment.

STRAIGHT ROLLER BEARINGS/REAR AXLES If a straight roller bearing is used, the axle surface serves as the inner race. ● **SEE FIGURE 125–18**. The outer race is pressed into the housing, and a grease seal is pressed in afterward. The bearing is lubricated by the hypoid lubricant. This design uses a C-washer



(a)

(b)

FIGURE 125–18 (a) The axle shaft itself is the inner race if a straight roller bearing is used. (b) The straight roller bearings are lubricated by the rear axle fluid, and a leak at the rear axle seal can cause this fluid to get onto brake components.

on the inboard end of the axle, which prevents the axle from moving outward. Outward thrust forces are taken by the C-washer through the axle's side gear and thrust washer, to the differential case and side bearing. Inward thrust forces are taken by the axle shaft inner end pushing on the spider pinion shaft, and passed on to the differential case and the opposite side bearing. There is no axle shaft end play adjustment with this design.

TAPERED ROLLER BEARINGS/REAR AXLES If a tapered roller bearing is used, axle shaft end play is adjustable. The bearing is pre-lubricated before it is installed and is held by a press fit on the axle shaft. A retaining ring is then pressed on the shaft next to the bearing to secure it in place. The axle is prevented from moving outward by a stamped steel retainer plate that bolts to the axle housing. The inner diameter of the plate is threaded to accept a bearing-adjusting nut, which is similar in appearance and function to a differential side bearing adjuster. A variation of this design has the end play adjustment made by shims between the axle housing and the brake backing plate. Thrust is taken from the inner end of the axle by a thrust block mounted on the spider pinion shaft, and passed on to the opposite axle, through its length to the opposite wheel bearing.

DRIVE AXLE IDENTIFICATION

Before any service work is performed on a drive axle assembly, the *exact* axle specification must be determined. Vehicle manufacturers often use axles from more than one axle manufacturer, and each manufacturer has its own individual ratios, parts, service procedures, and specifications. Differential assembly identification includes

- **Visual identification**—usually identifies the manufacturer and size only
- **Axle assembly number**—usually stamped in the axle tube of the differential assembly and identifies the gear ratio and other information
- **Limited-slip identification tag**—often the only external identification whether or not the axle assembly is an open design or limited-slip design
- **Differential cover shape**—and number of bolts used to retain the cover

TECH TIP

Don't Spin Those Wheels!

While driving on ice or snow-covered roads, it is common to see drivers moving slowly up a hill by simply spinning one drive wheel. However, when one wheel is spinning and the other wheel is stationary (or close to stationary), the pinion gears are spinning twice as fast as the drive wheel. This spinning of the drive wheel has been known to completely wear down the pinion gear thrust washers in less than one minute! ● **SEE FIGURE 125–19**. The same wear can occur if different-size tires are used on the same drive axle. Therefore, to prevent expensive repairs, avoid unnecessary tire spinning and check that both tires on the same axle are the same size, brand name, and condition.

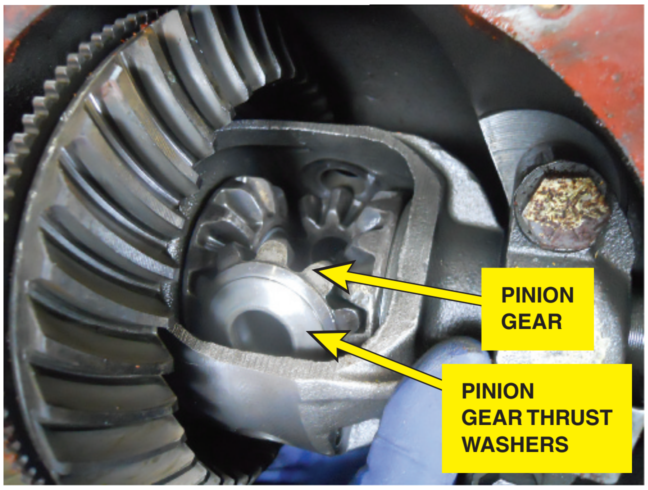


FIGURE 125–19 The pinion gear thrust washers can be destroyed by spinning one wheel for an extended period of time.

DETERMINING THE AXLE RATIO

To determine the axle ratio of a differential without having to remove the axle housing cover, simply follow these steps:

STEP 1 Hoist the vehicle safely.

STEP 2 Mark the rear tires with masking tape at 12 o'clock position.

STEP 3 Mark the driveshaft with masking tape.

STEP 4 Have an assistant hold one drive tire to keep it from moving and slowly rotate the other drive tire exactly 10 times while the assistant counts the driveshaft revolutions.

STEP 5 Multiply the driveshaft revolutions by 2 (except for a limited-slip differential), and then move the decimal point one place to the left. For example, if 10 turns of the tire result in 18.5 turns of the driveshaft, that multiplied by 2 equals 37.0; then, moving the decimal point to the left one place equals a 3.70:1 gear ratio.

TECH TIP

A Quick-and-Easy Backlash Test

Excessive clearance (lash) between the drive pinion and the ring gear can cause driveline clash noise during a gear selector change. To check if the cause is due to the differential, simply hoist the vehicle and, while one wheel and the driveshaft are being held stationary, use your hand to move the opposite wheel. The maximum amount the tire should move is 1 inch (2.5 cm) measured at the tread of the tire. If backlash is greater than this, then further inspection of the differential assembly is required. Beside excessive clearance between the drive pinion and the ring gear, the wear may also be between the pinion and the side gears.

REAR-END NOISE DIAGNOSIS

One of the major reasons why differentials are serviced is to correct a noise problem. Knowing when and under what conditions the noise is noticeable is a big help in identifying which bearing or component is the likely cause. Typical noise and its sources include

- **Grinding or growling noise while turning**—usual cause is a defective axle bearing.
- **Whine noise during cruise**—drive pinion bearings are the likely causes of this type of noise.

DRIVE AXLE INSPECTION

Carefully inspect the drive axle for obvious damage or wear. ● **SEE FIGURE 125–20**. Check the backlash. The backlash is the amount of clearance between the drive pinion and the ring gear; excessive backlash could indicate excessive wear. Use a dial indicator as shown in ● **FIGURE 125–21** to check and compare the results with specifications.

Also use a dial indicator to check **ring gear runout** (● **SEE FIGURE 125–22**). If any of the visual measurement tests indicate a problem or a noise analysis indicates a bearing problem, the axle assembly should be disassembled for further analysis and service.

TOOTH CONTACT PATTERN TEST

A tooth contact pattern test is an excellent method for checking proper drive pinion depth as well as proper backlash between the drive pinion and the ring gear. Any faults in these areas will be reflected in the pattern. The pattern test involves the following steps:

STEP 1 Clean the gear teeth of the ring gear and the drive pinion.

STEP 2 Using a small brush, apply a light coating of iron oxide compound.

STEP 3 Use a small pry bar to apply a load to the ring gear to achieve a more accurate contact pattern. ● **SEE FIGURE 125–23**.

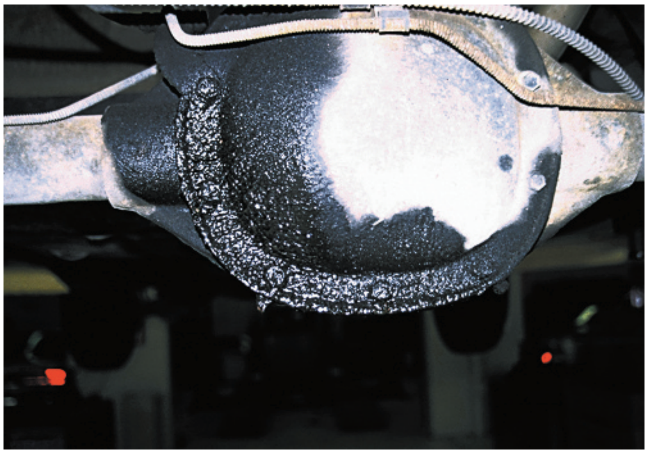

FIGURE 125–20 This differential has obviously been leaking. If the differential lubricant is low, wear may have occurred that would require further inspection.

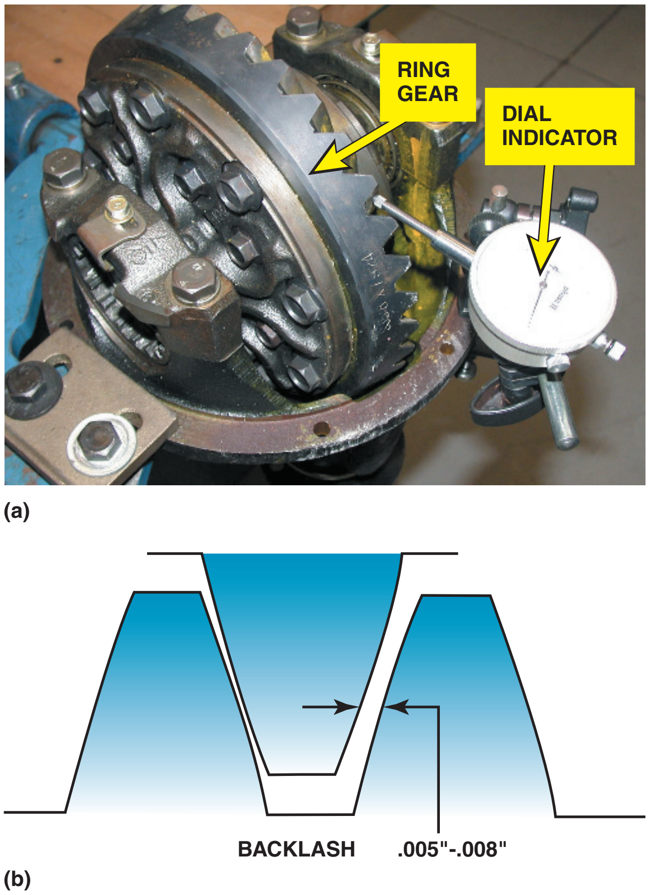

FIGURE 125–21 (a) Backlash is determined by mounting a dial indicator to the differential housing and placing the button of the gauge against a tooth of the ring gear. Moving the ring gear back and forth will indicate on the dial indicator the amount of backlash. (b) Backlash is the clearance between the drive pinion and the ring gear teeth.

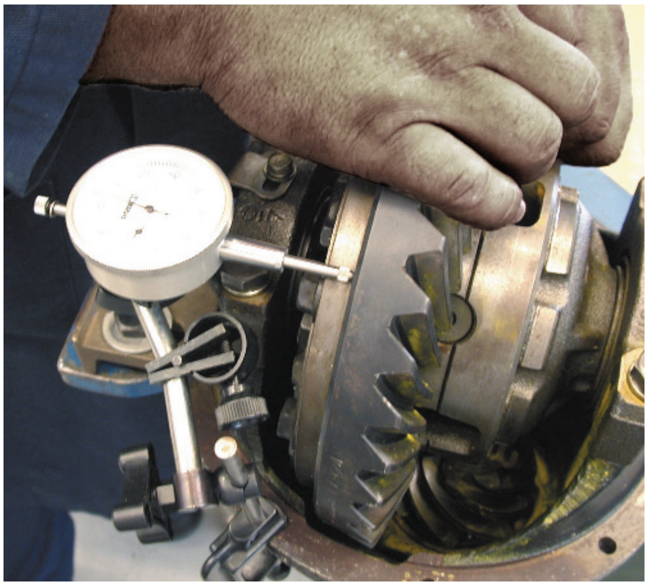

FIGURE 125–22 Ring gear runout should be less than 0.002 inch (0.05 mm) as measured by a dial indicator.

STEP 4 Rotate the drive pinion until the ring gear turns one revolution (about three revolutions of the drive pinion gear).

STEP 5 Repeat rotating the drive pinion in the opposite direction. This will create a contact pattern on both the drive side and the coast side of the ring gear.

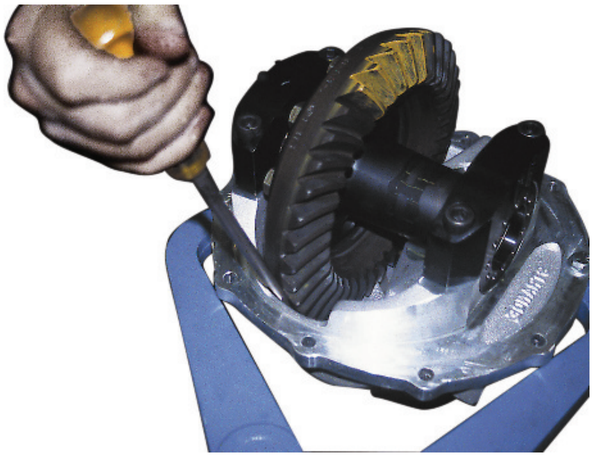

FIGURE 125–23 Force has to be applied to the ring gear to achieve a proper contact pattern.

NOTE: The drive side is the convex surface of the ring gear teeth. The coast side is the concave side of the ring gear. This is true except for many differentials used on the front of four-wheel-drive vehicles. In this case, the drive side in the front differential is the concave surface and the coast side is the convex surface of the ring gear teeth. Always check the service information for the vehicle being serviced for the correct interpretation of the pattern results.

● **SEE FIGURE 125–24** for good and bad tooth contact patterns and what could have caused them.

DRIVE AXLE DISASSEMBLY

Start the disassembly by removing the axle housing cover. Be sure that the old rear-end lubricant is drained into a disposal container according to local, state, provincial, and federal laws and regulations. After the cover has been removed, complete the disassembly by following these steps:

STEP 1 After the cover has been removed, remove pinion shaft lock bolt.

STEP 2 Remove pinion shaft.

STEP 3 Remove two spider gears and two axle side gears.

STEP 4 Push axles in and remove C-clips.

STEP 5 Remove axles.

STEP 6 Mark and remove case caps.

STEP 7 Using a case spreader or two pry bars, pry up and remove carrier case keeping the shims separate. ● **SEE FIGURE 125–25**.

STEP 8 Remove pinion shaft nut and washer. Discard the nut.

STEP 9 Mark and remove companion flange with suitable puller.

STEP 10 Remove front pinion seal and front pinion bearing.

STEP 11 Using suitable punch, drive pinion gear rearward until it is free of housing.

STEP 12 Remove crush collar (never re-use). ● **SEE FIGURE 125–26**.

CAUTION: Do not use an air impact wrench to remove or install the drive pinion nut. The hammer action of the impact wrench can cause the roller bearings to be pounded into the race. This denting of the race is called *brinelling* and can cause premature bearing failure.

PINION SHAFT BEARING REPLACEMENT

The pinion shaft usually has two tapered roller bearings; the small diameter of each bearing faces the other. This arrangement allows the two bearings to absorb thrust load in both directions. When tapered roller bearings are used in a differential, it is very important that they have the proper preload. If a tapered roller bearing is too loose (too little preload), then the bearing cannot properly support and position the pinion shaft. If the preload is too great, excessive heat will quickly destroy the bearing as it expands with heat during normal operation of the rear axle assembly. Two methods are used to ensure proper drive pinion gear preload (● **SEE FIGURE 125–27**):

- Preload shims
- Collapsible spacer

The rear pinion shaft bearing (closest to the drive pinion gear) is usually pressed out the drive pinion. A shim is usually located between the drive pinion gear and the rear drive pinion bearing to properly position the drive pinion in relation to the ring gear. The ring gear and pinion are manufactured as a matched pair and must be installed correctly to be assured of quiet operation and long service life. ● **SEE FIGURE 125–28**. The drive pinion bearing must be pressed off using a hydraulic press or a special tool.

DRIVE PINION DEPTH

The drive pinion gear and ring gear are manufactured as a matched set and must be installed as a set. Due to variances in the production of these gears, it is often necessary to vary the thickness of a shim (thin metal spacer) between the rear pinion bearing and the pinion gear to provide the correct contact tooth pattern when the gears are assembled. Correct drive pinion depth measurement can be determined in several different ways:

- **Wear pattern analysis.** This method is useful as a first step and a last step to verify correct setup (discussed earlier in the chapter). It is time consuming to use this method to determine the thickness of the drive pinion shim because the rear pinion bearing must be pressed off and then back on for each shim change.
- **Plus (+) and minus (–) markings on the drive pinion.** The end of the pinion gear is usually marked as to the variance needed to create the proper ring gear-to-drive pinion pattern:
  A plus (+) sign means the gear is too long and removing a shim(s) is required when assembling the drive pinion into the axle housing.
  A minus (–) sign means that the gear is too short and a shim(s) will be needed when assembling the drive pinion into the axle housing.
- **A gauging set and depth micrometer.** This is a common method used to determine the correct shim thickness necessary to provide the proper gear pattern. ● **SEE FIGURE 125–29**.

PINION GEAR PRELOAD

After the proper drive pinion depth has been determined, the correct size shim is installed and the rear drive pinion bearing is pressed onto the drive pinion. The outer races of the pinion bearing should be replaced in the axle housing and the pinion shaft placed in the housing. It is then necessary to apply the specified preload to the pinion bearings. A new drive pinion nut should be used and tightened to specifications. After the nut has been tightened, torque needed to rotate the drive pinion should be measured using a beam-type torque wrench. The drive pinion nut is then tightened farther until the **turning torque** is within specifications. ● **SEE FIGURE 125–30**.

CHECKING AND CORRECTING BACKLASH

If the ring gear and pinion are being replaced, the bolts that hold the ring gear to the differential case *must* be replaced. ● **SEE FIGURE 125–31**. The differential case with the ring gear is then placed into the differential housing. Backlash is the clearance between the drive pinion gear and the ring gear. A dial indicator is used to measure backlash, as shown in ● **FIGURE 125–32**. The backlash should be checked at three or four points around the ring gear and the lash should not vary over 0.002 inch (0.05 mm). Backlash normally is between 0.005 and 0.008 inch (0.10 and 0.20 mm) for most axle assemblies. Always check the specifications for the differential being serviced. ● **SEE FIGURE 125–33**.

Backlash is corrected by moving the ring gear either closer or farther away from the drive pinion gear. The correction is made

TECH TIP

"Click-Click" Is Okay-"Clunk-Clunk" Is Not

An experienced service technician was observed checking the backlash on a differential. The technician was simply turning the drive pinion by grasping the pinion flange and using wrist action to quickly rotate it first in one direction and then the other. The technician explained that if it made a "click-click" sound, the backlash was usually between 0.005 and 0.008 inch, which is usually within specifications for most differentials. If, however, the sound made was more like a "clunk-clunk," then the backlash was greater than 0.010 inch and had to be corrected. To summarize what the sounds mean when the drive pinion is moved back and forth:

- **No sound when moved back and forth**—too little or no backlash; backlash must be adjusted.
- **A "click-click" sound**—backlash is usually within specifications; double-check with a dial indicator and compare against specifications for the axle being serviced.
- **A "clunk-clunk" sound**—usually too much backlash; correction is required to restore proper backlash.

by either of two methods depending on the manufacturer and the type of differential:

- Transferring shims from one side of the axle housing to the other
- Turning threaded adjusters located in the differential housing bores, as shown in ● **FIGURE 125–34**.

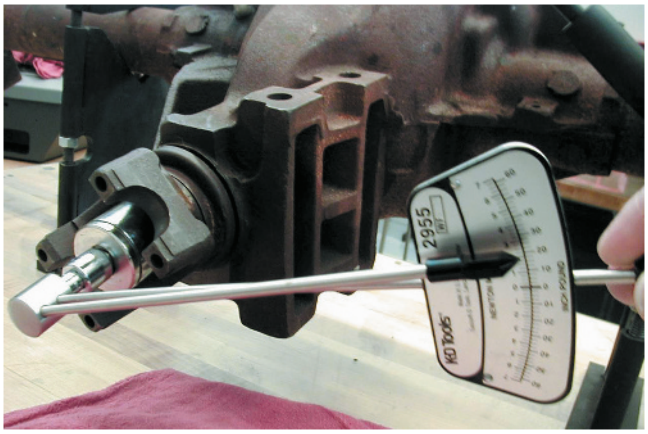

FIGURE 125–30 Using an inch-pound torque wrench to check the rotating torque of the drive pinion. This procedure is very important if the axle uses a collapsible spacer. The drive pinion nut should be gradually tightened and the rotating torque checked to prevent overtightening the nut. If the rotating torque is higher than specifications, the collapsible spacer will require replacement and the installation procedure must be repeated.

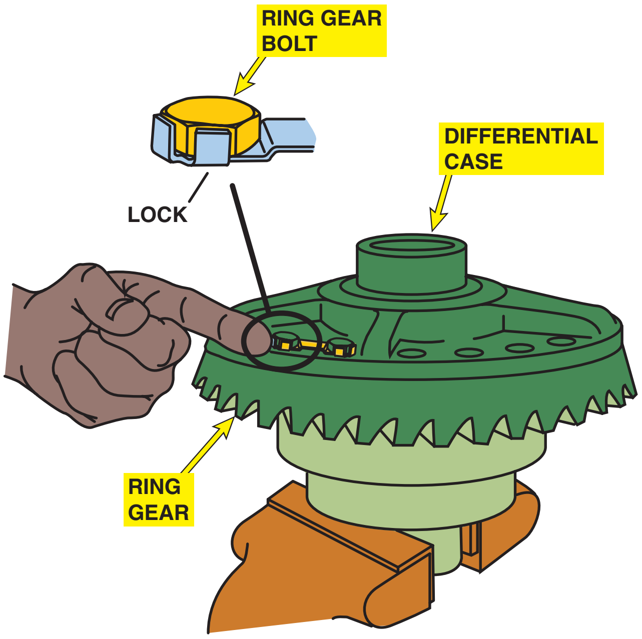

FIGURE 125–31 If the ring gear has been removed from the differential case or if a new ring gear is being installed, always replace the ring gear bolts.

SETTING SIDE BEARING PRELOAD

After the correct backlash has been determined, the side bearing must be correctly preloaded. To accomplish the proper preload, thicker shims than were used to set proper backlash are placed between the housing and the differential to provide for the proper preload on the side bearings. ● **SEE FIGURE 125–35**. Always follow the procedures specified for the axle being serviced. A typical axle may require the installation of a shim 0.004 thicker on both sides. After setting the preload, double-check that the backlash is within specification.

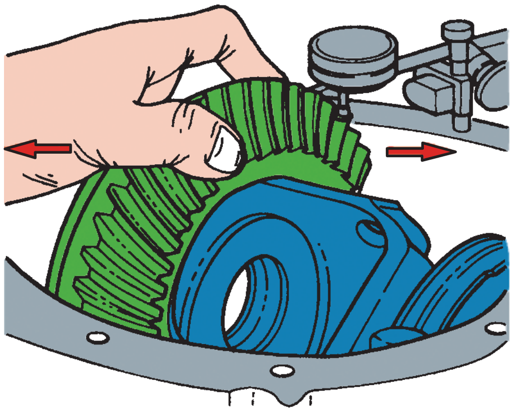

FIGURE 125–32 Backlash should be between 0.005 and 0.008 inch on most differentials. If the backlash is too great, add shim thickness to the ring gear side and subtract shim thickness from the opposite side.

FREQUENTLY ASKED QUESTION

What Is a Spool Rear End?

A spool is a solid piece of metal that takes the place of the side gears and pinion gears in a differential assembly (● **SEE FIGURE 125–36**). A spool used in drag racing is not suitable for street driving because the spool does not allow for any differences in the speeds of the drive wheel during cornering. Obviously, drag vehicles do not turn corners while racing and the spool rear end is one of the reasons they bounce when turning around at the end of the strip to return to the pits.

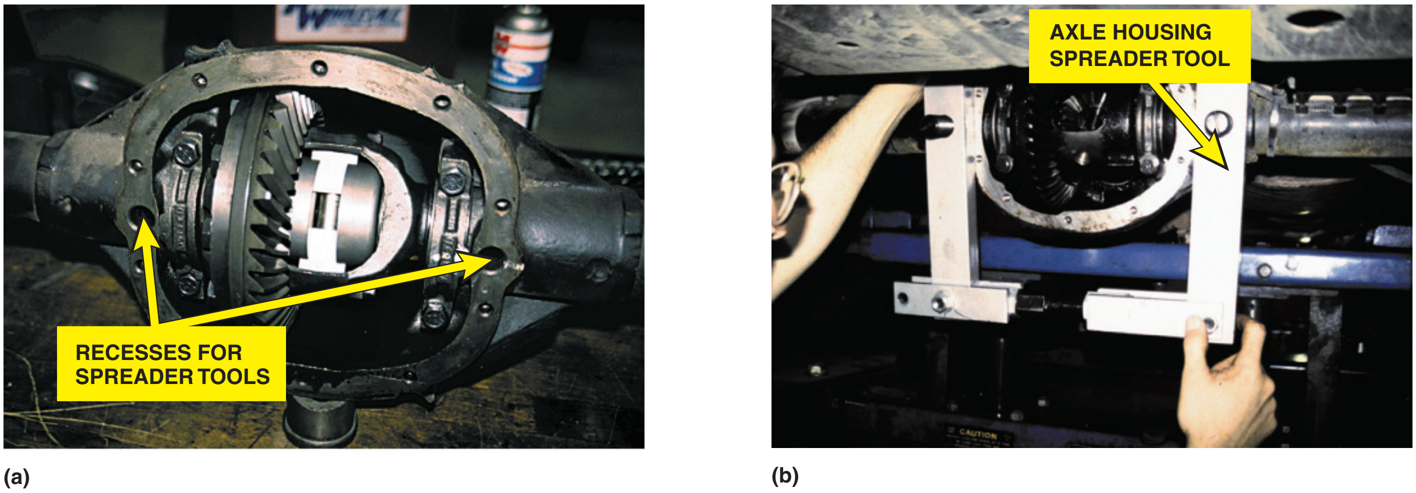

FIGURE 125–33 (a) Some vehicle manufacturers recommend using a housing spreader tool that fits into the round openings on both sides. (b) The spreader tool being installed. The housing is spread a specified amount and the differential is then installed into the housing.

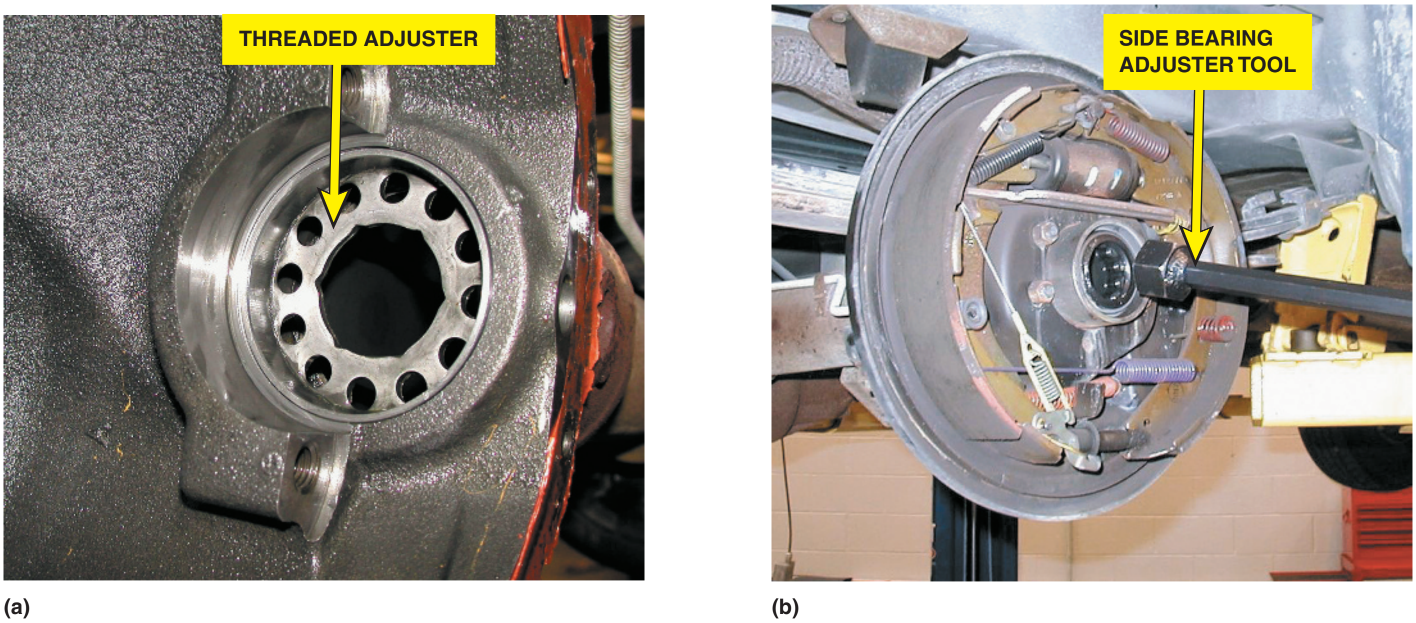

FIGURE 125–34 (a) Note the hex shape of the threaded adjuster used to adjust side bearing preload and ring gear backlash on a Dodge Dakota truck. (b) A long-handled adjuster tool is needed to turn the side bearing adjuster on this truck.

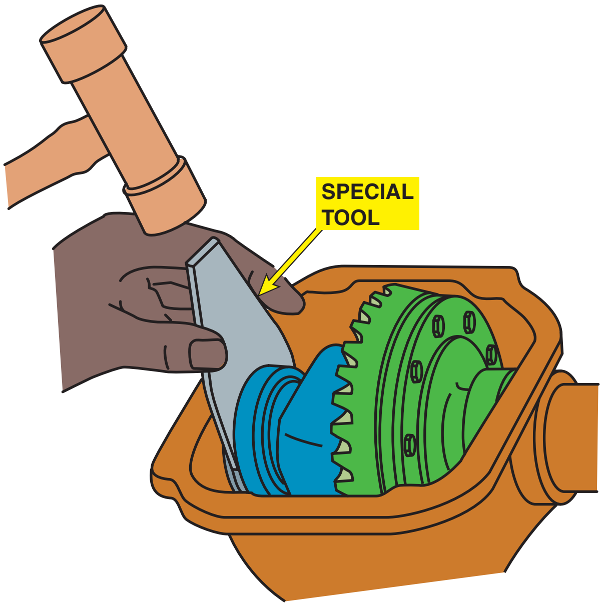

FIGURE 125–35 On many axles, it is necessary to use a special tool to install steel spacers (shims) to achieve the specified backlash and side bearing preload.

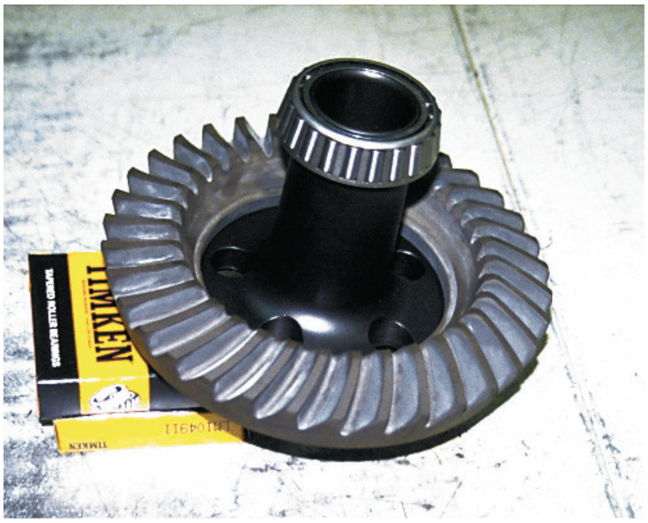

FIGURE 125–36 A spool used in a rear end for drag racing only.

REASSEMBLY OF THE DRIVE AXLE

After the backlash has been checked to be within factory specifications, the axle shafts can be installed. ● **SEE FIGURE 125–37.** Install the retaining "C" clip or bolt the retainer to the axle housing. Clean and install the differential cover and fill with the specified differential lubrication.

DRIVE AXLE LUBRICANT

Because all differentials use hypoid gear sets, a special lubricant is necessary because the gears both roll and slide between their meshed teeth. Gear lubes (GL) are specified by the American Petroleum Institute (API):

GL-1 Straight mineral oil

GL-2 Worm gear lubricant

GL-3 Mild EP lubricant (will *not* protect hypoid gears)

GL-4 Mild EP lubricant suitable for manual transmissions/ transaxles

GL-5 EP lubricant okay for hypoid gears (meets military Mil-L2150B requirements)

● **SEE FIGURE 125–38.**

NOTE: EP additives contain sulfurized esters and organic sulfur phosphorous compounds. These ingredients give the lubricant a very strong pungent smell. To avoid possible skin irritation, always wear protective gloves or wash your hands thoroughly with soap and water if exposed to differential lubricant.

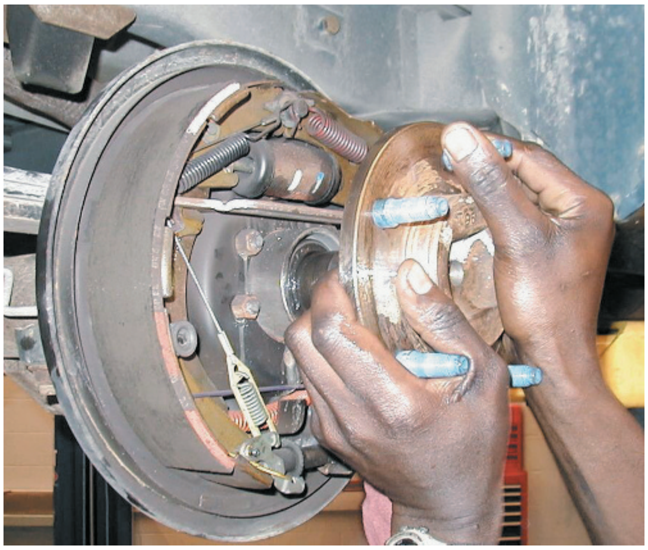

FIGURE 125–37 Install the axle shaft, being careful to not damage the seal.

FREQUENTLY ASKED QUESTION

What Do I Do about Drive Pinion Bearing Preload When I Replace Just the Pinion Seal?

To replace a pinion seal, the drive pinion nut and pinion flange must be removed.

CAUTION: Do not use an air impact wrench on the drive pinion nut. The pinion bearings can be damaged by the impact of the wrench.

Before the nut is removed, make a mark on the pinion nut and on the axle housing. After the new pinion seal is installed, tighten the pinion nut to the same position it was in before disassembly and then rotate the nut 1/16 inch (1.5 mm) farther. This extra rotation makes sure that the collapsible space (crush sleeve) is still able to maintain the proper preload on the pinion bearing. Another method is to measure the rotating torque of the drive pinion using an inch-pound beam-type torque wrench after removing both rear wheels and brake drums. After installing the replacement pinion shaft seal, tighten the drive pinion nut until the rotating torque is 3 to 5 in-lb more than the reading obtained before the pinion nut was removed.

FIGURE 125–38 A container of GL-5 SAE 80W-90 gear lubricant.

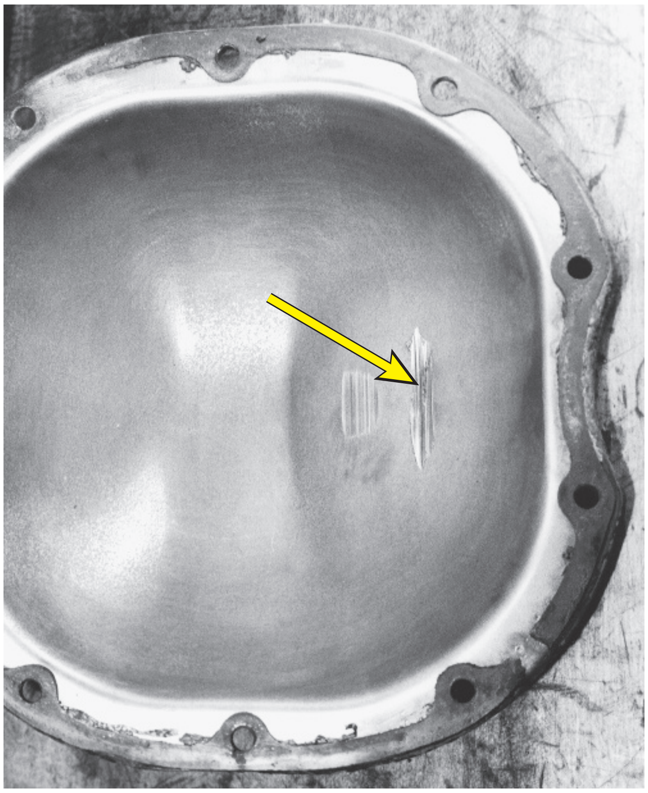

FIGURE 125–39 The beginning automotive student did not realize that the axle housing cover could fit the wrong way. The only problem was that the ring gear scraped against the cover.

CASE STUDY

I Didn't Know It Would Fit the Wrong Way!

An automotive student changed the differential lubricant by removing the housing cover. The cover was reinstalled and then filled with the correct lubricant. However, when the student drove the vehicle it made a grinding sound that was not there before the differential service. When the cover was removed, it was discovered that the cover had been installed with the raised area on the right side of the housing instead of on the left side and the ring gear had rubbed a groove in the cover, as shown in ● **FIGURE 125–39**. Installing the cover correctly stopped the grinding sound.

Summary:

Complaint—Vehicle made a grinding noise after a differential fluid service procedure was performed.
Cause—The drive axle hosing cover was installed incorrectly.
Correction—The cover was removed and installed correctly.

Most differentials require

1. SAE 80W-90 GL-5
2. SAE 75W-90 GL-5
3. SAE 80W GL-5

NOTE: Always check the *exact* specification before adding or replacing rear axle lubricant.

Limited-slip differentials (often abbreviated LSD) usually use an additive that modifies the friction characteristics of the rear axle lubricant to prevent chattering while cornering.

HINT: If chattering becomes noticeable while cornering, replace the old differential lubricant with the correct lubricant and add limited-slip additives if specified by the vehicle manufacturer. After refilling the differential, drive the vehicle in a figure-eight pattern at least four times to help all of the lubricant and additives get into the clutch plates. This usually stops the chattering-while-cornering problem.

REVIEW QUESTIONS

1. Explain how to determine the axle ratio without removing the housing cover.
2. Describe how to perform a ring gear tooth contact pattern test.
3. List three methods that may be used to determine the proper drive pinion gear depth.
4. Explain how to achieve proper drive pinion gear bearing preload.
5. Describe how to adjust the position of the ring gear to achieve the proper backlash.

a. drive shaft
b. pinion gear
c. differential case
d. spider gears

2. A limited-slip differential has _____________ on the side gears that a standard (open) differential does not have.

a. sliders
b. clutch packs
c. slip teeth
d. slipper rings

3. A collapsible spacer is used in some differentials to provide _____________.

a. a lubrication path to the drive pinion bearing
b. the proper preload for the side bearings
c. the proper preload for the drive pinion bearings
d. the proper amount of slippage in a limited-slip differential

4. The shim used on a drive pinion gear is used to properly position the gear so that it can correctly mesh with the _____________.

a. ring gear
b. side gear
c. differential pinion gears
d. Both b and c

5. Technician A says that the convex side of the ring gear is the drive side on most rear axle assemblies. Technician B says that the convex side of the ring gear is the drive side on differentials used in the front of many four-wheel-drive vehicles. Which technician is correct?

a. Technician A only
b. Technician B only
c. Both Technicians A and B
d. Neither Technician A nor B

6. A growling sound is heard from the rear of a rear-wheel-drive vehicle during cornering only. Technician A says that defective rear axle bearings may be the cause. Technician B says that defective drive pinion bearings may be the cause. Which technician is correct?

a. Technician A only
b. Technician B only
c. Both Technicians A and B
d. Neither Technician A nor B

7. Technician A says that if the backlash is okay, then the side bearing preload is also okay. Technician B says that a ring gear tooth pattern check will indicate if the drive pinion depth is correct. Which technician is correct?

a. Technician A only
b. Technician B only
c. Both Technicians A and B
d. Neither Technician A nor B

8. The backlash exceeds specifications. The technician should position the ring gear _____________.

a. closer to the drive pinion gear
b. farther from the drive pinion gear
c. toward the heel
d. toward the toe

9. The backlash is less than specifications (too low). This will cause the ring gear tooth pattern to be too close to the _____________.

a. heel
b. flank
c. toe
d. face

10. Two technicians are discussing which lubricants are used in a limited-slip differential. Technician A says to use SAE 80W-140. Technician B says that most vehicle manufacturers usually specify SAE 80W-90 be used with or without special limited slip additives. Which technician is correct?

a. Technician A only
b. Technician B only
c. Both Technicians A and B
d. Neither Technician A nor B

FOUR-WHEEL-DRIVE SYSTEMS

PURPOSE AND FUNCTION Two-wheel-drive vehicles use engine torque to turn either the front or the rear wheels. A differential is required to allow the drive wheels to travel different distances and speeds while cornering or driving over bumps or dips in the road. A four-wheel-drive vehicle, therefore, requires two differentials—one for the front wheels and one for the rear wheels.

NOTE: The term 4 × 4 means a four-wheeled vehicle that has engine torque applied to all four wheels (four-wheel drive). A 4 × 2 means a four-wheeled vehicle that has engine torque applied to only two wheels (two-wheel drive).

Full-time four-wheel-drive vehicles require more than just two differentials. The front and the rear wheels of a four-wheel-drive vehicle also travel different distances and speeds whenever cornering or running over dips or rises in the road.

TRANSFER CASE Engine torque from the transmission is applied directly to the rear differential through the transfer case. ● **SEE FIGURE 126–1**.

The transfer case permits the driver to select different modes and ranges of operation.

These positions and their meanings include

- 4H four-wheel drive with no gear reduction in the transfer case.
- 4L four-wheel drive with gear reduction. Use of this position is usually restricted to low speeds on slippery surfaces.
- 2H two-wheel drive (rear wheels only) in high range, meaning no gear reduction in the transfer case.

To prevent driveling binding and stress when in four-wheel-drive, there must be a way to allow for differences in front-to-rear driveline speed variation. Three methods to do this are

METHOD 1—LOCKING HUBS In normal 4H driving on hard surfaces, the front hubs must be in the unlocked position. The front hubs are locked whenever driving on loose road surfaces to absorb and allow for tire slippage due to the different tire speeds front to back. ● **SEE FIGURE 126–2**.

CAUTION: Failure to unlock the front-wheel hubs while driving on a hard road surface can cause serious driveline vibrations and damage to driveshafts, U-joints, and bearings as well as to the transfer case, or transmission,

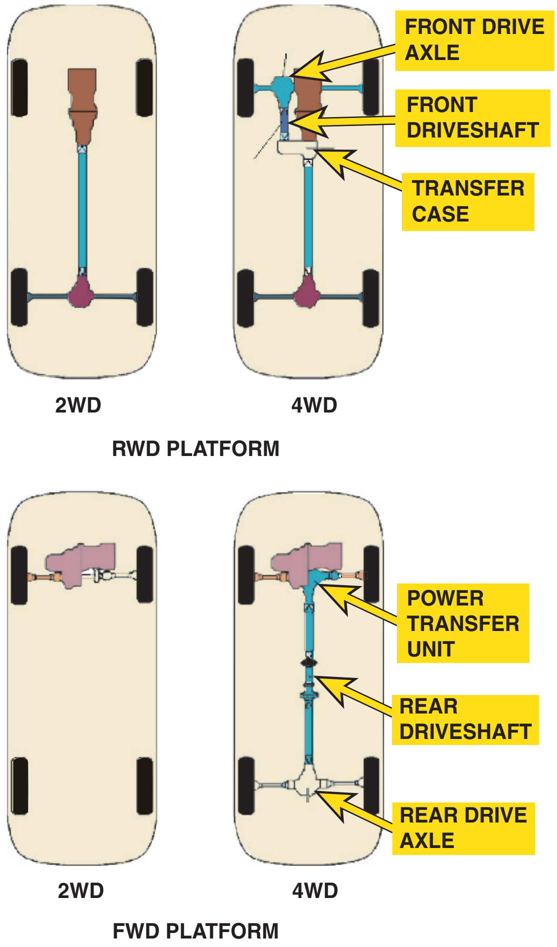

FIGURE 126–1 Four-wheel-drive vehicles can be achieved by using an existing rear-wheel-drive arrangement and adding a transfer case, or a front-wheel-drive arrangement with the addition of rear axle output shaft and center differential assembly.

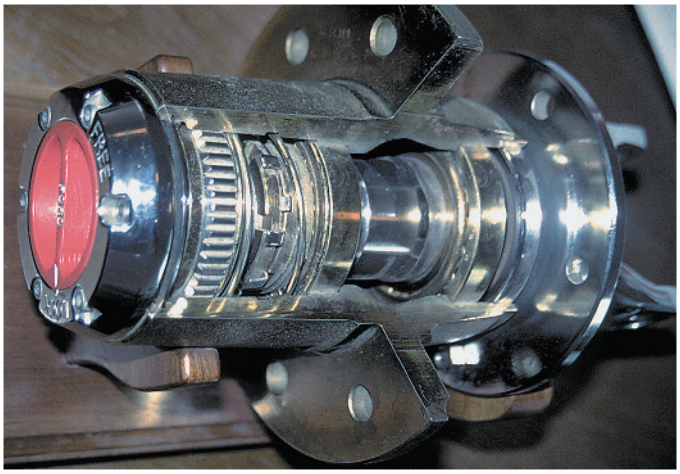

FIGURE 126–2 Cutaway of a manually operated locking hub.

METHOD 2—AUTOLOCKING HUBS Another method of locking the hubs on a part-time four-wheel-drive system is with a clutch arrangement built into the hub assembly. Whenever driving on smooth, hard road surfaces, the hubs "free wheel" and allow the front wheels to rotate at different speeds from the rear wheels. When the speed difference between the wheels and the front drive axle is great, the hubs will automatically lock and allow engine torque to be applied to the front wheels. ● **SEE FIGURE 126–3** shows an autolocking hub with the cover

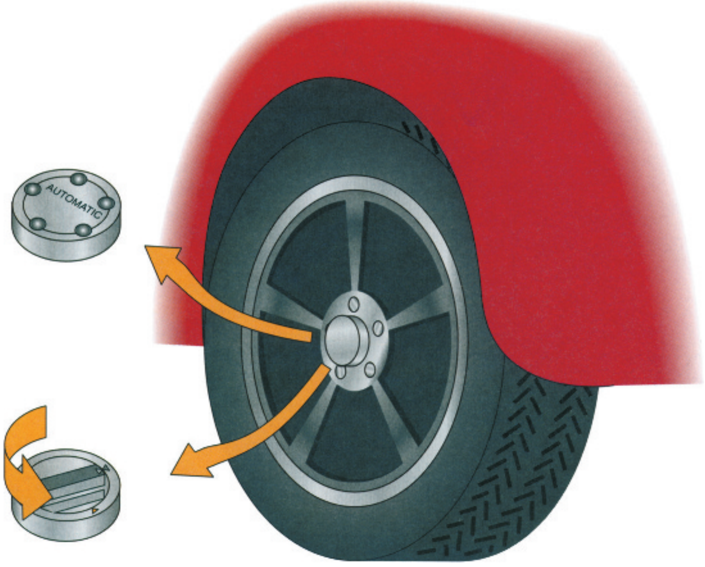

FIGURE 126–3 Manual locking hubs require that the hubs be rotated to the locked position by hand to allow torque to be applied to the front wheels. Automatic locking hubs enable the driver to shift into four-wheel drive from inside the vehicle.

FREQUENTLY ASKED QUESTION

What Is the Difference between Four-Wheel Drive (4WD) and All-Wheel Drive (AWD)?

The major difference between four-wheel drive and all-wheel drive is that four-wheel-drive units contain a transfer case with a low range. Most all-wheel-drive vehicles do not have low range and are in high four-wheel drive all the time. Both use a center (interaxle) differential and both usually use a viscous coupling or an electronically controlled clutch to control (lock) the center differential.

TECH TIP

How to Tow a Four-Wheel-Drive Vehicle without Doing Harm

If any of the drive wheels are on the ground, the wheels are turning the axles. Depending on the exact type of four-wheel-drive vehicle being towed, this rotation of the wheels can cause severe wear; therefore, most experts suggest the following options:

- **Placing the vehicle on a flatbed or trailer.** This keeps all four wheels off the ground and is the safest method for transporting a four-wheel-drive (or all-wheel-drive) vehicle without doing any harm.
- **Hoisting the front wheels off the ground and placing the rear wheels on a dolly.** This procedure also keeps all wheels off the ground and therefore prevents any damage being done to the powertrain as a result of towing. ● **SEE FIGURE 126–4.**

Always check with vehicle-specific information for exact towing procedures.

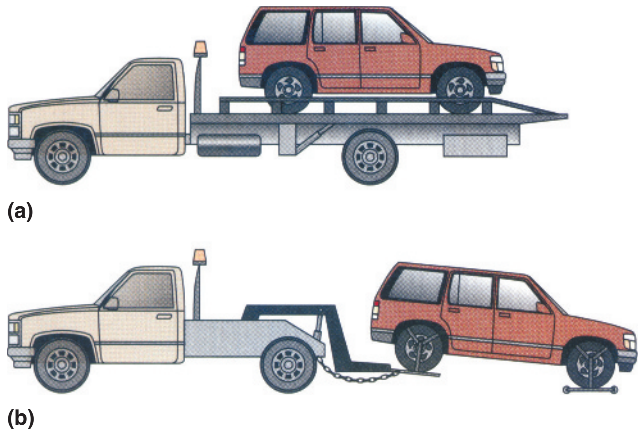

FIGURE 126–4 If a four-wheel-drive vehicle must be towed, it should be either on (a) a flatbed truck or (b) a dolly.

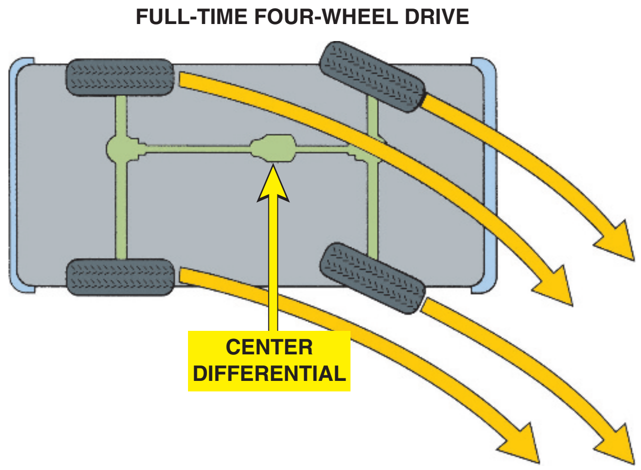

FIGURE 126–5 When turning a corner, each wheel takes a slightly different path and rotates at a slightly different speed. Unlike a part-time four-wheel-drive system, which when engaged locks the front and rear axles together, a full-time system uses a center differential that allows for any speed differences between the front and rear axles. It can therefore be activated on any surface—slippery or dry.

removed. Some automatic-locking hubs are unlocked by disengaging four-wheel drive and driving in reverse for several feet.

METHOD 3—FULL—TIME FOUR-WHEEL DRIVE This method uses a center differential to allow front and rear wheels to travel at different speeds under all operating conditions, as shown in ● **FIGURE 126–5**. Although this drive train design is the easiest to operate both on and off the road, the center differential can cause the vehicle to get stuck in mud or snow even though it is a four-wheel- drive vehicle.

All open-style differentials allow for speed differences and torque is applied equally, so if one wheel is on ice or mud, the other wheel receives the same low torque. This is why many vehicles spin just one wheel when stuck on ice or snow. But if one rear wheel starts to spin, the vehicle may not move forward at all!

There are two methods used to lock the center differential to prevent this from happening.

- A **viscous coupling** is commonly used on many four-wheel-drive vehicles to provide an "automatic" lockup of the center differential. A viscous coupling is a type of fluid clutch. When the speed difference between the front and rear wheels is high enough, the silicone fluid inside the coupling stiffens to reduce the speed difference between the front and rear drive shafts. ● **SEE FIGURES 126–6 AND 126–7**.
- An **electronically controlled clutch assembly** is actuated by the vehicle's computer based on inputs from the ABS wheel speed sensors. If a wheel starts to spin, the computer can pulse the clutch on and off as necessary to control the amount of wheel slippage.

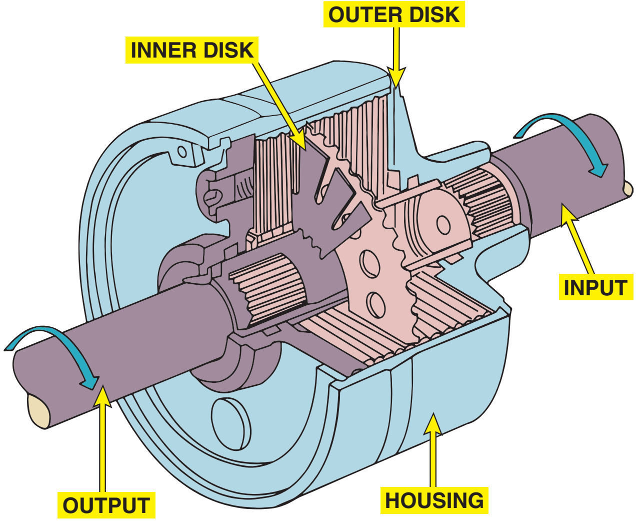

FIGURE 126–6 A viscous coupling is a sealed unit containing many steel discs. One-half of them are splined to the input shaft, with every other disc splined to the output shaft. Surrounding these discs is a thick (viscous) silicone fluid that expands when hot and effectively locks the discs together.

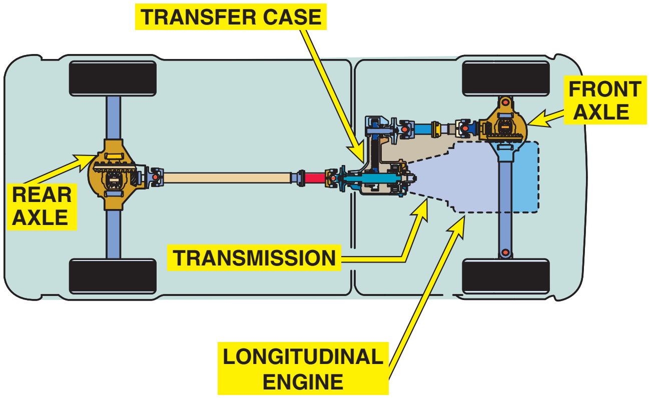

FIGURE 126–7 A typical four-wheel-drive vehicle that uses a longitudinal engine and a transfer case to send engine torque to both the front and rear wheel.

ALL-WHEEL DRIVE

Some cars and light trucks are equipped with an all-wheel-drive system that uses a transfer case with a center differential and only one speed (high). Low-range gear reduction is not used. A viscous coupling is usually incorporated into the center differential to provide superior all-weather traction. Combined with a limited-slip differential in the rear, and sometimes also in the front, an all-wheel-drive system can provide ideal road traction under all driving conditions without any action by the driver. ● **SEE FIGURE 126–8.**

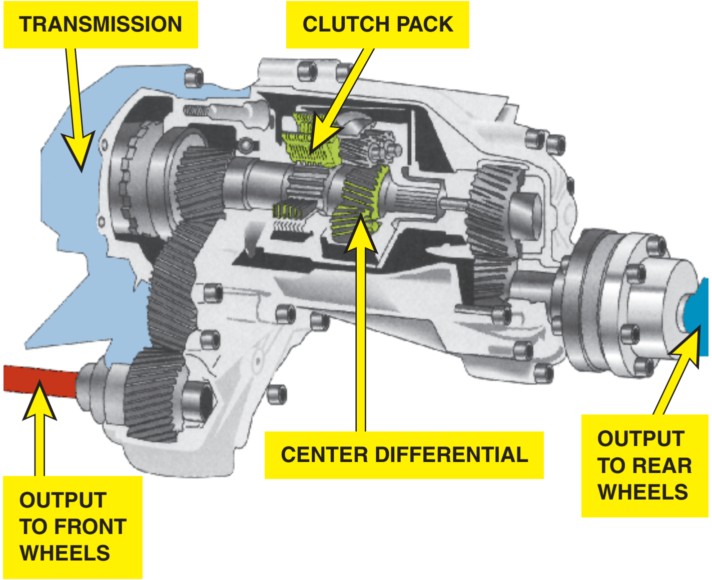

FIGURE 126–8 The center differential is the heart of a typical all-wheel-drive system. All-wheel-drive systems do not use a low range, and therefore the vehicle may not be able to go off-road like a vehicle equipped with a four-wheel drive with a low range.

FREQUENTLY ASKED QUESTION

What Is Brake-Actuated Traction Control?

The engine torque of a full-time four-wheel-drive vehicle (with the center differential unlocked) is split into four nearly equal parts. One quarter of the torque is applied to each wheel. If a brake is applied to a spinning wheel, the torque to that wheel is increased, which will increase the torque to all of the other wheels. The increased torque applied to the wheels that have contact with a surface that has some traction will enable the vehicle to proceed. This is the principle involved in brake-controlled traction control such as is used on the Mercedes M4 sport utility vehicle (SUV).

FRONT AND REAR DIFFERENTIAL AXLE RATIOS

In most four-wheel-drive vehicles, the overall gear ratio of the front differential is slightly higher than the overall ratio of the rear differential. The overall ratio is determined by multiplying the gear ratio by the differential ratio. See the following chart comparing the ratios for the front and rear differentials of a typical four-wheel-drive vehicle equipped with a manual five-speed transmission.

Manual Transmission and Final-Drive Gear Ratios

Speed	Gear Ratio	Final-Drive Ratio	Overall Ratio
1st	3.083:1	4.933 front 4.927 rear	15.208 front 15.190 rear
2nd	1.684:1	4.933 front 4.927 rear	8.307 front 8.297 rear
3rd	1.115:1	4.933 front 4.927 rear	5.500 front 5.494 rear
4th	0.833:1	4.933 front 4.927 rear	4.109 front 4.104 rear
5th	0.666:1	4.933 front 4.927 rear	3.285 front 3.281 rear

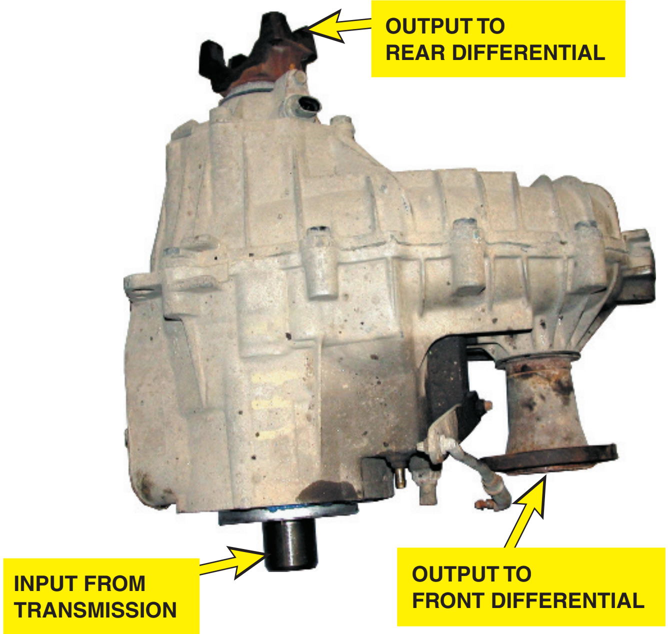

FIGURE 126–9 A typical transfer case is attached to the output of the transmission and directs engine torque to the rear or to the front and rear differentials.

Although the difference between the ratios is small, the purpose is to prevent the drive train from binding. With the front differential ratio being just slightly higher, the tendency is for the front of the vehicle to pull the vehicle, thereby eliminating the problem of having the rear pushing at the exact same ratio as the front is pulling. The different ratios also help reduce resonant vibration and noise created in the driveline.

TRANSFER CASE

The purpose and function of the transfer case is to direct engine torque to the front and rear axle assemblies. ● **SEE FIGURE 126–9.** A four-wheel-drive transfer case is basically an auxiliary 2-speed transmission. It uses the transmission output as an input to a secondary gear train or planetary gear set, which provides a low and high range. The transfer of torque to the front axle output shaft can be accomplished either by a gear-to-gear transfer or a gear and chain transfer. The gear ranges can be engaged a number of ways, such as a manual lever, electrical, or vacuum actuators. A transfer case has one input shaft (connected to the output of the transmission) and two output shafts (● **SEE FIGURE 126–10).** The two output shafts are connected to the driveshafts and transfer torque to the front and rear differentials. Most transfer cases also provide for two types of shifts:

- **Mode shift.** Either two-wheel drive or four-wheel drive may be selected. Many transfer cases also have a neutral position. The mode shift is achieved by the use of a floor-mounted lever to engage and disengage a clutch inside the transfer case. This shift is usually performed when the vehicle is stopped. However, new designs allow the mode shift to be performed under most driving conditions.

NOTE: The mode shift is not available on all-wheel-drive vehicles.

- **Range shift.** A **low range** may be selected to deliver high torque at low speeds to the drive wheels. Low range usually provides a 2:1 to 3:1 gear reduction. High range (usually 1:1) simply transfers engine torque at the same speed as the output shaft of the transmission.

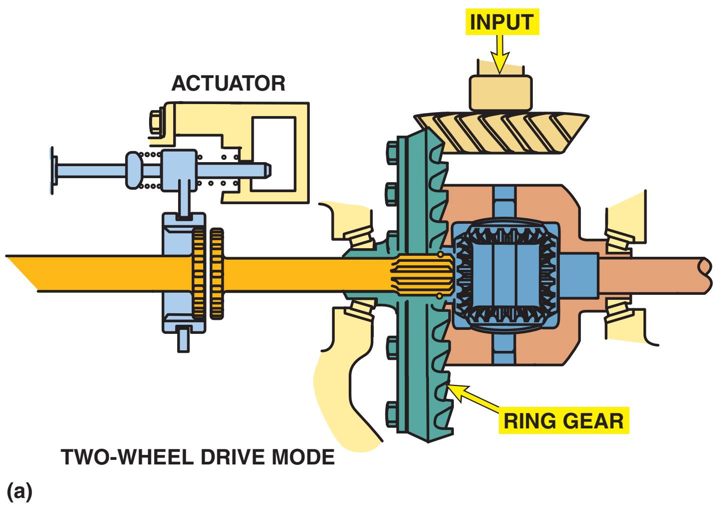

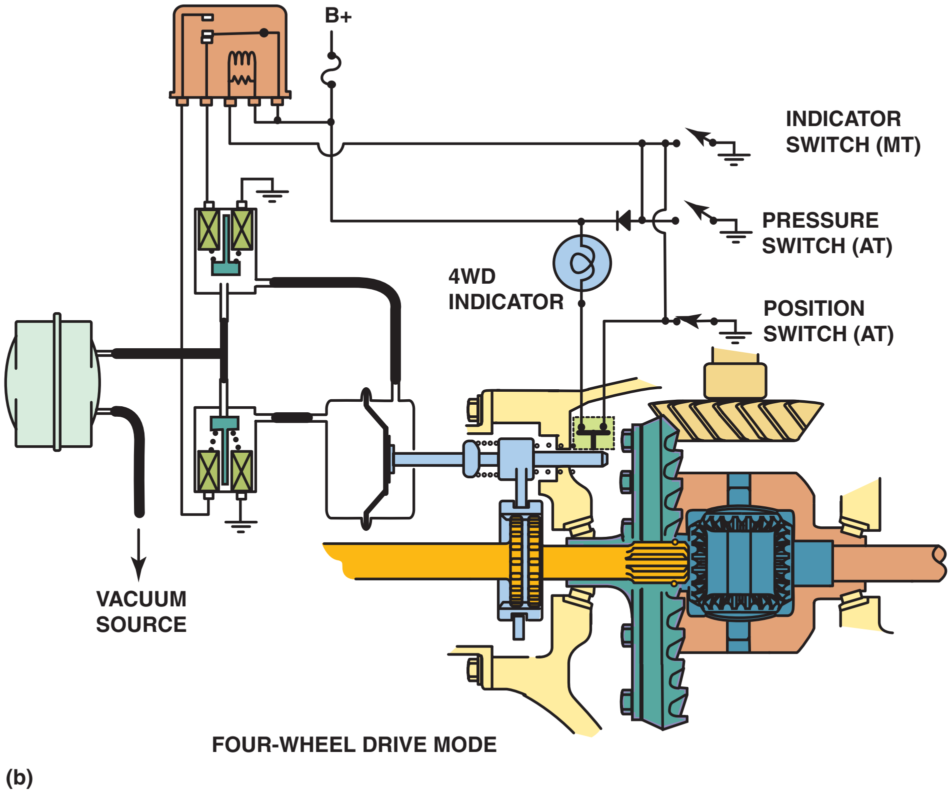

FIGURE 126–11 (a) When one axle shaft is disconnected, both front wheels can rotate independently, reducing excessive tire wear. (b) In four-wheel-drive mode, vacuum is applied to the front part and the opposite side is vented to atmospheric pressure retracting the shift motor stem. The shift fork and collar move into engagement with both axle shaft gears. Engine torque from the front differential can now be applied to both front axles. When the transfer case is placed in two-wheel drive, the vacuum is applied to the other side of the diaphragm and the shift collar moves, unlocking the front axles.

NOTE: Part-time four-wheel drive means that the transfer case does not include a differential.

GEAR-TO-GEAR TRANSFER CASES Gear-to-gear transfer cases are simple in design. Three gear shafts are in mesh within the transfer case. One gear shaft is attached to the transmission output shaft. The second shaft acts as an idler, and the third shaft is the output to the front axle. Gear-to-gear transfer cases, in most cases, have two speeds. The first, 4-wheel-drive low, is a gear reduction that is usually around two to one (2:1). The second gear in the transfer case is a direct drive. The gears are engaged by sliding collars or synchronizers to lock the gears to the shaft. Neutral is accomplished when neither gear collar is locking a gear in place.

TWO-WHEEL-DRIVE OPERATION When the transfer case controls are in two-wheel drive, the front differential assembly is disconnected from the transfer case. This disconnection is usually accomplished by disconnecting one of the drive axles, as shown in ● **FIGURES 126–11 AND 126–12.** The disconnect mechanism in the front axle and a synchronizer assembly in the transfer case combine to remove torque for the front wheels.

FOUR-WHEEL-DRIVE OPERATION To achieve four-wheel drive, two things must occur:

- A synchronizer assembly connects the torque from the engine to the front driveshaft in the transfer case.
- The drive axles must be connected to allow the torque from the front differential to be applied to the drive wheels.

PLANETARY GEAR SET TRANSFER CASES Many transfer cases use a planetary gear set for gear reduction in low range. A planetary gear set includes the following three elements:

1. **Sun gear.** This gear is in the center like the position of the sun is in our solar system.
2. **Planet pinions.** The planet pinion gears rotate around the sun gear, like the planets around the sun, and are attached by a **planet carrier**.

RING GEAR (ANNULUS OR INTERNAL GEAR)
SUN GEAR
PLANET CARRIER
PLANET PINION (3)

FIGURE 126–13 A typical planetary gear set used in a transfer case.

3. **Ring gear.** The outer ring gear has teeth on the inside that mesh with the teeth of the planet pinion gears. The ring gear is also called the **annulus gear** or **internal gear** because the gear teeth are on the inside (rather than the outside) portion of the gear.

The gear teeth of a planetary gear set remain in constant mesh. When gear reduction is needed, the sun gear is often the drive gear and the planet carrier is often the driven gear. The gear ratio reduction depends on the number of teeth on the various gears used in a planetary gear set. ● **SEE FIGURES 126–13 AND 126–14.** To achieve direct 1:1 output from the transfer case, any two of the three elements can be locked together and the entire assembly will rotate as a unit.

Power flows through a planetary gear set in several steps to get from the drive action of the first member to the driven action of the last member. The terms "drive" and "driven" simply describe how any two gears work together. When three or more gears are involved, the second gear is a *driven* gear in relation to the first, but a *drive* gear in relation to the third. For this reason, the drive member of a planetary gear set is called the **input member**, the held member, the **reaction member**, and the driven member, the **output member**. ● **SEE FIGURES 126–15 THROUGH 126–17.**

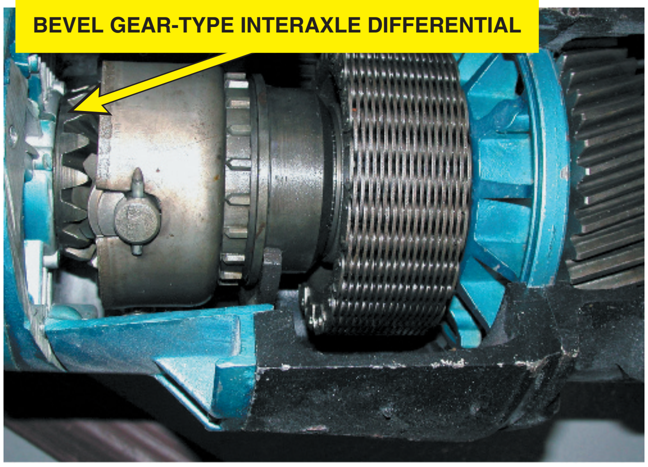
INTERAXLE DIFFERENTIAL

All-the-time four-wheel-drive, all-wheel-drive, and full-time four-wheel-drive systems use an **interaxle differential (center differential)** to prevent driveline harshness and vibration, commonly referred to as driveline windup. An interaxle differential can be found in various configurations including

- Standard bevel gear differential
- Planetary gear differential
- Viscous coupling

Although they are different in appearance, interaxle differentials serve the same purpose, to maintain smooth operation while making turns in a four-wheel-drive/all-wheel-drive vehicle. The **bevel gear differential** uses two bevel gears or spider gears attached to the output shaft of the transmission. Two to four differential pinion gears are attached to a carrier, which is attached to the transfer gears. In other words, it operates in the same fashion as the differential in a rear axle; power is transferred to the tire with the least traction. When there is unequal traction between the front and rear axles, the axle with the most traction is allowed to slip enough to prevent damage to driveline components. ● **SEE FIGURE 126–18.**

With this setup, the loss of traction at one wheel could effectively disable the vehicle. For example, if one wheel had zero traction, the majority of engine torque would be applied to that wheel. In a standard bevel gear setup, torque is split between the front and rear axles. If there is a loss of traction in the front, the transfer of torque to the rear axle will be significantly lowered. To remedy this condition, auto manufacturers incorporate an internal clutch mechanism, much like a limited-slip unit, to increase torque transfer and still lessen driveline vibration and harshness.



BEVEL GEAR-TYPE INTERAXLE DIFFERENTIAL

FIGURE 126–18 A bevel gear-type interaxle differential.

A planetary gear set is often incorporated in transfer cases to act as a differential.

A viscous coupling is nothing more than a selection of steel plates housed in a sealed steel drum. ● **SEE FIGURE 126–19.** The viscous coupling is not active during equal traction conditions.

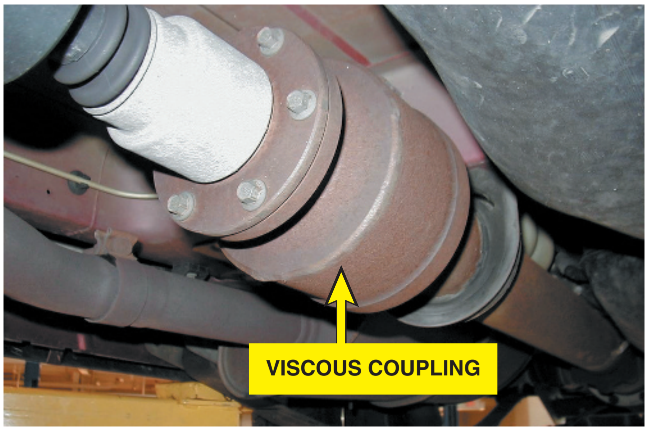


FIGURE 126–19 A viscous coupling. Note that the unit is attached to the output shaft between the transfer case (or transaxle) and the rear differential. A typical viscous coupling in a sealed unit is serviced as a complete assembly.

The viscous coupling does actively transfer torque during light to moderate cornering, but there is a certain amount of slippage under these conditions to prevent driveline windup. If there is a significant loss of traction, the speed differences between the front and rear axles increase, and this increase in plate speed heats the silicon fluid in the viscous coupling, causing it to thicken to the point that it transfers more torque to the axle that is losing traction. During a severe loss of traction, the viscous fluid thickens enough to lock the plates together, dividing engine torque equally 50/50 between the front and rear axles.

FOUR-WHEEL-DRIVE AXLES

Four-wheel-drive vehicles use a variety of driveshafts and U-joint designs:

- **Standard Cardan-type U-joints.** ● **SEE FIGURE 126–20.** If this type of U-joint is used on the front wheels of a four-wheel-drive vehicle, the different speeds it creates can cause the front wheels to skip, hop, and shake if engine torque is applied while on dry pavement and turning a corner at the same time. This is normal for this type of U-joint used on the front wheels of a four-wheel-drive vehicle.

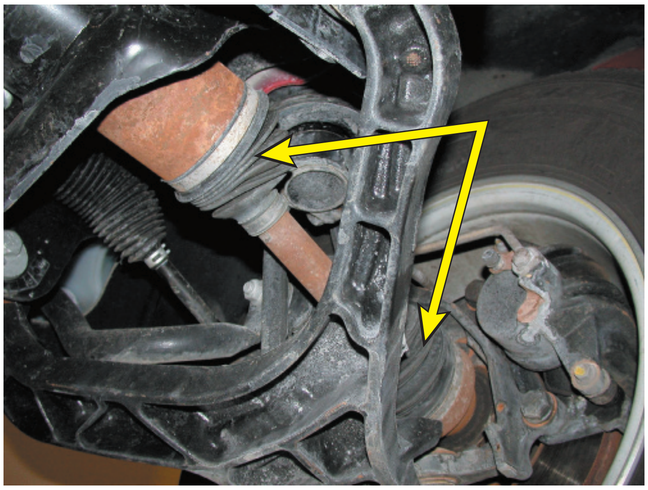

FIGURE 126–21 Constant velocity (CV) joints are used on the front axles of many four-wheel-drive vehicles like this Chevrolet Blazer.

- **Constant velocity (CV) joints.** The use of CV joints at the front wheels allows engine torque to be applied without changes in wheel speed, as can often occur if standard U-joints are used. ● **SEE FIGURE 126–21.**

NOTE: Constant velocity (CV) joints are commonly used on vehicles that have the differential assembly attached to the frame of the vehicle. This design reduces the amount of weight that has to move up and down during suspension movement and helps provide a smooth ride.

TRANSFER CASE SERVICE AND PROBLEM DIAGNOSIS

Four-wheel-drive transfer cases and related components are usually built strong enough for heavy-duty use. However, there is some preventative maintenance that may need to be done:

- **Draining and refilling the transfer case.** Most transfer cases require automatic transmission fluid (ATF), yet some (especially older) units require SAE 80W-90 GL-4 gear lube. Obviously, any fluid leaks should be corrected as soon as

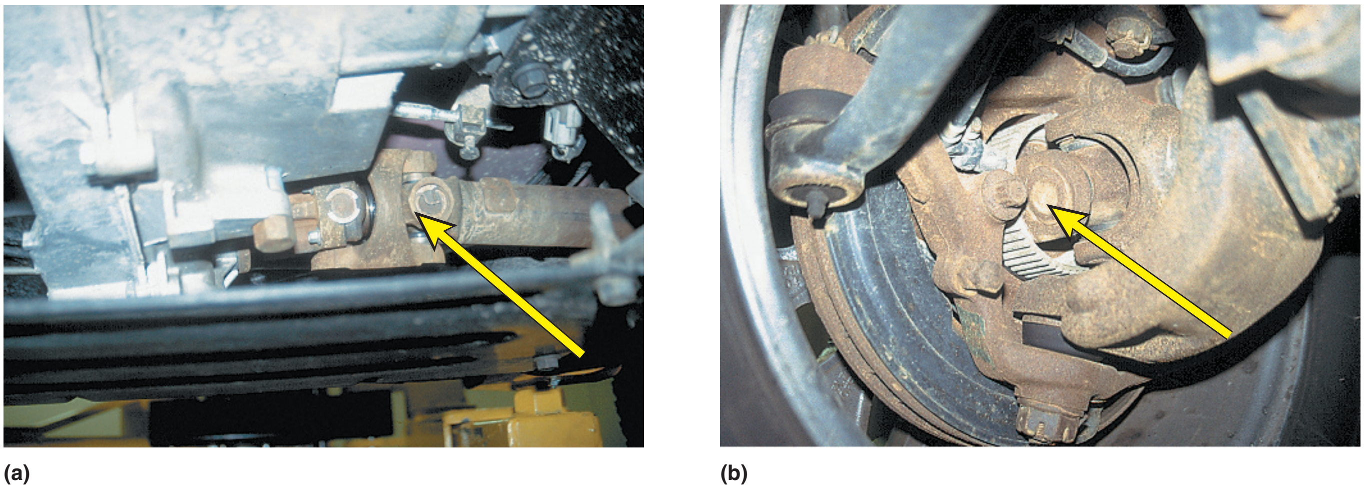

FIGURE 126–20 (a) A standard Cardan U-joint used on the output driveshaft from the transfer case to the front differential assembly. (b) A Cardan-type U-joint at the front drive wheels on a Jeep Wrangler.

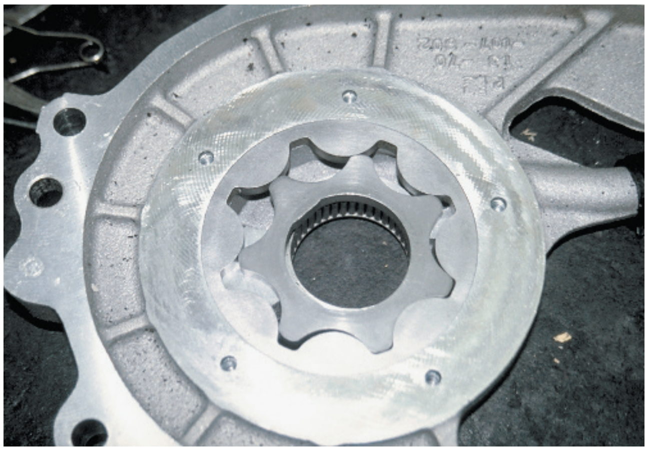

FIGURE 126–22 Most transfer cases use an internal oil pump to force the lubricant throughout the unit. Using the correct lubricant is critical to the proper operation of the transfer case.

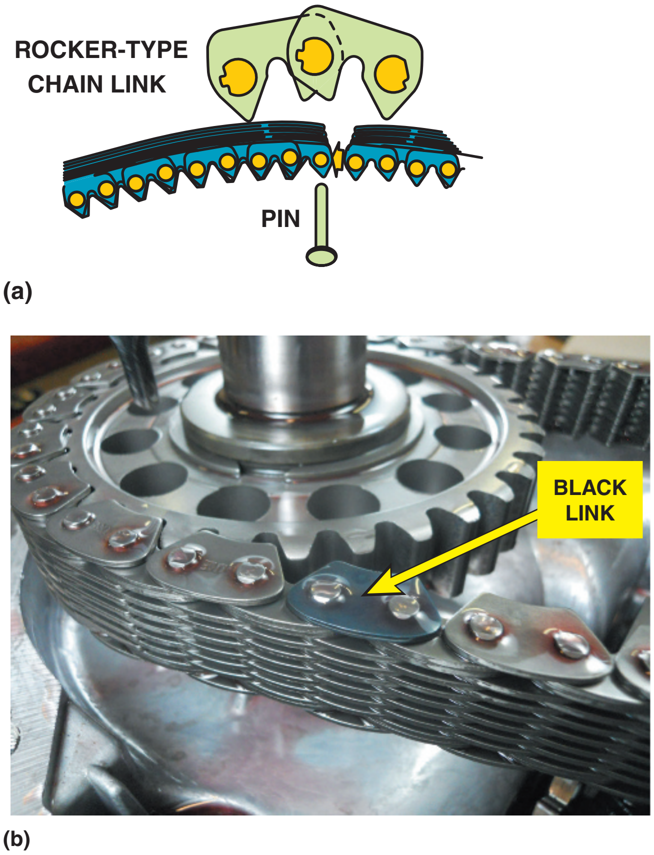

FIGURE 126–23 (a) A pin and rocker-type chain, which is also called a rocker joint-type chain, is used in transfer cases because of low noise and high efficiency, which improves fuel economy. (b) A rocker pin-type chain used in a transfer case.The black link faces upward and is used as an indicator to the service technician to help insure that the chain is replaced in the same side up when it is reassembled.

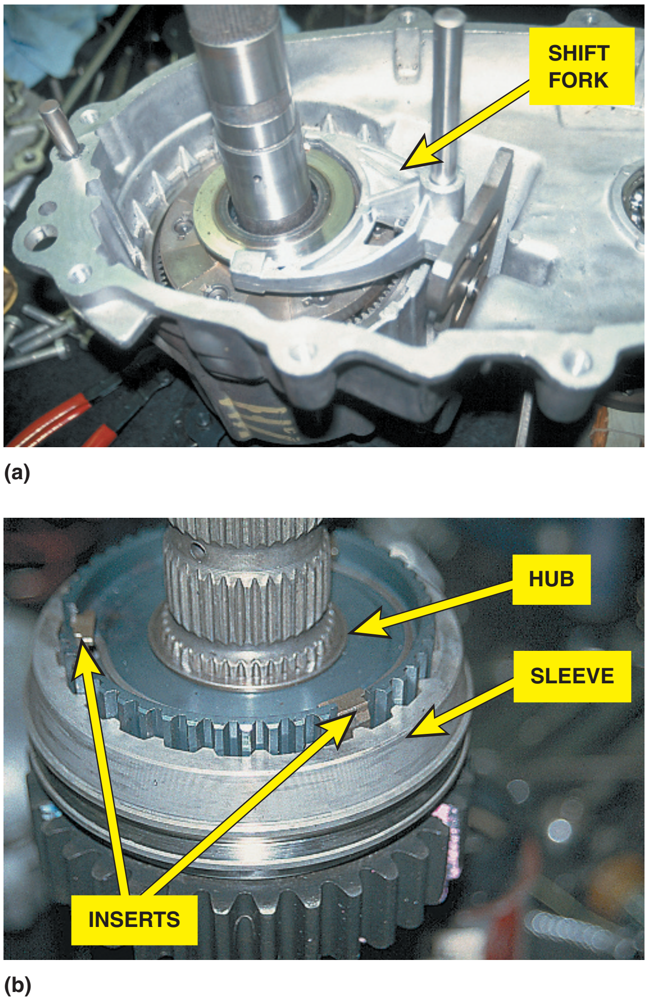

FIGURE 126–24 The transfer case shift forks attach to the synchronizer sleeve. (b) The sleeve, hub, and inserts are similar in design except larger than those used in a manual transmission/transaxle.

possible to avoid damage from low lubricant level. ● **SEE FIGURE 126–22.**

- **Drive chain.** The chain in chain-drive transfer cases can stretch and start hitting the inside of the transfer case. ● **SEE FIGURE 126–23.** This occurs most frequently in vehicles that use four-wheel drive under heavy loads for extended periods of time. The noise the chain makes is very loud, and the chain should be replaced as soon as possible to avoid excessive damage to the case.
- **Bearings.** Transfer case bearings may cause noise whenever the input shaft is rotating even if the transfer case is in neutral. Consult the factory service information for details on transfer case bearing noise diagnosis procedures.
- **Shifting.** Shifting problems can be caused by several items: shift linkage bent or binding, worn shift fork or synchronizer assembly (● **SEE FIGURE 126–24),** incorrect transfer case lubricant.

TECH TIP

Please Install Snap Rings Correctly

Many snap rings are tapered at their opening, as shown in ● **FIGURE 126–25.** This allows the snap ring pliers to grasp the points of the snap ring so that it can be expanded and easily removed. If the points are facing down, it is very difficult for snap-ring pliers to grasp the end of the snap ring. Therefore, to make it easier to disassemble a transfer case later, always install snap rings as they were designed to be installed.

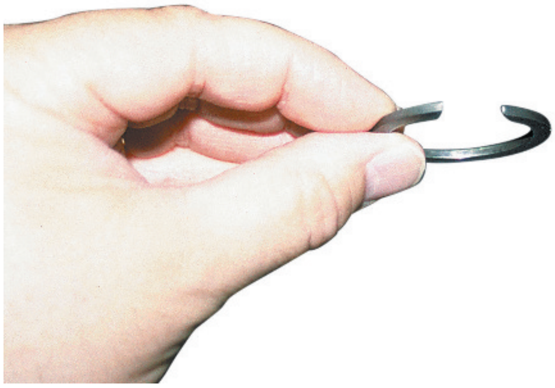

FIGURE 126–25 When reassembling a transfer case (or another automotive component) that includes a snap ring, always be sure that the upper opening is tapered from the top to allow snap-ring pliers room to get a grip on the open end.

NOTE: The transfer case may be difficult to shift if the recommended procedure is not followed. For example, many manufacturers recommend that the vehicle be completely stopped before attempting to make a mode and/or a range shift. Verify proper shifting procedures before further testing or disassembly.

DIAGNOSING AND SERVICING LOCKING HUBS

Locking front hubs should be cleaned periodically, especially if the vehicle has been driven under water or in dusty conditions. Most vehicle manufacturers recommend that the hubs be cleaned and lightly coated with grease at the same time the front wheel bearings are serviced. Check the service information for the exact procedure for the vehicle being serviced. ● **SEE FIGURE 126–26.**

Start the inspection of the front hubs by removing the cover plate. Many problems associated with locking hubs can be corrected by cleaning and lubricating the components. If noise is heard from the hubs, carefully inspect the inner components on both sides of the vehicle. A damaged part can cause noise in the hub on the other side. Service kits are often available for the hubs. These kits contain the gaskets, seals, and retaining rings necessary for installing the hubs correctly after wheel bearing or front brake work has been completed.

TECH TIP

Keep the Differential Vents Clear

All differentials are vented to allow for expansion and contraction of differential lubricant in all temperature ranges. Typically, these vents are shielded openings near the top of the differential. Most trucks, especially four-wheel-drive vehicles, use an extended vent hose to prevent water from getting into the differential if the vehicle is driven in deep water.

If mud gets into the vent, pressure can build up inside the differential and cause lubricant leakage past the rear axle seals. Therefore, whenever replacing rear axle seals, always check to make sure that the differential vent is clear. Remember that four-wheel-drive vehicles use two differentials and that both the front and rear vents plus the vent on the transfer case should be checked.

NOTE: Check the amount of axle end play. Excessive end play caused by defective bearings can cause the drive axle to move enough to damage the hubs.

TRANSFER CASE SERVICE Transfer cases usually require occasional lubricant change during normal service life. However, driver abuse often causes parts to break, requiring the overhaul or replacement of the entire assembly. Always follow the vehicle manufacturer's recommended servicing procedure.

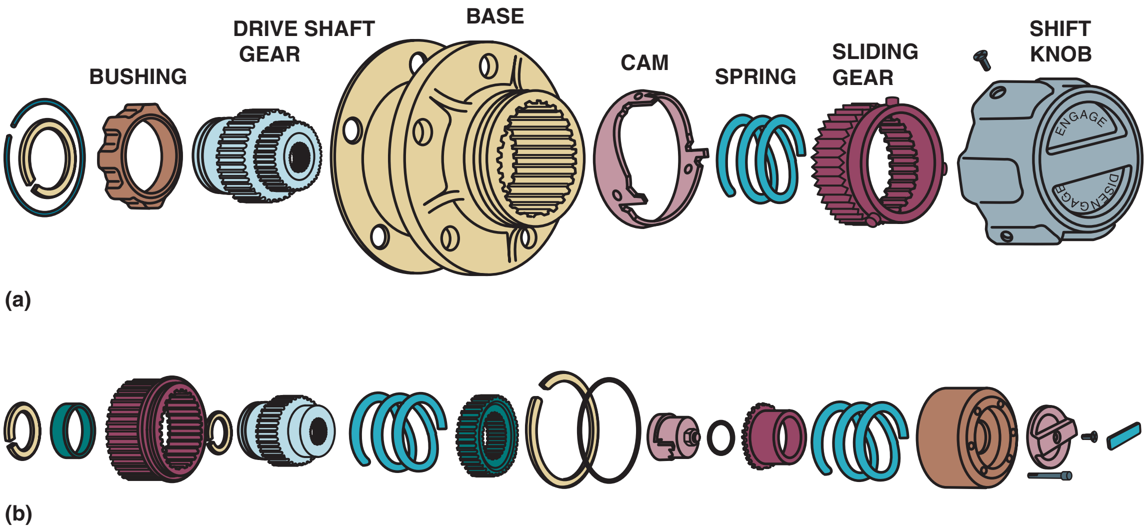

FIGURE 126–26 (a) An exploded view of a Dualmatic® manual locking hub. (b) A Warn® manual locking hub.

CASE STUDY

The Differential Lubricant Story

A four-wheel-drive vehicle was serviced and both differentials were drained and refilled as recommended by the vehicle manufacturer. The owner returned shortly after picking up the vehicle and complained that the vehicle drove as if the parking brake was still applied. The vehicle lacked power and would decelerate rapidly whenever the accelerator pedal was released. Careful inspection of the parking brake revealed that everything was functioning correctly. Because all that was done was the differential fluid service, the fluid level was checked and again, the level was correct and not overfull. Then the technician checked the container of gear lubricant that was used and discovered that the parts store had accidentally sent SAE 80W-140 instead of the requested, and more commonly used, SAE 80W-90. Both lubricants were listed GL-5, meaning that they were acceptable for differentials. The container of lubricant had been installed in the portable lubricating dispenser when it was delivered, and therefore the label on the container was not visible to the technician. The correct lower viscosity lubricant was installed in the differential and normal vehicle performance was restored. The technician and the parts store learned to double-check the product before shipping or using it.

Summary:

Complaint—The customer complained of poor performance after the differential fluid was replaced.
Cause—The incorrect fluid was used.
Correction—the correct viscosity fluid was used, which restored proper vehicle performance.

Chapter 127

VIBRATION AND NOISE DIAGNOSIS AND CORRECTION

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Discuss vibration and noise concerns in vehicles.
- List the procedures for a test-drive when diagnosing vibration/noise problems.
- Explain the vibration speed ranges.
- Explain how to determine the frequency of a vibration.
- Explain ways to diagnose drive-line vibrations and noise.
- Discuss how to find and correct noises.

KEY TERMS:

VIBRATION AND NOISE

NOISE IS A VIBRATION Vibration and noise are two of the most frequent complaints from vehicle owners and drivers. If something is vibrating, it can move air; changes in air pressure (air movement) are what we call noise. Though anything that moves vibrates, wheels and tires account for the majority of vehicle vibration problems. Dampening weights are fastened to engines or transmissions in an effort to minimize noise, vibration, and harshness (called **NVH**).

If a new vehicle has a vibration or noise problem, then the most likely cause is an assembly or parts problem. This is difficult to diagnose because the problem could be almost anything, and a careful analysis procedure should be followed as outlined later in this chapter.

If an older vehicle has a vibration or noise problem, the first step is to question the vehicle owner as to when the problem first appeared. Some problems and possible causes include the following:

Problem	Possible Causes
Vibration at idle	Engine mount could be defective or not reinstalled correctly after an engine or transmission repair.
Noise/vibration	Exhaust system replacement or repair. ● **SEE FIGURE 127–1**.

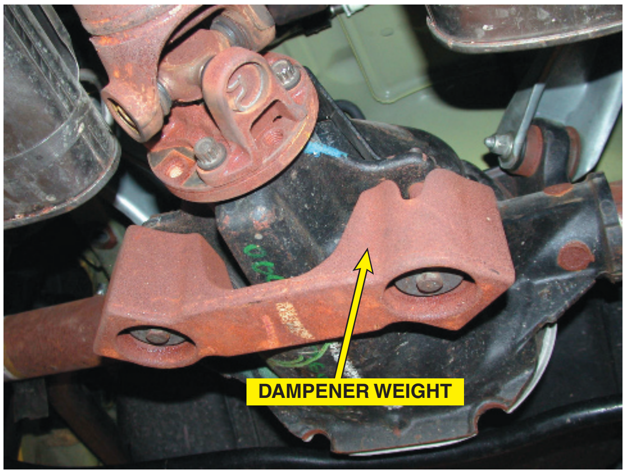

FIGURE 127–1 Many vehicles, especially those equipped with four-cylinder engines, use a dampener weight attached to the exhaust system or differential, as shown, to dampen out certain frequency vibrations.

NOTE: A typical exhaust system can "grow" or lengthen up to 2 inches (1 cm) when warm compared with room temperature. Always inspect an exhaust system when warm, if possible, being careful to avoid being burned by the hot exhaust components.

CASE STUDY

The Vibrating Ford Transmit Connect

The owner of a Ford Transit Connect complained of a severe vibration at idle. The technician checked for any stored diagnostic trouble codes (DTCs) and any related technical service bulletins (TSBs) and found a TSB that the lower engine mount could be the cause. The transmission (powertrain) mount was found to be cracked so this was also replaced. The vibration was still present. Thinking that the engine mounts could be an issue the technician found them to be clean without any leaks or cracks. Checking with other technicians on www.iatn.net resulted in several responses that suggested that the upper mount, being fluid (gel) filled, has been found to be the cause of a vibration even if it is not leaking. Taking the advice of other technicians who have solved a vibration by replacing the upper mount, the technician did replace it and this corrected the vibration concern.

Apparently the failed engine mounts caused the engine to vibrate because they were not in the original position where they were designed to dampen engine noise and vibrations.

Summary:

Complaint—The owner complained of a vibration in the engine when at idle speed only.
Cause—Defective engine mounts including the upper liquid filled mount were found to be the root cause.
Correction—All three engine (powertrain) mounts were replaced based on a TSB and a visual inspection, plus advice from other service technicians.

Vibration at higher vehicle speeds	Incorrect driveshaft angles could be the result of a change in the U-joints, springs, transmission mounts, or anything else that can cause a change in driveshaft angles.
Noise over rough roads	Exhaust system or parking brake cables are often causes of noise while driving over rough road surfaces. ● **SEE FIGURE 127–2.** Defective shock absorbers or shock absorber mountings are also a common cause of noise.

TEST-DRIVE

The first thing a technician should do when given a vibration or noise problem to solve is to duplicate the condition. This means the technician should drive the vehicle and observe when and where the vibration is felt or heard. See the chart in ● **FIGURE 127–3**.

Though there are many possible sources of a vibration, some simple observations may help to locate the problem quickly:

1. If the vibration is felt or seen in the steering wheel, dash, or hood of the vehicle, the problem is most likely to be caused by defective or out-of-balance *front* wheels or tires. ● **SEE FIGURE 127–4.**

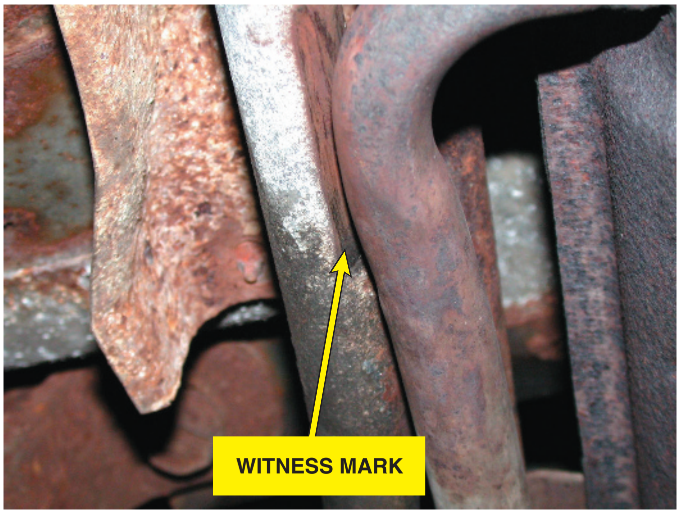

FIGURE 127–2 The exhaust was found to be rubbing on the frame rail during a visual inspection. Rubber exhaust system hangers are used to isolate noise and vibration from the exhaust system from entering the interior. These rubber supports can fail, causing the exhaust system to be out of proper location. It was found by looking for evidence of **witness marks**.

2. If the vibration is felt in the seat of the pants or seems to be all over the vehicle, the problem is most likely to be caused by defective or out-of-balance *rear* wheels or tires. In a rear-wheel-drive vehicle, the driveshaft (propeller shaft) and related components might also be the cause.

While on the test-drive, try to gather as much information about the vibration or noise complaint as possible.

STEP 1 Determine the vehicle speed (MPH or km/h) or engine speed (RPM) where the vibration occurs. Drive on a smooth, level road and accelerate up to highway speed, noting the vehicle speed or speeds at which the vibration or noise occurs.

STEP 2 To help pin down the exact cause of the vibration, accelerate to a speed slightly above the point of maximum vibration. Shift the vehicle into neutral and allow it to coast down through the speed of maximum vibration.

TECH TIP

The Duct Tape Trick

A clicking noise heard at low speeds from the wheels is a common noise complaint. This noise is usually most noticeable while driving with the windows lowered. This type of noise is caused by loose disc brake pads or noisy wheel covers. To confirm exactly what is causing the noise, simply remove the wheel covers and drive the vehicle. If the clicking noise is still present, check the brakes and wheels for faults. If the noise is gone with the wheel covers removed, use duct tape over the inner edge of the wheel covers before installing them onto the wheels. The duct tape will cushion and dampen the wheel cover and help reduce the noise. The sharp prongs of the wheel cover used to grip the wheel will pierce through the duct tape and still help retain the wheel covers.

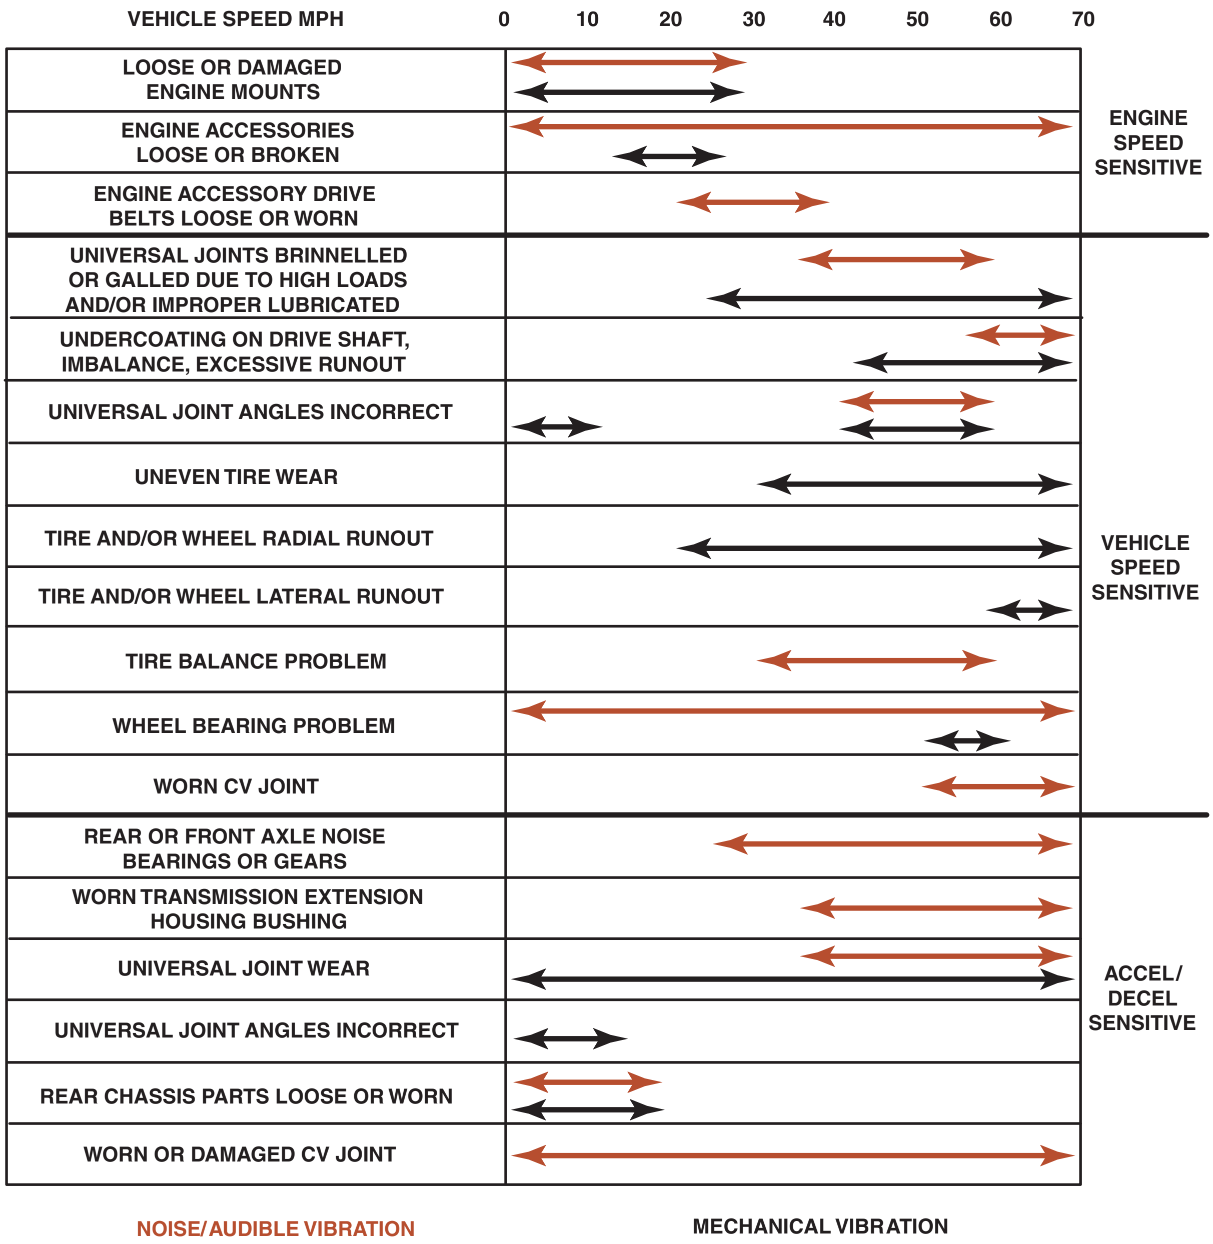

FIGURE 127–3 A chart showing the typical vehicle and engine speeds at which various components will create a noise or vibration and under what conditions.

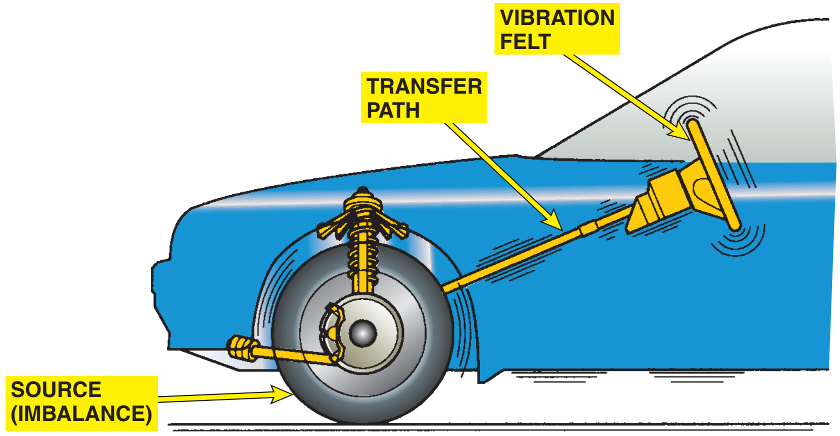

VIBRATION FELT
TRANSFER PATH
SOURCE (IMBALANCE)

FIGURE 127–4 Vibration created at one point is easily transferred to the passenger compartment. MacPherson strut suspensions are more sensitive to tire imbalance than SLA-type suspensions.

If the vibration still exists, then the cause of the problem could be wheels, tires, or other rotating components, *except* the engine.

If the vibration is eliminated when shifted out of gear, the problem is related to the engine or transmission.

NOTE: If the engine or transmission has been removed from the vehicle, such as during a clutch replacement, carefully observe the location and condition of the mounts. If an engine or transmission mount is defective or out of location, engine and driveline vibrations are often induced and transmitted throughout the vehicle.

NEUTRAL RUN-UP TEST The **neutral run-up test** is used to determine if the source of the vibration is engine-related. With the transmission in Neutral or Park, slowly increase the engine RPM and with a tachometer, observe the RPM at which the vibration occurs. *Do Not Exceed the Manufacturer's Recommended Maximum Engine RPM.*

If the fault is found in the engine itself, further engine testing is needed to find the root cause.

VIBRATION DURING BRAKING A vibration during braking usually indicates out-of-round brake drums, warped disc brake rotors, or other braking system problems. The *front* rotors are the cause of the vibration if the steering wheel is also vibrating (moving) during braking. The *rear* drums or rotors are the cause of the vibration if the vibration is felt throughout the vehicle and brake pedal, but *not* the steering wheel. Another way to check if the vibration is due to rear brakes is to use the parking brake to stop the vehicle. If a vibration occurs while using the parking brake, the rear brakes are the cause.

NOTE: Wheels should *never* be installed using an air impact wrench. Even installation torque is almost impossible to control, and overtightening almost always occurs. The use of impact wrenches causes the wheel, hub, and rotor to distort, resulting in vibrations and brake pedal pulsations. Always tighten wheel lugs in the proper sequence and with proper torque value, using a torque wrench or torque-limiting adapter bars.

VIBRATION SPEED RANGES

FREQUENCY *Vibration* describes an oscillating motion around a reference position. The number of times a complete motion cycle takes place during a period of one second is called **frequency** and is measured in **hertz (Hz)** (named for Heinrich R. Hertz, a nineteenth-century German physicist). ● **SEE FIGURES 127–5 AND 127–6**.

The unit of measure for frequency was originally cycles per second (CPS). This was changed to hertz in the 1960s.

To help understand frequency, think of the buzzing sound made by some fluorescent light fixtures. That 60 Hz hum is the same frequency as the alternating current. A 400 Hz sound is high pitched. In fact, most people can only hear sounds between 20 and 15,000 Hz. Generally, low-frequency oscillations between 1 and 80 Hz are the most disturbing to vehicle occupants.

VIBRATION ORDER **Vibration order** is the number of vibrations created in one revolution of a component. A single high spot on a tire, for example, will cause one bump per revolution, which is a first-order vibration. If the tire rotates 10 times per

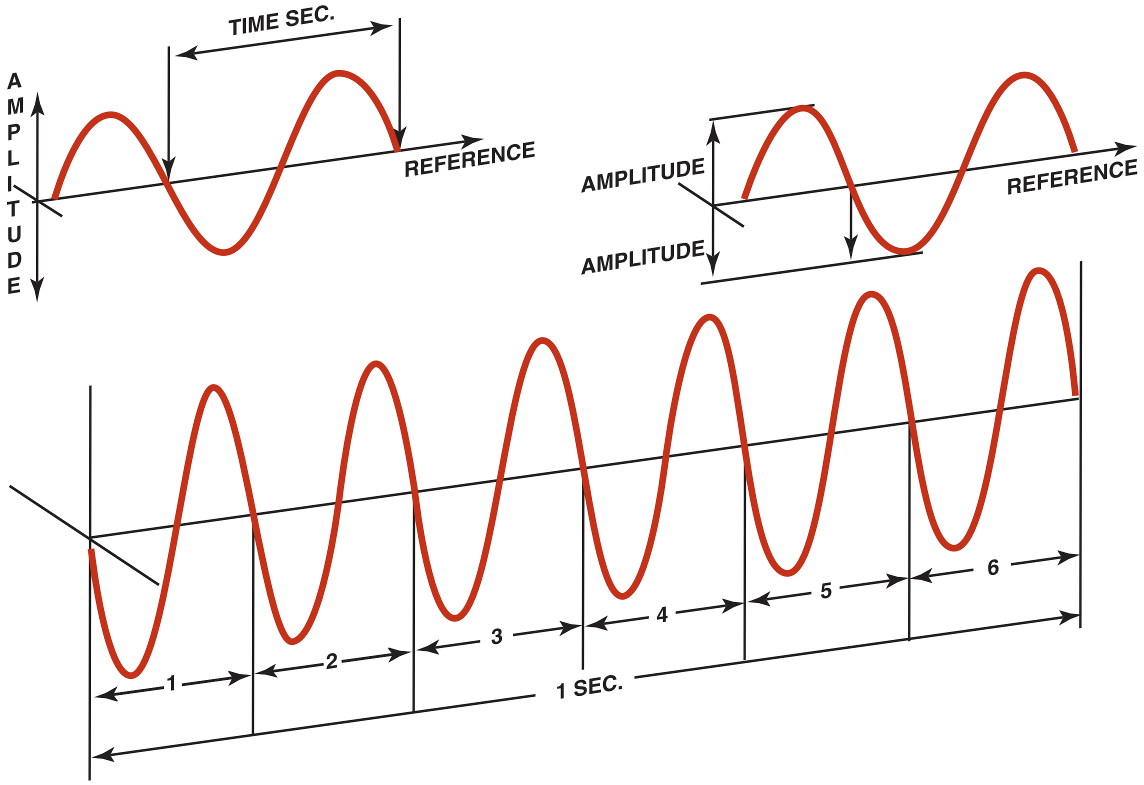

FIGURE 127–5 Hertz means *cycles* per *second*. If six cycles occur in one second, then the frequency is 6 Hz. The amplitude refers to the total movement of the vibrating component.

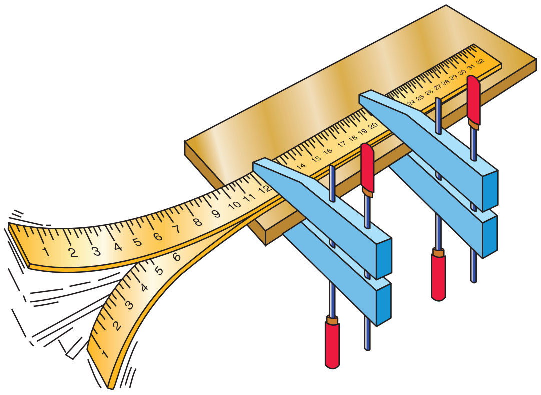

FIGURE 127–6 Every time the end of a clamped yardstick moves up and down, it is one cycle. The number of cycles divided by the time equals the frequency. If the yardstick moves up and down 10 times (10 cycles) in two seconds, the frequency is 5 Hz (10 ÷ 2 = 5).

CASE STUDY

S-10 Pickup Truck Frame Noise

The owner of a Chevrolet S-10 pickup truck complained of a loud squeaking noise, especially when turning left. Several technicians attempted to solve the problem and replaced shock absorbers, ball joints, and control arm bushings without solving the problem. The problem was finally discovered to be the starter motor hitting the frame. A measurement of new vehicles indicated that the clearance between the starter motor and the frame was about 1/8 inch (0.125 in.) (0.3 cm)! The sagging of the engine mount and the weight transfer of the engine during cornering caused the starter motor to rub up against the frame. The noise was transmitted through the frame throughout the vehicle and made the source of the noise difficult to find.

Summary:

Complaint—Owner complained of a loud squeaking noise.
Cause—The starter was found to be hitting the frame due to a collapsed engine mount.
Correction—Both engine mounts were replaced, which proved to be the root cause.

second, there are 10 disturbances per second, which is also called a first-order vibration of 10 Hz. If there are two bumps on a tire, a second-order vibration is created that would generate a vibration of 20 Hz if the tire were rotating 10 times per second.

TIRE AND WHEEL VIBRATIONS Typical vehicle components that can cause vibration in specific frequency ranges at 50 MPH (80 km/h) include the following:

LOW FREQUENCY (5–20 HZ) This frequency range of vibration is very disturbing to many drivers because this type of vibration can be seen and felt in the steering wheel, seats, mirrors, and other components. Terms used to describe this type of vibration include *nibble*, *shake*, *oscillation*, *shimmy*, and *shudder*.

Tires and wheels are the most common source of vibration in the low-frequency range. To determine the *exact* frequency for the vehicle being checked, the following formula and procedure can be used.

CASE STUDY

The Vibrating Van

After the engine was replaced in a rear-wheel-drive van, a vibration that felt like an engine miss was noticed by the driver. Because the vibration was not noticed before the engine was replaced, the problem was thought to be engine-related. Many tests failed to find anything wrong with the engine. Even the ignition distributor was replaced, along with the electronic ignition module, on the suspicion that an ignition misfire was the cause.

After hours of troubleshooting, a collapsed transmission mount was discovered. After replacing the transmission mount, the "engine miss" and the vibration were eliminated. The collapsed mount caused the driveshaft U-joint angles to be unequal, which caused the vibration.

Summary:

Complaint—Owner complained of a vibration during acceleration only that was believed to be an ignition misfire.
Cause—The transmission mount was found to have collapsed, which affected the driveshaft angles.
Correction—The transmission mount was replaced, which restored the proper driveshaft angles.

Tire rolling frequency is calculated as follows:

$$\text{Hz} = \frac{\text{MPH} \times 1.47}{\text{tire circumference in ft}}$$

This formula works for all vehicles regardless of tire size. The circumference (distance around the tread) can be measured by using a tape measure around the tire. The **rolling circumference** of the tire is usually shorter due to the contact patch. To determine the rolling circumference, follow these easy steps:

STEP 1 Inflate the tire(s) to the recommended pressure. Park the vehicle with the valve stem pointing straight down and mark the location on the floor directly below the valve stem.

STEP 2 Slowly roll the vehicle forward (or rearward) until the valve stem is again straight down. Mark the floor below the valve stem.

STEP 3 Measure the distance between the marks in feet. ● **SEE FIGURE 127–7**. To change inches to feet, divide by 12 (e.g., 77 in. divided by 12 in. = 6.4 ft). To determine the rolling frequency of this tire at 60 MPH, use 6.4 ft as the tire circumference in the formula.

$$\text{Frequency} = \frac{60\ \text{MPH} \times 1.47}{6.4\ \text{ft}} = 13.8\ \text{Hz}$$

NOTE: Tire circumference is critical on four-wheel-drive vehicles. The transfer case can be damaged and severe vibration can occur if the rolling circumference is different by more than 0.6 inch (15 mm) on the same axle, or more than 1.2 inch (30 mm) front to rear.

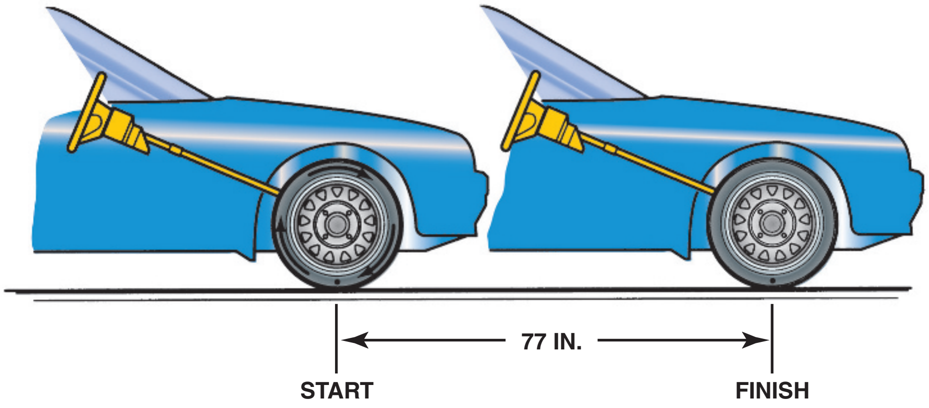

FIGURE 127–7 Determining the rolling circumference of a tire.

DRIVELINE VIBRATIONS

MEDIUM FREQUENCY (20–50 HZ) This frequency range of vibrations may also be described as a shake, oscillation, or shimmy. These higher frequencies may also be called *roughness* or *buzz. Components become blurred and impossible to focus on above a vibration of 30 Hz.*

ENGINE-RELATED VIBRATIONS

HIGH FREQUENCY (50–100 HZ) Vibrations in this range may also be *heard* as a moan or hum. The vibration is high enough that it may be felt as a numbing sensation that can put the driver's hands or feet to sleep. Engine-related vibrations vary with engine speed, regardless of road speed. Frequency of the vibration from an engine is determined from the engine speed in revolutions per minute (RPM).

$$\text{Frequency in Hz} = \frac{\text{engine RPM}}{60}$$

For example, if a vibration occurs at 3,000 engine RPM, then the frequency is 50 Hz.

$$\text{Hz} = \frac{3{,}000 \text{ RPM}}{60} = 50 \text{ Hz}$$

VIBRATION FREQUENCY

MEASURING FREQUENCY Knowing the frequency of the vibration greatly improves the speed of tracking down the source of the vibration. Vibration can be measured using a reed tachometer or an **electronic vibration analyzer (EVA).** ● **SEE FIGURE 127–8.**

A reed tachometer is placed on the dash, console, or other suitable location inside the vehicle. The vehicle is then driven on a smooth, level road at the speed where the vibration is felt the most. The reeds of the reed tachometer vibrate at the frequency of the vibration.

NOTE: Other types of vibration diagnostic equipment may be available from vehicle or aftermarket manufacturers.

CORRECTING LOW-FREQUENCY VIBRATIONS A low-frequency vibration (5–20 Hz) is usually due to tire/wheel problems, including the following:

1. Tire and/or wheel imbalance. ● **SEE FIGURES 127–9 THROUGH 127–11.**
2. Tire and/or wheel radial or lateral runout.

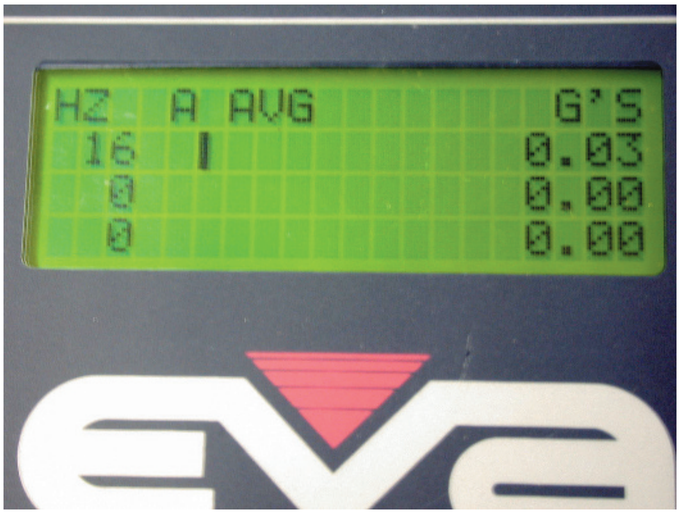

FIGURE 127–8 An electronic vibration analyzer.

3. Radial force variation within the tire itself.
4. If front-wheel drive, a bent or damaged drive axle joint or shaft.
5. Warped rotors.

Tires that are out of round or defective will be most noticeable at low speeds, will get better as speed increases, and then will vibrate again at highway speeds.

Tires that are out of balance will tend not to be noticeable at low speeds and will be most noticeable at highway speeds.

NOTE: High-performance tires are manufactured with different carcass and belt package angles as well as a stiffer, harder tread rubber compound than standard tires. While these construction features produce a tire that allows sporty handling, the tire itself causes a stiff ride, often with increased tire noise. High-performance tires also generate and transmit different frequencies than regular tires. Using replacement high-performance tires on a vehicle not designed for this type of tire may create noise and vibration concerns for the driver/owner that the technician cannot correct.

CORRECTING MEDIUM-FREQUENCY VIBRATIONS Medium-frequency vibrations (20–50 Hz) can be caused by imbalances of the driveline as well as such things as the following:

1. Defective U-joints. Sometimes an old or a newly installed U-joint can be binding. This binding of the U-joint can cause

TECH TIP

Squeaks and Rattles

Many squeaks and rattles commonly heard on any vehicle can be corrected by tightening all bolts and nuts you can see. Raise the hood and tighten all fender bolts. Tighten all radiator support and bumper brackets. Open the doors and tighten all hinge and body bolts.

An even more thorough job can be done by hoisting the vehicle and tightening all under-vehicle fasteners, including inner fender bolts, exhaust hangers, shock mounts, and heat shields. It is amazing how much this quiets the vehicle, especially on older models. It also makes the vehicle feel more solid with far less flex in the body, especially when traveling over railroad crossings or rough roads.

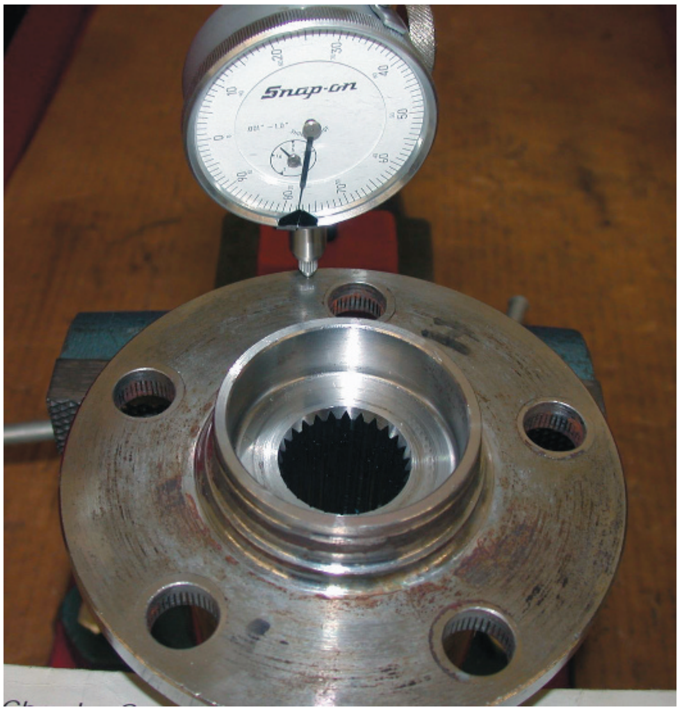

FIGURE 127–11 Another cause of a vibration that is often blamed on wheels or tires is a bent bearing hub. Use a dial indicator to check the flange for runout.

a vibration. Often a blow to the joint with a brass hammer can free a binding U-joint. This is often called *relieving the joint*. Tapping the joint using a brass punch and a hammer also works well.

2. Driveshaft imbalance (such as undercoating on the driveshaft) or excessive runout.
3. Incorrect or unequal driveshaft angles.

Driveline vibrations are usually the result of an imbalance in the rotating driveshaft (propeller shaft) assembly.

The driveshaft of a typical rear-wheel-drive (RWD) vehicle rotates at about three times the speed of the drive wheels. The differential gears in the rear end change the direction of the power flow from the engine and driveshaft, as well as provide for a gear reduction.

Front-wheel-drive (FWD) vehicles do not have medium-frequency vibration caused by the driveshaft because the differential is inside the transaxle and the drive axle shafts rotate at the same speed as the wheels and tires.

All driveshafts are balanced at the factory, and weights are attached to the driveshaft, if necessary, to achieve proper balance. A driveshaft should be considered one of the items checked if the medium-frequency vibration is felt throughout the vehicle or in the seat of the pants.

NOTE: If a vibration is felt during heavy acceleration at low speeds, a common cause is incorrect universal joint angles. This often happens when the rear of the vehicle is heavily loaded or sagging due to weak springs. If the angles of the U-joints are not correct (excessive or unequal from one end of the driveshaft to the other), a vibration will also be present at higher speeds and is usually torque-sensitive.

CORRECTING HIGH-FREQUENCY VIBRATIONS High-frequency vibrations (50–100 Hz) are commonly caused by a fault of the clutch, torque converter, or transmission main shaft that rotates at engine speed; in the engine itself, they can be caused by items such as the following:

1. A defective spark plug wire
2. A burned valve
3. Any other mechanical fault that will prevent any one or more cylinders from firing correctly
4. A defective harmonic balancer

If the engine is the cause, run in Neutral at the same engine speed. If the vibration is present, perform a complete engine condition diagnosis. Some engines only misfire under load and will not vibrate while in Neutral without a load being placed on the engine, even though the engine is being operated at the same speed (RPM).

Exhaust system pulses occur at the following conditions:

4-cylinder engine	2 × engine RPM
6-cylinder engine	3 × engine RPM
8-cylinder engine	4 × engine RPM

If the exhaust system is touching the body, it will transfer these pulses as a vibration. Exhaust system vibrations vary with engine speed and usually increase as the load on the engine increases.

DRIVELINE DIAGNOSIS

CORRECTING DRIVELINE ANGLES Incorrect **driveline angles** are usually caused by one or more of the following:

1. Worn, damaged, or improperly installed U-joints.
2. Worn, collapsed, or defective engine or transmission mount(s).
3. Incorrect vehicle ride height. (As weight is added to the rear of a rear-wheel-drive vehicle, the front of the differential rises and changes the working angle of the rear U-joint.)
4. Bent or distorted driveshaft.

CHECKING DRIVESHAFT RUNOUT Check to see that the driveshaft is not bent by performing a **driveshaft runout** test using a dial indicator. Runout should be measured at three places along the length of the driveshaft.

The maximum allowable runout is 0.030 inch (0.8 mm). If runout exceeds 0.030 inch, remove the driveshaft from the rear end and reindex the driveshaft onto the **companion flange** at 180 degrees from its original location. Remeasure the driveshaft runout. If the runout is still greater than 0.030 inch, the driveshaft is bent and needs replacement *or* the companion flange needs replacement. ● **SEE FIGURE 127–12**.

MEASURING DRIVESHAFT U-JOINT PHASING Measuring driveshaft U-joint phasing involves checking to see if the front and rear U-joints are directly in line or parallel with each other. With the vehicle on a drive-on lift, or if using a frame-contact hoist, support the weight of the vehicle on stands placed under the rear axle. Place an inclinometer on the front U-joint bearing cup and rotate the driveshaft until horizontal; note the inclinometer reading. Move the inclinometer to the rear U-joint. The angles should match. If the angles are not equal, the driveshaft is out of phase and should be replaced. Incorrect phasing is usually due to a twisted driveshaft or an incorrectly welded end yoke.

CHECKING COMPANION FLANGE RUNOUT The companion flange is splined to the rear axle pinion shaft and provides the mounting for the rear U-joint of the driveshaft. Two items should be checked on the companion flange while diagnosing a vibration:

1. The companion flange should have a maximum runout of 0.006 inch (0.15 mm) while being rotated. If the flange was pounded off with a hammer during a previous repair, the deformed flange could cause a vibration.

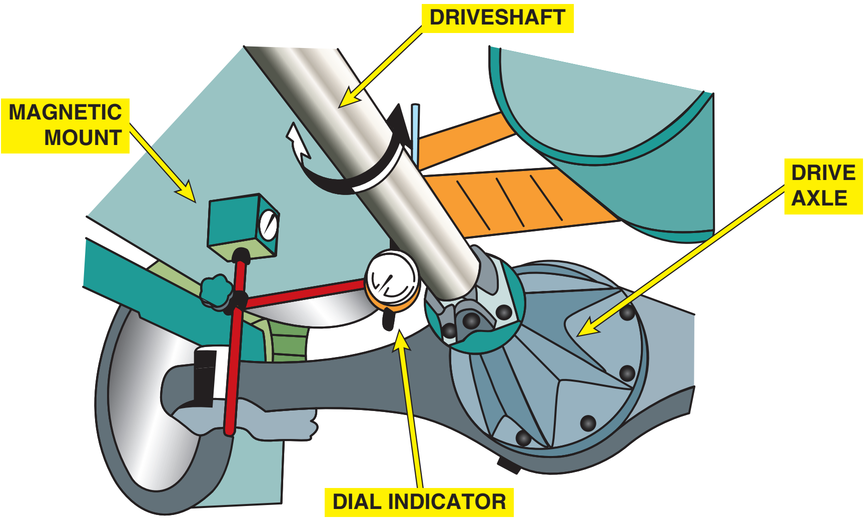

FIGURE 127–12 Checking a driveshaft for runout using a magnetic mounted dial indicator.

2. Check the companion flange for a missing balance weight. Many flanges have a balance weight that is spot-welded onto the flange. If the weight is missing, a driveline vibration can result.

BALANCING THE DRIVESHAFT If the driveshaft (propeller shaft) is within runout specification and a vibration still exists, the balance of the shaft should be checked and corrected as necessary.

The procedure for testing driveshaft balance using a strobe balancer includes the following:

NOTE: Driveshaft balance is more important than front drive axle shaft balance because a driveshaft rotates much faster. A typical driveshaft rotates about three times faster than the drive wheels due to the gear reduction in the differential. Drive axle shafts rotate at the same speed as the drive wheels.

STEP 1 Raise the vehicle and mark the driveshaft with four equally spaced marks around its circumference. Label each mark with a 1, 2, 3, and 4. ● **SEE FIGURE 127–13**.

STEP 2 Attach the strobe balancer sensor to the bottom of the differential housing as close to the companion flange as possible. ● **SEE FIGURE 127–14**.

NOTE: The sensor does not rotate with the driveshaft but picks up the vibration of the driveshaft through the differential housing.

STEP 3 With the vehicle securely hoisted and the drive wheels off the ground, start the engine and put the transmission into gear to allow the drive wheels to rotate.

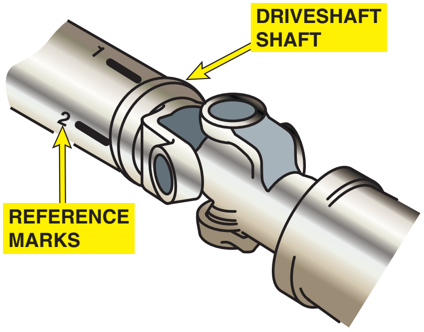

FIGURE 127–13 When checking the balance of a driveshaft, make reference marks around the shaft so that the location of the unbalance may be viewed when using a strobe light.

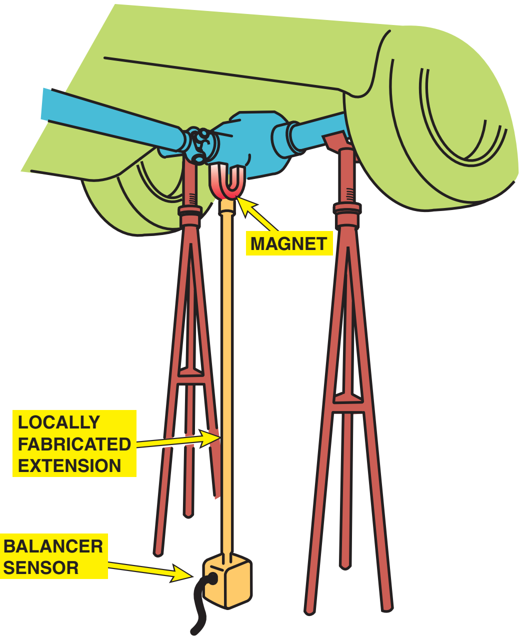

NOTE: LOCALLY FABRICATED EXTENSION FOR BALANCER PICKUP CONSISTS OF 3/8 IN. TUBE AND COMPRESSION FITTINGS

FIGURE 127–14 Using a strobe balancer to check for driveline vibration requires that an extension be used on the magnetic sensor. Tall safety stands are used to support the rear axle to keep the driveshaft angles the same as when the vehicle is on the road.

STEP 4 Hold the strobe light close to the marks on the driveshaft.

a. If the light does *not* flash, the driveshaft is balanced and no corrective action is necessary.

b. If the light *does* flash, observe what number mark is shown by the flashing light.

STEP 5 Apply hose clamps so that the screw portion of the clamp(s) is *opposite* the number seen with the strobe light. The screw portion of the hose clamp is the corrective weight. Remember, the strobe light sensor was mounted to the *bottom* of the differential housing. The strobe light flashes when the heavy part of the driveshaft is facing *downward.* If the heavy part of the driveshaft is down, then corrective weight must be added to the opposite side of the driveshaft. ● **SEE FIGURES 37–15 AND 37–16**.

NOISE

NOISE DIAGNOSIS Noise diagnosis is difficult because a noise is easily transmitted from its source to other places in the vehicle. For example, if a rear shock absorber mount is loose, the noise may be heard as coming from the middle or even the front of the vehicle. As the axle moves up and down, the noise is created where metal touches metal between the shock absorber bolt and the axle shock mount. The noise is then transmitted throughout the frame of the vehicle, and therefore causes the sound to appear to come from "everywhere." To help pin down the exact location of the sound, perform a thorough test-drive, including driving beside parked vehicles or walls with the vehicle windows open. (See the following chart for driveline and bearing-type noise diagnosis.)

Some noises may be normal; a similar vehicle should be driven and compared before replacing parts that may not be defective. Noises usually become louder and easier to find as time and mileage increase. An occasional noise usually becomes a constant noise.

CASE STUDY

Everything Is OK until I Hit a Bump

The owner of an eight-year-old vehicle asked that the vibration in the steering wheel be repaired. It seemed that the vehicle drove fine until the front wheels hit a bump in the road—then the steering wheel shimmied for a few seconds.

This problem is typical of a vehicle with excessive steering linkage freeplay. When driving straight, centrifugal (rolling) force on the tires tends to force the front wheels outward (toe-out). When one or both wheels hit a bump, the play in the linkage becomes apparent, causing the steering wheel to shimmy until the rolling force again equalizes the steering.

The service technician performed a test-drive and a careful steering system inspection and discovered freeplay in both inner tie rod end sockets of the rack-and-pinion unit. The steering unit also had some power steering leakage at the tie rod bellows. A replacement remanufactured power-rack-and-pinion steering unit was recommended to the customer. The customer approved the replacement rack and authorized the required realignment. A careful test-drive confirmed that the problem was corrected.

Summary:

Complaint—Owner complained of vibration but only after hitting a bump in the road.
Cause—The rack-and-pinion steering had excessive looseness in both the inner and outer tie rods.
Correction—The steering gear assembly was replaced and the problem was corrected.

NOISE CORRECTION The proper way to repair a noise is to repair the cause. Other methods that have been used by technicians include the following:

1. Insulating the passenger compartment to keep the noise from the passengers.
2. Turning up the radio!

While these methods are usually inexpensive, the noise is still being generated, and if a noisy bearing or other vehicle component is not corrected, more expensive damage is likely to occur. Always remember: *Almost all vehicle faults cause noise first—do not ignore the noise because it is the early warning signal of more serious and possibly dangerous problems*.

Some of the things that can be done to correct certain vibrations and noise include the following:

1. Check all power steering high-pressure lines, being certain that they do not touch any part of the body, frame, or engine except where they are mounted.
2. Carefully check, tighten, and lubricate the flexible couplings in the exhaust system. Use a drive-on lift to ensure normal suspension positioning to check the exhaust system clearances. Loosen, then tighten, all exhaust clamps and hangers to relieve any built-up stress.
3. Lubricate all rubber bushings with rubber lube and replace any engine or transmission mounts that are collapsed.
4. Replace and/or tighten all engine drive belts and check that all accessory mounting brackets are tight.

FREQUENTLY ASKED QUESTION

What Is "Chassis Ears"?

Chassis ears is a brand name for a tool that uses microphones that can be attached to parts under the vehicle and transmit noise to a receiver. The receiver can be tuned so that a technician can listen to one microphone at a time while someone else is driving. This tool makes finding the source of a noise easier.
● **SEE FIGURE 127–19**.

Noise	Diagnostic Procedure
Tire noise	Change tire pressure; if no change, then the problem is not tires but bearings, or other components. Drive on various road surfaces—smooth asphalt reduces tire noise. Rotate the tires front to rear, if possible. Various tread designs can cause added noise (● **SEE FIGURE 127–17**).
Engine/exhaust noise	Operate the engine at various speeds and loads. Drive faster than the speed where the noise occurs, place the transmission in Neutral, and "coast" down through the speed of maximum noise. Determine if the engine speed or vehicle speed is the cause of the noise.
Wheel bearing noise (● **SEE FIGURE 127–18**)	Drive the vehicle slowly on a smooth road. Make left and right turns with the vehicle. Wheel bearing noise changes as weight is transferred side to side. If noise occurs when turning to the right, then the left bearing is the cause. if noise occurs when turning to the left, then the right bearing is the cause. Hoist the vehicle and rotate the wheel by hand to verify the roughness.
Differential side bearing noise	Drive the vehicle slowly on a smooth road. Differential bearing noise is a low-pitch noise that does not change when turning. The noise varies with vehicle speed.
Differential pinion bearing noise	A whine noise increases with the vehicle speed. Drive on a smooth road and accelerate, coast, and hold a steady speed (float). A defective front pinion bearing may be louder on acceleration. A defective rear pinion bearing may be louder on deceleration. Pinion bearing noise usually peaks in a narrow speed range.
U-joint noise	Drive slowly on a smooth road surface. Drive in reverse and forward. U-joints usually make a "chirp, chirp, chirp" noise in reverse because of lack of lubrication and brinelling from driving forward. Driving in reverse changes the force on the needle bearings in the U-joint, and noise is created.
Clutch noise	**Transmission input bearing:** Start the engine with the transmission in Neutral and the parking brake set. The clutch should be engaged (foot off the clutch pedal). If the bearing noise is heard, the transmission input bearing is the source. **Release (throw-out) bearing:** Start the engine with the transmission in Neutral and the parking brake set. Lightly depress the clutch pedal just enough to take up freeplay (usually 1 in. or less). If the noise is now heard, the source is the release (throw-out) bearing as the clutch fingers make contact with the bearing. **Pilot bearing:** Start the engine with the transmission in Neutral and the parking brake set. Push the clutch pedal fully to the floor (disengage the clutch). If the bearing noise is heard with the clutch disengaged, it is caused by the pilot bearing.

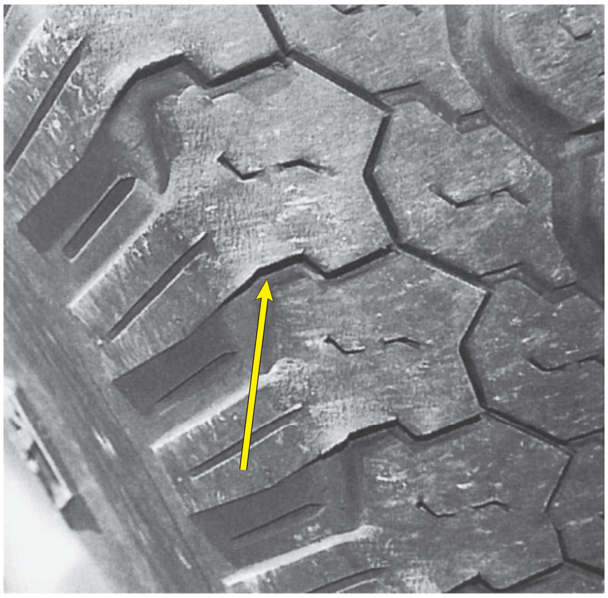

FIGURE 127–17 Tire wear caused by improper alignment or driving habits, such as high-speed cornering, can create tire noise. Notice the feather-edged outer tread blocks.

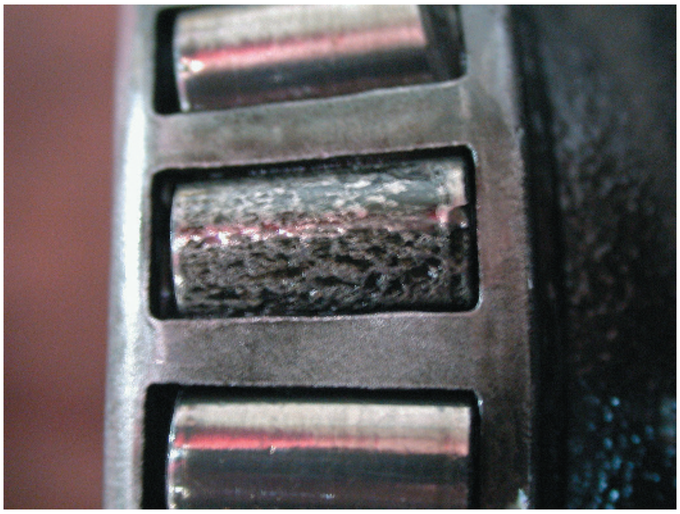

FIGURE 127–18 This bearing was found on a vehicle that had been stored over the winter. This corroded bearing produced a lot of noise and had to be replaced.

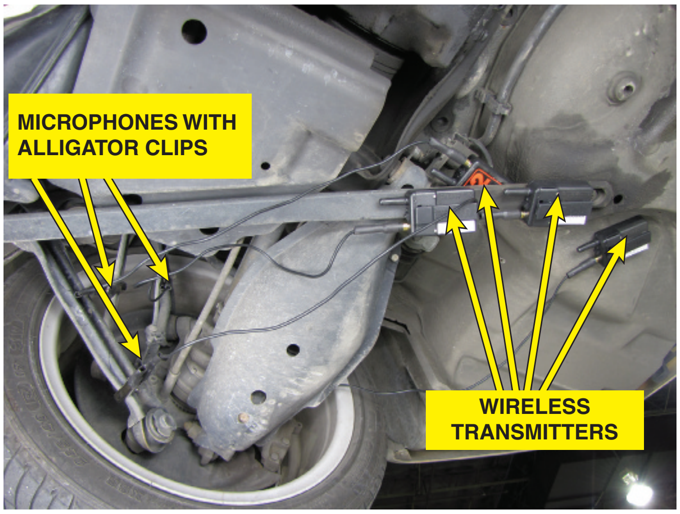

FIGURE 127–19 Chassis ear microphones attached to various suspension components using the integral clamps. The sound is transmitted wirelessly to the receiver inside the vehicle where an assistant technician can listen for noises while the vehicle is being driven.

TECH TIP

RAP It

Many technicians who service transmissions and drive axles frequently replace *all* bearings in the differential when there is a noise complaint. While this at first may seem to be overkill, these technicians have learned that one defective bearing may put particles in the lubricant, often causing the destruction of all the other bearings. This practice has been called *RAP* (replace all parts), and in the case of differentials, RAP may not be such a bad idea.

CASE STUDY

Engine Noise

An experienced technician was assigned to diagnose a loud engine noise. The noise sounded like a defective connecting rod bearing or other major engine problem. The alternator belt was found to be loose. Knowing that a loose belt can "whip" and cause noise, the belt was inspected and the belt tensioner was replaced but the noise was still heard. After stopping the engine, the technician found that the alternator belt was still loose. The problem was discovered to be a missing bolt that attached the alternator mounting bracket to the engine. The forces on the alternator caused the bracket to hit the engine. This noise was transmitted throughout the entire engine. Replacing the missing bracket bolt solved the loud engine noise and pleased a very relieved owner.

Summary:

Complaint—Owner complained of a loud engine noise.
Cause—The alternator bracket was loose, causing the noise due to a broken bracket bolt.
Correction—The alternator bracket bolt was replaced and the proper alternator belt tension was restored, and the noise was eliminated.

1. Describe how you can tell if the source of a vibration is at the front or the rear of a vehicle during a test-drive.
2. What are the steps to perform a neutral run-up test?
3. List two types of frequency-measuring instruments.
4. Discuss why the balance of a driveshaft on a rear-wheel-drive vehicle is more important than the balance of a front-wheel-drive axle shaft.
5. Explain how to check and balance a driveshaft on a rear-wheel-drive vehicle.

CHAPTER QUIZ

1. A vibration or noise can be caused by all of the following *except* ___________.
   a. exhaust system
   b. wheels and tires
   c. incorrect driveshaft angles
   d. exhaust smoke
2. An engine-related vibration can be best detected by performing a ___________.
   a. neutral run-up test
   b. test drive on a rough road
   c. hard acceleration from a stop
   d. Any of the above
3. Driveline vibrations due to a bent or out-of-balance driveshaft on a rear-wheel-drive vehicle usually produce a vibration that is___________.
   a. felt in the steering wheel
   b. seen as a vibrating dash or hood
   c. felt in the seat or all over the vehicle
   d. felt by the rear passengers only
4. A vibration is felt in the steering wheel during braking only. A common cause of the vibration is___________.
   a. worn idler arm
   b. out-of-balance front tires
   c. loose or defective wheel bearing(s)
   d. warped or nonparallel front disc brake rotors

5. The rolling circumference of both tires on the same axle of a four-wheel-drive vehicle should be within ___________.

a. 0.1 inch (2.5 mm)
b. 0.3 inch (7.6 mm)
c. 0.6 inch (15 mm)
d. 1.2 inch (30 mm)

6. Wheel/tire imbalance is the most common source of vibrations that occur in what frequency range?

a. 5–20 Hz
b. 20–50 Hz
c. 50–100 Hz
d. 100–150 Hz

7. The maximum allowable driveshaft runout is___________.

a. 0.030 inch (0.8 mm)
b. 0.10 inch (2.5 mm)
c. 0.50 inch (13 mm)
d. 0.015 inch (0.4 mm)

8. Measuring driveshaft U-joint phasing involves checking to see if the front and rear U-joints are ___________ with each other.

a. parallel
b. crossed
c. at an angle
d. opposite phased

9. A driveshaft can be checked for proper balance by marking the circumference of the shaft in four places and running the vehicle drive wheels to spot the point of imbalance using a(n) ___________.

a. reed tachometer
b. strobe light
c. electronic vibration analyzer
d. scan tool

10. A defective clutch release (throw-out) bearing is usually heard when the clutch is ___________.

a. engaged in neutral
b. disengaged in a gear
c. depressed to take up any freeplay
d. engaged in first gear or reverse

AUTOMATIC TRANSMISSION/ TRANSAXLE PRINCIPLES

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Explain the purpose, function, and operation of torque converters.
- Explain the purpose, function, and operation of lockup torque converters.
- Describe the various shift modes.
- Discuss planetary gear sets.
- Discuss compound planetary gear sets.
- Discuss automatic transaxles.
- Discuss nonplanetary gear automatic transaxles.

TORQUE CONVERTERS

PURPOSE AND FUNCTION The torque converter is located between the engine and the transmission/transaxle and performs the following functions:

1. Transmits and multiplies engine torque
2. Acts as a clutch between the engine and the transmission/transaxle
3. Allows slippage, which makes it possible for the transmission to be engaged in gear even when the vehicle and wheels are stopped.

PARTS The three major parts of the torque converter include

1. **Impeller.** The **impeller** is the driving member and rotates with the engine, and is located on the transmission side of the converter. The impeller inside the torque converter is also called the *pump* (not to be confused with the pressure pump).
2. **Turbine.** The **turbine** is located on the engine side of the converter. The impeller vanes pick up fluid in the converter housing and direct it toward the turbine. Fluid flow drives the turbine, and when the flow between the impeller and the turbine is adequate, the turbine rotates and turns the transmission input shaft.
3. **Stator.** A torque converter also contains the **stator**, or reactor, which is a reaction member mounted on a one-way clutch. ● **SEE FIGURE 128–1**.

The vanes used in each of the three elements of a torque converter are curved to increase the angle of the fluid flow. This also increases the force exerted by the fluid and improves the hydraulic advantage. The outlet side of the impeller vanes accelerates the fluid as it leaves the impeller to increase torque transfer to the turbine. The impeller and the turbine contain a curved shelf known as *split rings* to more efficiently move the fluid. ● **SEE FIGURE 128–2**.

OPERATION A torque converter acts like two fans pointing toward each other. Air pushed by the powered fan causes the

FIGURE 128–1 A torque converter is made from three parts: The impeller is located at the transmission end, attached to the housing, and is driven by the engine. The turbine is located at the engine side and is driven by the fluid flow from the impeller and drives the input shaft of the transmission. The stator redirects the flow to improve efficiency and multiply torque.

blades of the nonpowered fan to rotate. In the case of a torque converter, the two fans are the turbine and the impeller. The transmission fluid is the air that is being forced to turn the nonpowered fan. ● **SEE FIGURE 128–3**.

The fluid-only connection between the impeller and the turbine allows for absorption of sudden and harsh shocks in speed and/or torque. The curve of the stator vanes is opposite to the curve of the impeller and turbine vanes.

Since the stator is located between the impeller and turbine, it changes the direction of the fluid as it leaves the turbine, and thereby multiplies the torque from the impeller.

Torque converters are single-piece, welded and balanced assemblies that cannot be disassembled or easily repaired. Although they can be rebuilt using specialized equipment, most shops simply replace converters as a unit if they fail.

TORQUE CONVERTER FLEXPLATE The torque converter is typically bolted to a thin metal disc called a flexplate. The center of the flexplate often has a pilot indention for the nose of the converter, and the flexplate itself is bolted to the rear flange of the engine. ● **SEE FIGURE 128–4**.

The flexplate replaces the heavy flywheel used with a manual transmission. An important function of a flywheel is to smooth out engine pulsations and dampen vibrations. An automatic transmission does not require a conventional flywheel because the weight of the torque converter provides enough mass to dampen engine vibrations.

An external ring gear generally attaches to the outer rim of the flexplate, while on some applications the ring gear may be welded to the outside of the torque converter cover. This ring gear engages the starter motor pinion gear to turn the engine during starting. Some manufacturers also place the crankshaft position sensor tone ring in the outer lip of the flexplate.

NOTE: Hybrid vehicles may use a torque dampener plate in place of the torque converter. The dampener plate contains springs to absorb driveline shock, similar to a manual transmission clutch disc. It also drives the mechanical fluid pump and input shaft; however, it does not have transmission fluid, turbine, impeller, or stator elements inside it.

TORQUE CONVERTER DRIVES THE PUMP Oil pump drive shafts generally pass through the converter inside a hollow input or transfer shaft and internally connect to the converter housing by splines or a hexagon-shape shaft. The torque converter is also responsible for driving the transmission oil pump, sometimes called the *front pump,* because some early 1950s transmissions used a *rear pump* attached to the output shaft to allow "push starting" of automatic transmission-equipped vehicles. The inner portion of the front pump couples to the torque converter hub by using either "flats" or "tangs." The converter drive hub at the rear of the torque converter housing passes over the stator support and through the front oil seal to engage with and drive the oil pump. Because the shell of the torque converter is bolted to and rotates with the engine, this ensures that the fluid pump will only spin when the engine spins. ● **SEE FIGURE 128–5**.

One method is to attach the inner pump gear/rotor to the converter hub (most RWD transmissions); and the other is to use a separate oil pump drive shaft that connects the torque converter to the front oil pump (most FWD transaxles).

NOTE: Hybrid vehicles supplement the converter-driven pump with an electric-driven pump to ensure fluid flow and pressure even when the engine is stopped.

If one fan is operating, the blades of a second fan will be rotated by the flow of air past the fan that is unplugged, causing the blades to rotate.

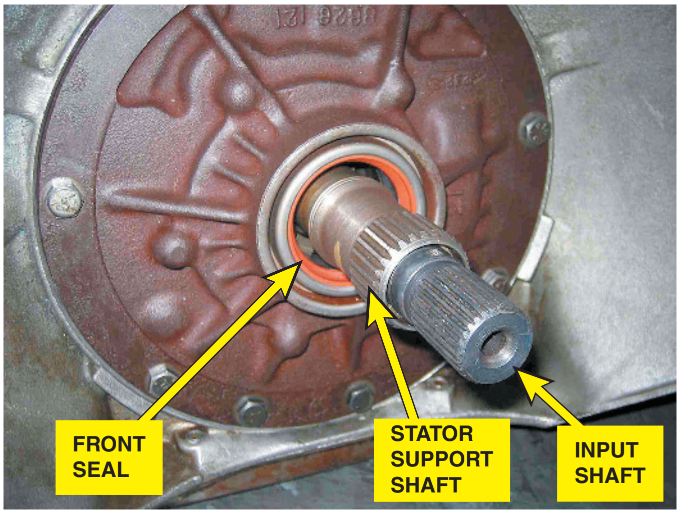

FIGURE 128–6 The internal splines inside the torque converter are connected to the splines on the stator support shaft and the turbine splines to the input shaft.

TRANSMISSION INPUT SHAFT Most rear-wheel-drive transmissions use an inline method to drive the converter and provide a direct mechanical connection between the turbine and the transmission input shaft. In a typical design, splines on the turbine connect it to the transmission input shaft and the stator hub mounts on a one-way overrunning clutch. The one-way clutch mounts on splines to a stationary extension of the oil pump called the *stator support,* or *reaction shaft.* ● **SEE FIGURE 128–6**.

TORQUE CONVERTER OPERATION Fluid sent to the torque converter from the transmission oil pump is picked up by the rotating vanes of the impeller and transferred to the turbine vanes. The two types of fluid flow inside a torque converter are rotary flow and vortex flow.

1. **Rotary flow** is created by the rotation of the torque converter and causes the oil (ATF) to flow around the circumference of the torque converter.
2. **Vortex flow** is the flow of the fluid from the impeller to the turbine and back to the impeller.

TORQUE MULTIPLICATION PHASE Torque multiplication in a torque converter occurs due to the following series of events inside the torque converter.

1. Fluid leaving the turbine vanes strikes the concave, or front side, of the stator vanes.
2. The stator vanes change the direction of the fluid so that it pushes the back side of the impeller vanes.
3. The stator redirects fluid flow because it remains stationary during the torque multiplication phase.
4. The stator hub mounts on a one-way clutch, freewheeling in a clockwise direction, but locking when driven in a counterclockwise direction.
5. The stator redirects fluid flow because it remains stationary during the torque multiplication phase.
6. When fluid from the turbine strikes the concave face of the stator vanes, it tries to drive the stator counterclockwise. By locking the stator, it can redirect the fluid back to the impeller.

TORQUE MULTIPLICATION, STATOR REVERSING OIL FLOW FROM TURBINE

FIGURE 128–7 Torque multiplication occurs when fluid leaving the turbine strikes the front of the stator vanes and is redirected back to the impeller.

7. The force of the fluid redirected from the stator adds to the force of the fluid flowing to the impeller, to increase the overall torque being transferred from the impeller to the turbine. This is called the *torque multiplication phase.* ● **SEE FIGURE 128–7**.

Torque multiplication occurs whenever the vortex flow makes a full cycle from impeller to turbine, through the stator and back to the impeller. A torque converter multiplies torque in relation to the speed ratio.

- At low speed ratios, the impeller (engine speed) is turning much faster than the turbine (transmission input shaft speed), so vortex flow is high and torque multiplication occurs.
- As turbine speed increases and approaches impeller speed, rotary flow increases, which reduces both vortex flow and torque multiplication.
- As the speed ratio approaches 90%, torque multiplication becomes minimal and a torque converter functions like a fluid coupling.

The stator hub mounts on a one-way clutch, freewheeling in a clockwise direction, but locking when driven in a counterclockwise direction. When fluid from the turbine strikes the concave face of the stator vanes, it tries to drive the stator counterclockwise. By locking the stator, it can redirect the fluid back to the impeller. ● **SEE FIGURE 128–8**.

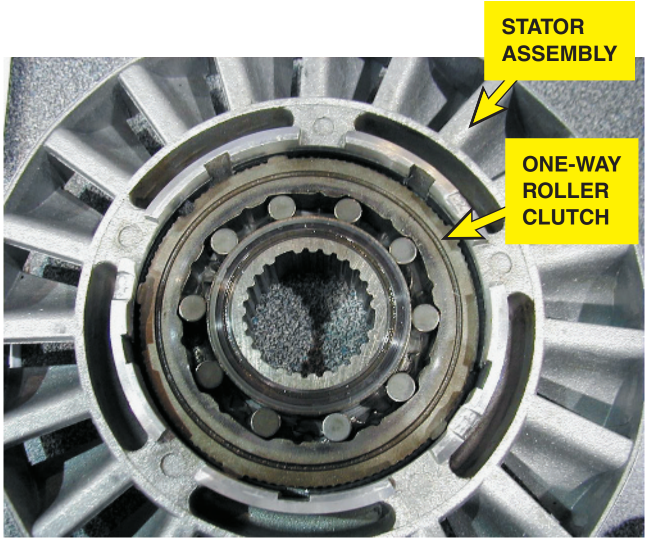

FIGURE 128–8 A stator contains a one-way roller clutch that locks it from rotating in one direction and allows it to rotate freely in the opposite direction.

COUPLING PHASE When the speed ratio is 90° or more, fluid flow in the torque converter is mostly rotary flow and the angle of flow from turbine to stator increases. This is called the **coupling phase**. When the torque converter reaches this phase, the turbine is traveling at nearly the same speed as the impeller, rotary flow is much greater than vortex flow, and the torque multiplication drops. During this phase, fluid from the turbine strikes the convex side, or backside, of the stator vanes rather than the concave side. As the force of fluid striking the backside becomes great enough to drive the stator clockwise, the stator one-way clutch overruns. With the clutch overrunning the turbine, impeller, and stator, all rotate in the same direction and at approximately the same speed. The stator unlocks and freewheels once the angle of fluid flow changes enough to strike the opposite side of the stator vanes and rotate the stator clockwise.

Torque multiplication drops as the torque converter approaches the coupling phase because the stator no longer redirects fluid to increase the flow from impeller to turbine. When the torque converter reaches coupling speed, the turbine is traveling at nearly the same speed as the impeller, rotary flow is much greater than vortex flow, and the torque converter simply transmits torque like a fluid coupling. During the coupling phase, most converters lose about 10% coupling efficiency, which means that there is a 10% speed difference between the impeller and turbine.

STALL SPEED **Stall speed** is the engine speed when the engine drives the impeller at the maximum speed possible without moving the turbine. The engine speed at which this occurs is called the torque converter stall speed. When the impeller rotates but the turbine does not, the speed ratio is zero. This is the lowest possible speed ratio and the greatest possible torque multiplication. Most modern torque converters multiply torque in the range of 2:1 to 2.5:1 at the stall speed. Typical stall speeds are designed to match the needs of individual vehicles and engines and range from a low of about 1450 RPM to as high in some stock vehicles as 2500 RPM or even higher for high-performance torque converters.

NORMAL OPERATION When the transmission selector is moved from park (P) or neutral (N) into a drive gear, some engine torque is transferred to the input shaft of the transmission or transaxle. The vehicle will move slightly if the brakes are released. This slight movement of the vehicle when the engine is at idle speed and the brakes are released is called **creep**. Therefore, a slight movement is normal for a vehicle equipped with an automatic transmission.

NOTE: Vehicle creep is more noticeable when the engine is cold due to the higher idle speed.

TORQUE CONVERTER DIAMETER The outside diameter of a torque converter and the angle of its stator blades determine the stall speed of the converter. When both a small and large diameter converter share the same stator blade angle and turn at the same speed, the smaller converter creates less centrifugal force to move the fluid inside. As a result, the small diameter converter has a higher stall speed, multiplies torque at higher engine speeds, and will not couple until the engine reaches high speeds. In comparison, the large diameter converter has a lower stall speed, multiplies torque at lower engine speeds, and also couples at a lower engine speed.

Vehicle manufacturers select torque converters to match the powertrain requirements and operating demands of each vehicle application.

- A vehicle with a large engine that produces a lot of torque at low RPM will often use a torque converter that couples at low speeds for greater fuel economy and lowest possible exhaust emissions.
- Vehicles with smaller engines that produce less torque at low RPM will use a torque converter that allows the engine to operate higher in its torque curve, where more power is available. High-performance vehicles with automatic transmissions use small diameter converters for the same reason.
- Therefore, the vehicle manufacturer selects the best stall speed based on the power band of the engine and the weight of the vehicle.

LOCKUP TORQUE CONVERTER

PURPOSE AND FUNCTION Even the most efficient torque converters slip 8% to 12% during operation because the fluid that transmits torque exhibits a type of slippage known as fluid shear. Fluid shear creates friction heat, but performs no work when the different layers of fluid slide past each other.

Eliminating torque converter slippage can improve fuel economy by approximately 4% to 5% during freeway cruising. With the increased emphasis on fuel economy and low exhaust emissions for late model vehicles, this became an important goal for automotive engineers. An additional benefit to reducing slippage is a reduction of transmission operating temperature, which increases transmission life expectancy. Lockup torque converters reduce slippage by using a **torque converter clutch (TCC)** to lock the impeller to the cover (shell). Similar to a clutch for a manual transmission, a TCC uses a friction disc operated by a hydraulic piston to mechanically couple the turbine to the converter (cover/shell). Engaging the clutch creates mechanical connection between the engine and transmission, resulting in a direct 1:1 drive ratio without slippage. ● **SEE FIGURE 128–9**.

CONVERTER CLUTCH CONTROL The first hydraulic lockup converters were controlled entirely by hydraulic pressure and spool valves in the transmission valve body. Some older designs added simple electric switches and solenoids to control pressure to the converter clutch. Since the early 1990s, the powertrain control module (PCM) or the transmission control module (TCM) regulates the timing and application of the clutch. The torque converter clutch operates under the following conditions:

- Lockup may also be limited to specific vehicle speeds or operating conditions. For most vehicles, lockup can occur at speeds over 25 to 30 MPH (40 to 48 km/h) but can occur sooner in many newer transmissions/transaxles.
- Once lockup occurs, the clutch may disengage automatically during certain operating conditions such as part- or full-throttle downshift. At these times, the increased acceleration requirements generally override the need for better fuel economy.
- Most computer systems can lock and unlock or modulate a converter clutch hundreds of times per minute to meet the vehicle demands of the moment and some recent systems also allow partial lockup of the torque converter. Traditional lockup torque converters operate either locked or unlocked. Partial lockup converters allow a regulated amount of slippage at the clutch. Each type of torque converter requires a certain type of friction material. ● **SEE FIGURE 128–10**.
- This allows the converter to lock up smoothly, improving fuel economy and performance, without the drawback of shock to the driveline. Using the wrong type of automatic transmission fluid (ATF) can alter the frictional properties

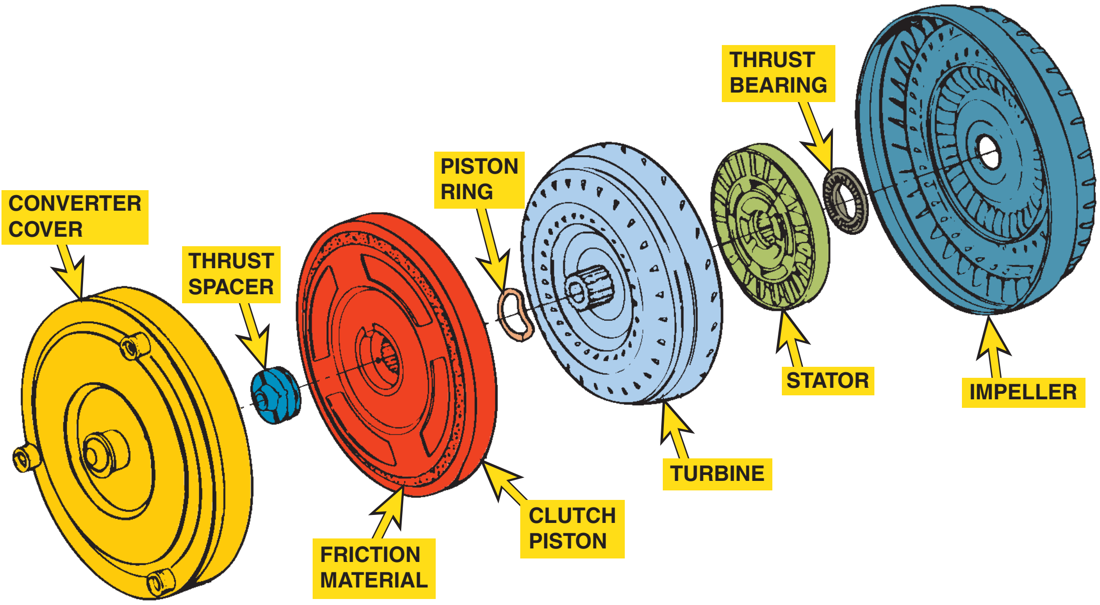

FIGURE 128–9 An expanded view of a typical torque converter assembly showing the torque converter clutch (TCC).

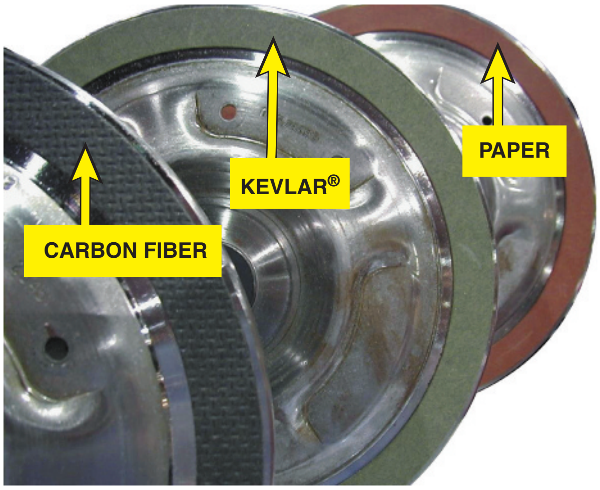

FIGURE 128–10 Torque converter clutch friction material is determined by the vehicle manufacturer to provide the needed coefficient of friction needed. For example, many older units use a paper-type friction material because they are fully applied or released, whereas most newer units use a synthetic material such as Kevlar® or carbon fiber because the torque converter clutch is pulsed on and off, therefore requiring a more robust material for long service life.

of the lockup clutch, leading to shudder or other similar customer complaints.

- Most lockup converters automatically disengage the torque converter clutch each time the brake pedal is depressed by the driver or if the accelerator pedal is released for more than a couple of seconds, which is necessary for vehicle deceleration without stalling the engine. ● **SEE FIGURE 128–11**.

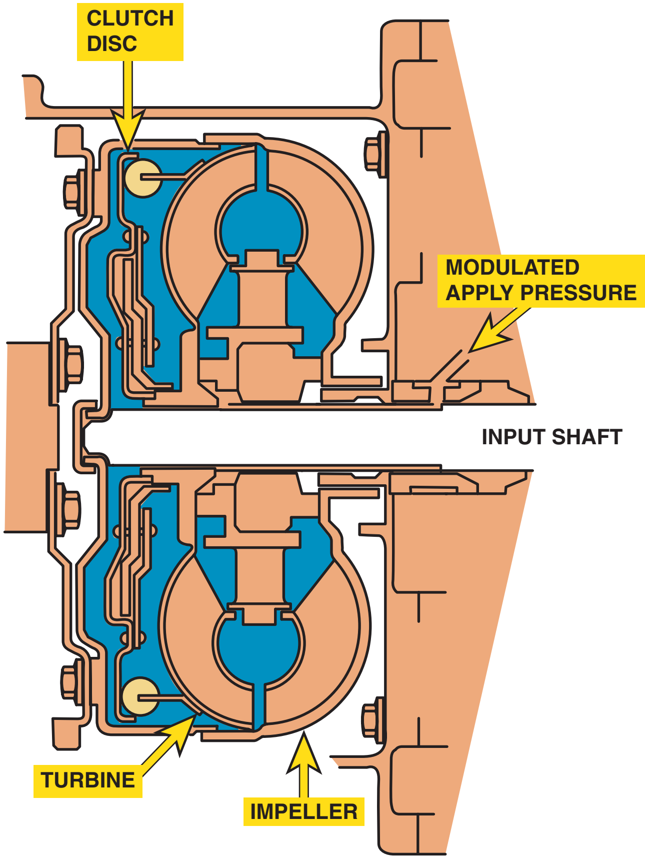

FIGURE 128–11 A cross-sectional view of a pulse-width-modulated (PWM) torque converter clutch. The powertrain control module (PCM) pulses the control solenoid, which then controls the fluid flow to apply the torque converter clutch.

TECH TIP

Use a Smaller Diameter Torque Converter for Improved Performance

A smaller-than-stock-diameter torque converter will not be capable of absorbing as much torque as a larger (stock) torque converter. As a result, the stall speed is increased. Because an engine develops more torque with increased speed (up to a point), the smaller torque converter will allow the engine to increase to a higher speed and create more torque to the transmission than would be capable with the stock torque converter.

This is especially helpful for modified engines because an engine having a camshaft with increased lift and duration usually lacks low RPM torque. By using a smaller torque converter, the stall speed is increased to better match the engine torque.

CAUTION: Using a torque converter with a different stall speed rating is likely to increase exhaust emissions and decrease fuel economy as well as void the warranty on the vehicle.

SHIFT MODES

Most automatic transmissions and transaxles include the following shift modes. ● **SEE FIGURE 128–12**.

- **Park.** In the park position, the output shaft is locked to the case of the transmission/transaxle, which keeps the vehicle from moving. No power is transmitted through the unit so the engine can remain running while the vehicle is held stationary. In the park position:
  1. The engine can be started by the driver.
  2. To move the shifter out of the park position on a late model vehicle, the brake pedal must be depressed to release the brake transmission shift interlock.
- **Reverse.** The reverse gear selector position is used to move the vehicle in reverse. Reverse usually uses a lower gear ratio than any of the forward gears.

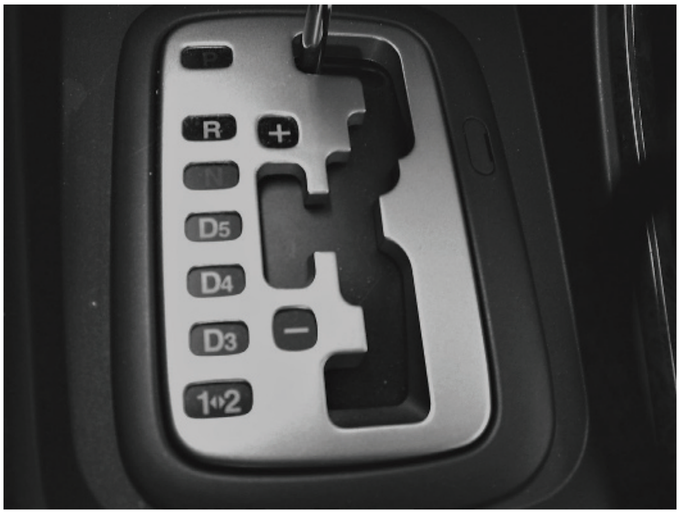

FIGURE 128–12 The gear selector is often called the "PRNDL," pronounced "prindle," regardless of the actual letters or numbers used.

- **Neutral.** In the neutral position, no torque is being transmitted through the automatic transmission/transaxle. In this position, the engine can be started by the driver.
- **Overdrive (OD).** The OD is the normal position for the shift selector for most driving conditions. This position allows the transmission or transaxle to shift through all forward gears as needed for the best fuel economy and lowest exhaust emissions.
- **Drive (D).** The D position includes the overdrive ratios in most vehicles. If there is an overdrive shift mode, however, then D is used to provide all forward gears except overdrive. Use this position when driving in hilly areas or when towing in the vehicle equipped with an overdrive selection.
- **Third (3).** In third position, the transmission/transaxle will upshift normally to third gear but will not upshift to a higher gear. When the third (3) position is selected while driving in a higher gear, the transmission will downshift into third if the vehicle speed is low enough to prevent the engine from being overrevved. This gear selection is used for the gentle grades at a moderate vehicle speed.
- **Second (2).** The second position is used for slowing the vehicle while descending long grades. In this gear selection, the vehicle speed is controlled and the engine speed is increased to provide engine compression braking. This gear selection is used for the gentle grades at a moderate vehicle speed.
- **First (1 or Low).** The first (or low) position is used for slowing the vehicle while descending long grades. In this gear selection, the vehicle speed is controlled and the engine speed is increased to provide engine compression breaking. This gear selection is used for the steepest grades at the lowest possible speed.

PLANETARY GEAR SETS

PURPOSE AND FUNCTION In a manual transmission, different gear ratios are obtained by sliding the gears into mesh. However, torque flow must be momentarily interrupted (accomplished by using a clutch) before the gears are shifted. With an automatic transmission there is no driver-operated clutch, so gear shifts are not made by sliding gears into mesh. Most automatic transmissions use a planetary gear set system that does not require manual gear shifting or an interruption of torque flow to change gear ratios.

PARTS AND OPERATION A simple planetary gear set consists of three primary components:

- Sun gear
- Planet carrier (including planet pinion gears)
- Ring (annulus) gear

As discussed in the last chapter on transfer cases, the **sun gear** gets its name from its position at the center of the gear set. The **planet carrier** holds the pinion gears, also known as planet gears, which revolve around the sun gear. The planet carrier assembly is commonly referred to simply as "the carrier."

The outermost member of the gear set is the **ring gear**, the internal type with teeth inside. The ring gear is sometimes called an annulus or internal gear. The pinion gears are in simultaneous mesh with both the sun gear and the ring gear. ● **SEE FIGURE 128–13**.

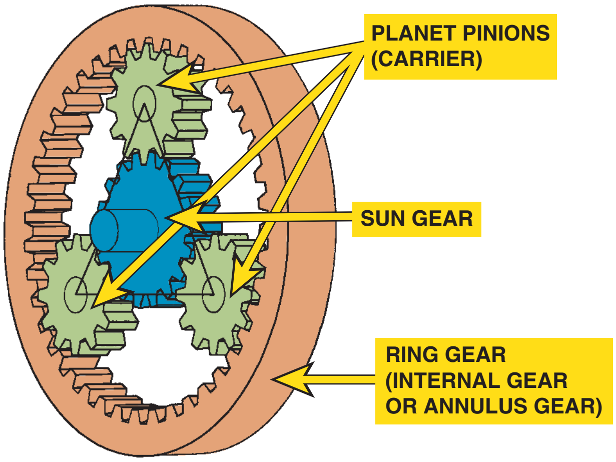

FIGURE 128–13 A typical planetary gear set showing the terms that are used to describe each member.

The pinion gears are free to rotate on pins that are part of the carrier, and the entire assembly rotates to direct torque flow. Most transmission gear sets use three, four, or even five planet pinions.

The pinions are fully meshed with both the sun gear and internal ring gear at all times. The planetary gears never disengage to change gear ratios; torque is simply redirected. The torque flow through a planetary gear set, both input and output, occurs along a single axis.

PLANETARY GEAR SET TORQUE FLOW In a planetary gear set, the following is done to achieve the various gear ratios and reverse.

- One of the members is being driven (input).
- One of the members is being held (reaction member).
- One of the members is the output.

Therefore, driving one gear will cause all of the other gears to rotate as well. This allows the gear set to provide different gear ratios, depending upon how torque is distributed through the assembly. To transmit torque through a planetary gear set, a drive member rotates while a second member is held, which causes a third member to be driven. ● **SEE FIGURE 128–14**.

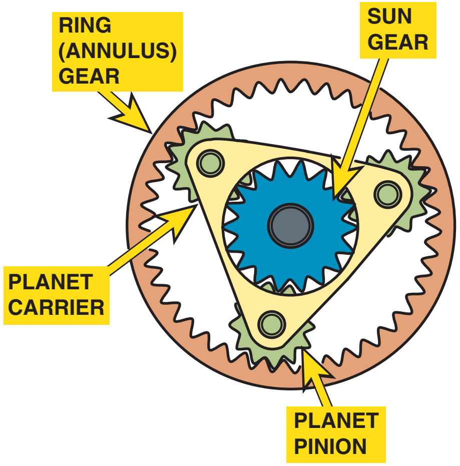

FIGURE 128–14 A typical planetary gear set showing the planet carrier, which supports all of the pinion gears (also called planet pinion gears).

Each member of a planetary gear set can play any one of these three roles to transmit torque. The various combinations of drive, held, and driven members result in the number of gear ratios available and change the direction of rotation as well for reverse.

NOTE: The held member can also be allowed to move one direction or another as it is being held and does not necessarily need to be held to zero RPM to create a variable gear ratio. This is done in hybrid electric vehicle transmissions.

Torque flows through a planetary gear set in several steps to get from the drive action of the first member to the driven action of the last member.

- The terms "drive" and "driven" simply describe how any two gears work together.
- When three or more gears are involved, the second gear is a *driven* gear in relation to the first, but it becomes a *drive* gear in relation to the third gear.
- For this reason, the drive member of a planetary gear set is known as the **input member**, the held member is the **reaction member**, and the driven member is the **output member**.

SIMPLE PLANETARY GEAR SET SYSTEMS A simple planetary gear set system consists of one sun gear, the carrier, and a ring gear. A single planetary gear set can provide all of the necessary gear ratios for a basic automatic transmission. ● **SEE FIGURES 128–15 THROUGH 128–17.**

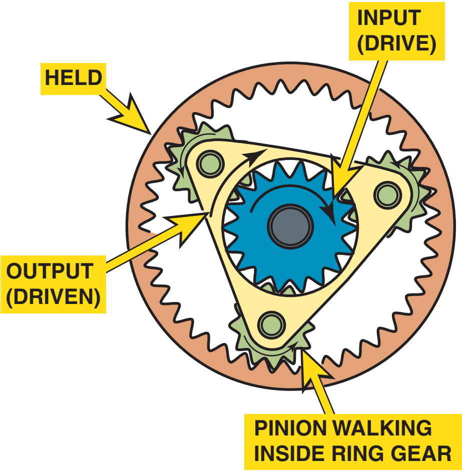

FIGURE 128–15 Maximum reduction can be achieved by using the sun gear as the input, holding the ring gear and using the planet carrier as the output.

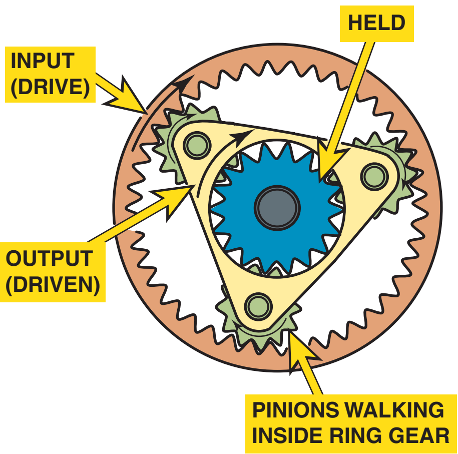

FIGURE 128–16 Minimum reduction can be achieved by using the ring gear as the input, holding the sun gear and using the planet carrier as the output.

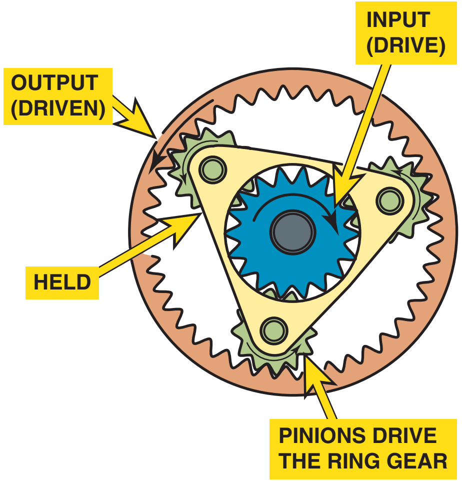

FIGURE 128–17 Reverse can be achieved by using the sun gear as the input, holding the planet carrier and using the ring gear as the output.

A simple planetary gear set is often used together with a compound planetary gear set to provide additional gear ratios. ● **SEE CHART 128–1** for the six possible gear ratios and how they are achieved.

SUN GEAR	PLANET CARRIER	RING GEAR	SPEED	TORQUE	DIRECTION
Input (Drive)	Output (Driven)	Held	Maximum reduction	Increase	Same as Input
Output (Driven)	Input (Drive)	Held	Maximum increase	Reduction	Same as Input
Held	Output (Driven)	Input (Drive)	Minimum reduction	Increase	Same as Input

Input (Drive)	Held	Output (Driven)	Reduction	Increase	Reverse of Input
Output (Driven)	Held	Input (Drive)	Increase	Reduction	Reverse of Input

CHART 128–1

If any two members are locked together, then the resulting output is 1:1 ratio in the same direction as the input (direct drive). If no member is held (locked), then there is no output (neutral).

COMPOUND PLANETARY GEAR SET

A *compound planetary gear set* system is a configuration that contains more than just the three basic members of a simple planetary system. A compound planetary gear set is one or more simple planetary gears sets with one or more common gears. Compound planetary gear sets are capable of providing various combinations of gear reduction, direct drive, neutral, reverse, and overdrive.

SIMPSON GEAR SET One of the most popular compound planetary designs is the **Simpson gear set**. Named for its inventor, Howard Woodworth Simpson (1892–1963), an American automotive engineer, the Simpson gear set consists of two simple planetary gear sets that share a common sun gear. ● **SEE FIGURE 128–18**.

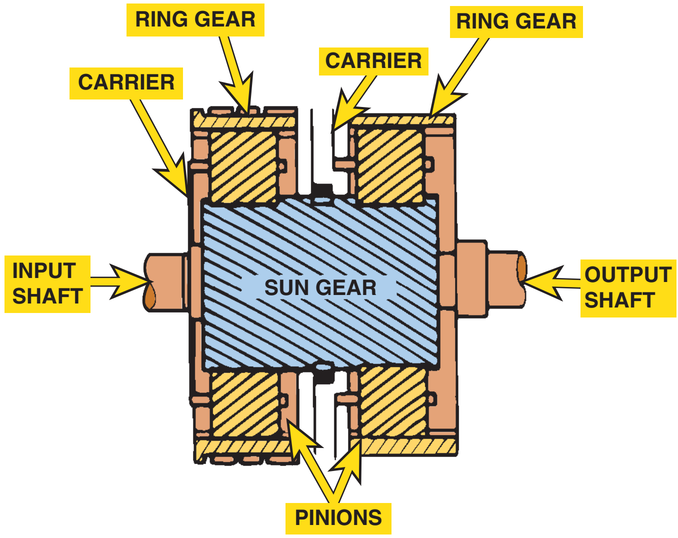

FIGURE 128–18 A Simpson planet gear set is composed of two ring gears and two planet carrier assemblies that share one sun gear.

FREQUENTLY ASKED QUESTION

What Companies Build Automatic Transmissions?

Many larger automobile manufacturers make their own automatic transmissions, including General Motors, Ford, Chrysler, and Honda. However, several companies manufacture automatic transmissions and transaxles that are used in a variety of vehicles. These include

- **ZF Friedrichshafen AG.** This German company manufactures manual and automatic transmissions and transaxles for many vehicle manufacturers, including Mercedes, BMW, Volvo, VW, Audi, Jaguar, Chrysler, Bentley, and Maserati.
- **Aisin AW.** This Japanese company makes automatic transmissions for many vehicle manufacturers, including Ford, Toyota, Nissan, Mazda, Mitsubishi, Subaru, Kia, and VW.
- **JATCO (Japan Automatic Transmission Company).** This is a Japanese manufacturer of automatic transmissions and transaxles for many vehicle manufacturers, including Nissan, Mazda, Infinity, VW, Mitsubishi, and Suzuki.

FREQUENTLY ASKED QUESTION

What Do All the Letters and Numbers Mean in Transmission Designations?

The numbers and letters usually mean the following:

- **Number of forward speeds.** The number of forward speeds may include four, five, or six (such as GM 4T60-E four speed unit).
- **Front-wheel drive or rear-wheel drive.** The letter **T** usually means *transverse* (front-wheel-drive transaxle) such as the Chrysler 41-TE; the **L** means *longitudinal* (rear-wheel-drive transmission) such as the General Motors 6L80; and the **R** means *rear-wheel drive* such as the Ford 5R55E.
- **Electronically controlled.** The letter **E** is often used to indicate that the unit is electronically controlled, and **M** or **H** is used to designate older mechanically (hydraulically) controlled units. All automatic transmissions built since the early 1990s are electronically controlled; therefore, **E** is often included in the designation of newer designs of transmission or transaxles.
- **Torque rating.** The torque rating is usually designated by a number where the higher the number, the higher the amount of torque that the unit is designed to handle. In a GM 6L80-E. the torque rating is 80.

Always check service information for the exact transmission designation for the vehicle being studied or serviced.

This combination is capable of providing three forward gears, as well as neutral and reverse. Basic operation, construction, and methods of obtaining various gear ratios with a simple planetary gear set also apply to the Simpson gear set. The main difference is the number of gear ratios that are available using more than one planetary gear set.

RAVIGNEAUX GEAR SET Another popular compound planetary design is the **Ravigneaux gear set**. The Ravigneaux system has the following:

- Two sun gears
- Two planet pinion sets, one longer than the other, supported in one carrier
- A single ring gear

● **SEE FIGURE 128–19**.

This design provides four forward gears (two in reduction, one direct, and one overdrive) as well as neutral and reverse. Basic planetary gear set operation, construction, and control methods also apply to the Ravigneaux gear set. An overdrive ratio means the following:

- The output shaft is rotating faster (higher RPM) than the engine crankshaft.
- The ratio is always expressed to the relative ratio of the input shaft speed so that all overdrive ratios are less than 1. For example, 0.75:1 is an overdrive ratio meaning the output is rotating 25 percent faster than the input shaft speed.

retired engineer who devised a unique way to create a simple and efficient six-speed automatic transmission gear set. It was first produced by ZF in 2002. The Lapelletier gear set is constructed by connecting a planetary gear set in front of a Ravigneaux gear set. Besides ZF, General Motors uses the Lapelletier gear set in the 6L45, 6L50, and 6L90 rear-wheel-drive transmissions, and Ford uses it in the 6R60, 6R75, and 6R80 transmissions.

AUTOMATIC TRANSAXLES

TERMINOLOGY Automatic transaxles include a differential assembly as well as the planetary gear sets of an automatic transmission. The engine torque also needs to be transferred by the use of a chain or gears to provide a shorter overall length so it can be used with an engine mounted transversely in the engine compartment. Some use gears and others use a chain to transfer engine torque to either the planetary gear sets or to the differential (final drive) assembly. ● **SEE FIGURES 128–20 AND 128–21**.

A transaxle can be used in the following applications:

- Front engine, front-wheel drive
- Rear engine, rear-wheel drive
- Front engine, all-wheel drive
- Mid engine, rear-wheel drive

FINAL DRIVE UNITS A transaxle includes a differential assembly, often called a *final drive* assembly as part of the transaxle. This final drive assembly connects the output from the gear sets to the drive axle shafts. The final drive assembly includes the side gears and pinions gears as well as the housing. ● **SEE FIGURE 128–22**.

NONPLANETARY GEAR AUTOMATIC TRANSAXLES

Honda and Saturn vehicles use an automatic transmission with no planetary gear sets. This type is similar to and uses many of the same parts as their manual transaxles. This design uses hydraulic clutches instead of synchronizers to make the shift between gears. By using the same parts as manual transaxles, this automatic transaxle has the following advantages:

1. It allows both manual and automatic transmissions to be manufactured in the same plant, therefore reducing cost.
2. By using many of the same parts for both manual and automatic transaxles, manufacturers see a cost reduction.
3. Honda automatic transaxles are diagnosed, and if an internal fault is detected, the entire assembly is replaced with a remanufactured unit. Honda dealership technicians do not repair automatic transaxles. ● **SEE FIGURE 128–23**.

CONTINUOUSLY VARIABLE AND DUAL-CLUTCH AUTOMATIC TRANSMISSIONS

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Describe the function, advantages, and disadvantages of a continuously variable transmission.
- Describe the construction of a continuously variable transmission.
- Discuss the electronic controls of a CVT.
- Discuss the operation of a CVT.
- Explain CVT pressure testing.
- Discuss CVT fluid.
- Discuss CVT-related DTCs.
- Discuss the parts and operation of a dual-clutch automatic transmission.
- Discuss the dual-clutch transaxle.
- Describe the diagnostic and service procedures for a dual clutch transmission/transaxle system.

CONTINUOUSLY VARIABLE TRANSMISSION (CVT)

PURPOSE AND FUNCTION A **continuously variable transmission (CVT)** is usually found on some front-wheel-drive vehicles that use a transaxle. A CVT varies the gear ratio in a continuous manner instead of in a series of steps or fixed gear ratios. The power flow is through a steel belt between two pulleys that change their width and effective diameter. When the vehicle accelerates from a standing start, the driving pulley is small and the driven pulley is large. This gives a gear reduction identical to a small gear driving a large gear, which provides an increase in torque and a decrease in speed. CVTs are more efficient than either manual or automatic transmissions while still providing the driving ease of an automatic transmission. ● **SEE FIGURE 129–1**.

ADVANTAGES A CVT offers the following advantages over a planetary-gear automatic transmission:

- Compact, very short
- Lighter weight
- Constant, stepless acceleration with engine staying at the RPM for maximum power
- Efficient fuel use and emissions, cruise with engine staying at the RPM for maximum efficiency
- Lower internal power loss

One method used to compare transmissions is the engine revolutions for a specific driving cycle. A test vehicle using a 3.0-L engine and a CVT showed 3% fewer revolutions than the same vehicle with a five-speed transmission and 11% less than with a four-speed transmission. This should equal a gain of about 12% in fuel economy. These transmissions are used by Audi, Dodge, Ford, Honda, Subaru, Toyota, and Nissan.

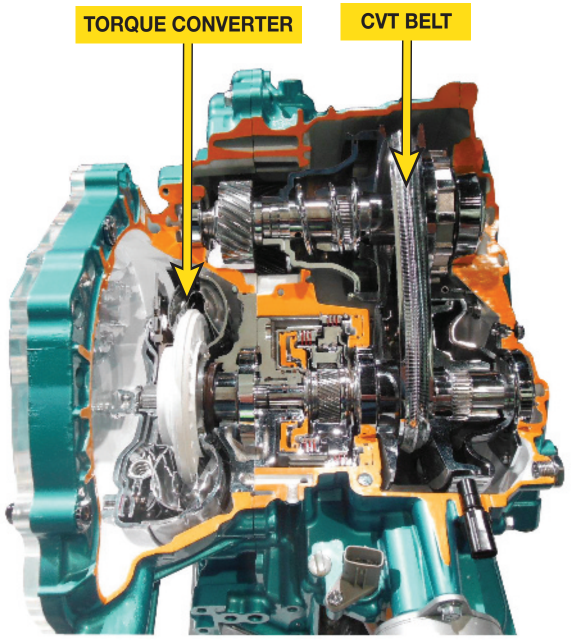

FIGURE 129–1 A typical CVT transaxle cutaway showing the torque converter and CVT belt.

DISADVANTAGES The disadvantages of a CVT compared to conventional automatic transmission include

- High and constant engine speed when accelerating rapidly.
- Requires special fluid that may not be readily available.
- Often not repaired but instead replaced as an assembly if the unit fails.

CONTINUOUSLY VARIABLE GEAR RATIOS As the speed increases, the diameter of the driving pulley increases as the sides of the pulley move together. While this happens, the driven pulley is made wider, and therefore, smaller in diameter. At cruising speeds, the driving pulley is larger than the driven pulley, which produces an overdrive ratio.

The pulleys change size smoothly and evenly, which produces a somewhat odd sensation when the vehicle accelerates from a stop. When the throttle is depressed, the engine speed increases to the point of good torque output and the gear ratio selected by the CVT causes the engine to stay at this RPM while the vehicle accelerates. The pulleys move to higher ratios as vehicle speed increases. This is a different sensation than the familiar engine speed increase in each gear and the engine speed decrease after an upshift. ● **SEE FIGURES 129–2 AND 129–3**.

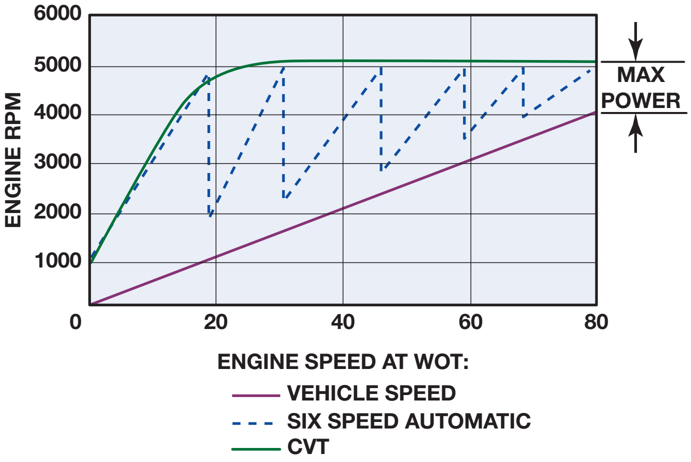

FIGURE 129–3 Engine speed and vehicle speed of a CVT transaxle compared to a typical six-speed conventional automatic transaxle.

CONSTRUCTION

TERMINOLOGY Instead of using three or more gears, a continuously variable transmission uses two variable-width pulleys, sometimes called **variators**, to change the gear ratio.

OPERATION The pulleys used in CVT design can vary their width by varying the hydraulic pressure applied to them. Each pulley has a movable face and a fixed face.

- The movable face for each pulley is attached to a piston that has hydraulic control pressure applied to it.
- Higher application pressure on the movable face causes the pulley to become narrow and this makes the steel belt ride closer to the outside diameter of the pulley. A lower application pressure will allow the pulley to become wider and the belt will ride closer to the pulley axis.

FREQUENTLY ASKED QUESTION

What Is It Like to Drive a Vehicle Equipped with CVT?

For most people, driving a vehicle equipped with a continuously variable transmission (CVT) is the same as driving the vehicle equipped with a conventional automatic transmission/transaxle. The vehicle creeps slightly when the brake is released and accelerates normally when the throttle is opened. Because no shifts occur, the first thing the driver and passenger notice is that it is very smooth. If the vehicle is equipped with a tachometer, the driver may notice that the engine speed increases when first accelerating and often remains higher until the vehicle speed increases. During periods of rapid acceleration, the engine speed may be close to its maximum and thereby creates noise and vibration often not experienced in a similar vehicle. Because the vehicle speed slowly catches up to the engine speed, this effect is often referred to as the "**rubber band effect**" and is most noticeable only during periods of rapid acceleration. However, the fuel economy improvement of a CVT compared to a conventional automatic transmission makes the slight difference a reasonable trade-off.

If a low hydraulic pressure is applied to the drive pulley and a high hydraulic pressure is applied to the driven pulley, a low speed ratio is achieved.

A CVT has an infinite number of gear ratios between its lowest ratio (about 3.7:1) and highest ratio, which is a 0.27:1 overdrive.

A CVT improves efficiency by changing ratios from underdrive/reduction to overdrive in a gradual, continuous manner. The primary/drive pulley is attached to the input shaft. The secondary/driven pulley is on the output shaft and drives the final drive gears. Each pulley, also called a *sheave*, has two sides:

1. One is fixed so it cannot move.
2. The other can float sideways to change pulley width.

When the vehicle is at rest, the primary pulley is wide so the belt sits low on the pulley, and the secondary pulley is narrow so the belt sits high. This produces the lowest underdrive ratio. ● **SEE FIGURE 129–4**.

The secondary pulley is spring loaded to force it to a narrow position. The primary pulley is adjusted to control the gear ratio, and the secondary pulley is adjusted to maintain tension on the belt. The belt must never be loose between the pulleys.

- At start, the pulley halves/discs on the input (primary) shaft are spread apart, and the pair of pulley halves on the output (secondary) shaft are pushed together. This produces a small pulley driving a large pulley, which produces the lowest drive ratio.
- As the vehicle moves, the floating side of the primary pulley moves inward, making the pulley narrower and forcing the belt to move out to a wider diameter. This produces a higher gear ratio.
- Both pulleys must maintain enough pressure on the drive belt to transfer the required torque. Fluid pressure is used to force the drive piston/pulley to a narrower position and the driven pulley to a wider position. The secondary pulley is spring loaded to force it to a narrow position. The primary pulley is adjusted to control the gear ratio, and the secondary pulley is adjusted to maintain tension on the belt. The belt must never be loose between the pulleys.

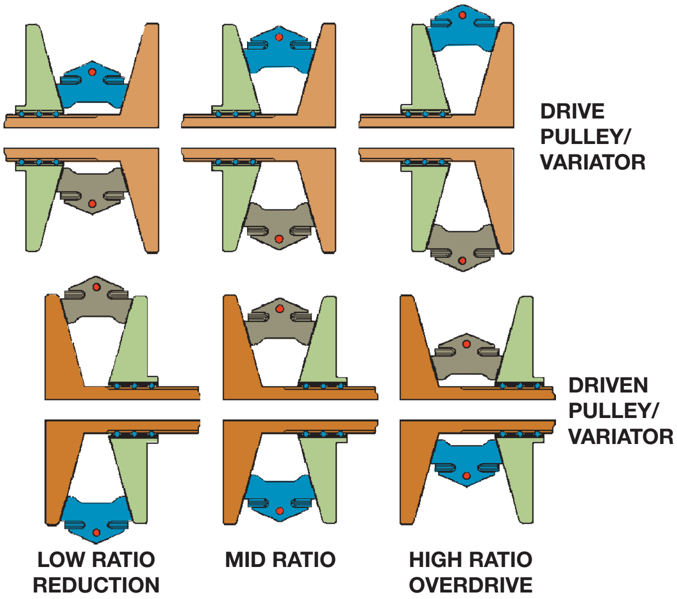

FIGURE 129–4 The drive pulley is wide while the driven pulley is narrow for a low ratio vehicle start (left). The ratio changes by making the drive pulley narrow and the driven pulley wider.

A reverse gear set, controlled by a multi-plate clutch pack, is used to produce reverse.

DRIVE BELT Two different styles of fixed-length steel belts are used.

1. **Push belt** It is made up of about 400 wedge-shaped segments that are held together by two steel bands. Each band is made of multiple layers to allow flexibility. The segment sides contact the pulley sides. A push belt is often called the *Van Doorne design*. This style of belt is directional, and is usually marked with an arrow to show belt direction. ● **SEE FIGURE 129–5**.
2. **Pull chain** It is made up of links and link pins, much like a silent chain. The ends of the link pins contact the pulley sides. This style is also called a *Luk chain drive*. ● **SEE FIGURE 129–6**.

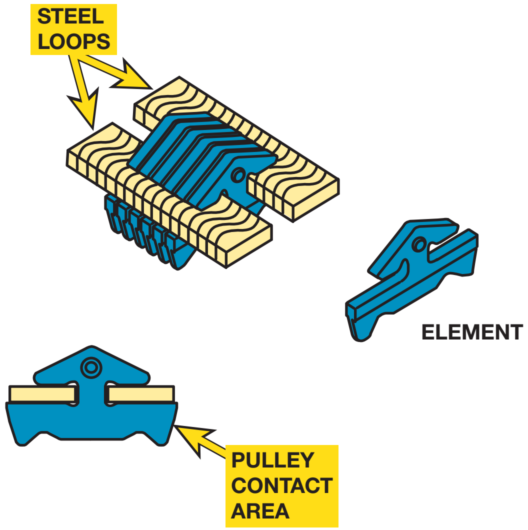

FIGURE 129–5 A Typical push-type CVT belt construction.

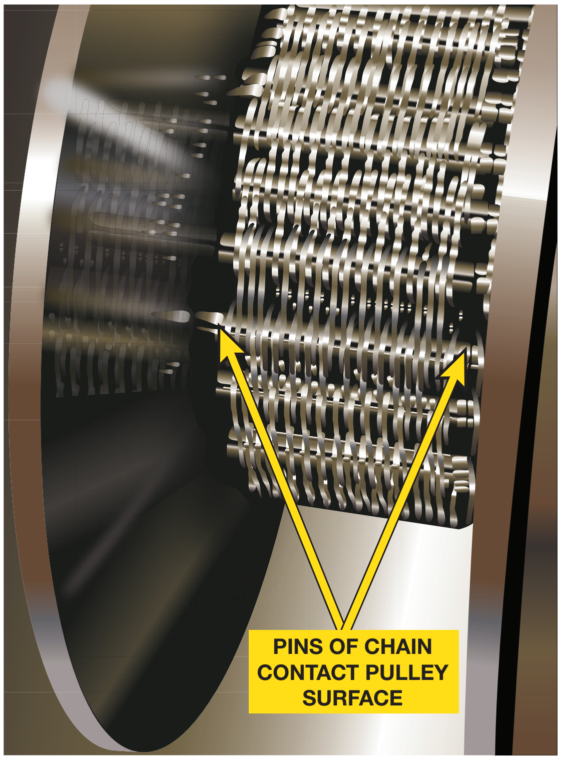

FIGURE 129–6 The pull chain looks similar to a silent chain.

CVT ELECTRONIC CONTROLS

The transmission control module (TCM) of a CVT uses direct and indirect inputs to monitor transmission and engine operation. ● **SEE FIGURE 129–7**.

INPUTS Direct inputs are as follows:

- **Transmission range sensor (TRS)**. A multi-contact switch operated by the manual shift lever.
- **Input speed sensor (ISS)**. Can be a magnetic or a Hall-effect sensor.
- **Output speed sensor (OSS)**. Can be a magnetic or a Hall-effect sensor.
- **Primary pressure sensor (PPS)**. A pressure transducer to monitor primary pulley pressure. The pressure measured is called the **primary oil pressure (POP)**.
- **Secondary pressure sensor (SPS)**. A pressure transducer to monitor secondary pulley pressure. The pressure measured is called the **secondary oil pressure (SOP)**.
- **Transmission temperature sensor (TTS)**. A negative temperature coefficient (NTC) thermistor used to measure the temperature of the transaxle.

INPUTS FROM CAN BUS Indirect inputs from CAN bus include

- PCM requests
- Engine output torque
- Brake switch
- ABS status signals
- Charging system voltage
- Engine RPM
- Engine coolant temperature
- Accelerator pedal position
- Vehicle speed
- A/C system requests

OUTPUTS The TCM controls the drive ratio to match vehicle needs. It can adjust the ratio during vehicle cruise to produce the maximum fuel economy, best emissions, or maximum pulling power. It continuously monitors ISS and OSS signals to ensure that the speeds match the desired ratio.

- The stepper motor, also called a **ratio control motor**, is a linear position motor that changes the position of the upper end of the pulley ratio link. The stepper motor controls the hydraulic ratio valve through the link, which in turn controls fluid flow to the piston. The lower end of this link moves with the floating side of the primary/drive pulley and the *ratio control valve* is connected to the center of this link. Movement of the stepper motor or the floating sheave will move the ratio control valve to produce a ratio change. ● **SEE FIGURE 129–8.**
  TCM outputs include
- Stepper motor that operates the ratio control valve, which controls the ratio changes commanded by the TCM.
- **Line pressure solenoid (LPS)**, which controls the line pressure to the transmission hydraulic system.

SECONDARY VALVE

FIGURE 129–9 Movement of either the stepper motor or primary floating sheave will move the ratio control valve to add or remove fluid from the primary pulley. The secondary valve maintains the necessary pulley pressure on the drive belt.

The TCM also controls fluid pressure to the secondary/driven pulley and torque converter as well as TCC lockup. Some vehicles use predetermined stepper motor position to mimic upshifts and downshifts.

CVT OPERATION

STARTING With no fluid pressure, the secondary pulley spring forces the floating side to a narrow, high-belt position, which in turn moves the primary pulley to a wide, low-belt position. This produces an underdrive that is always used as the vehicle starts moving. Continued fluid flow to the primary piston will change the ratio from an underdrive/reduction through 1:1 to an overdrive.

REVERSE A planetary gear set is needed for reverse-direction operation, and this is a simple planetary with a carrier that can be held by the reverse clutch. The input shaft drives the ring/internal gear, and the sun gear drives the shaft to the primary pulley.

FORWARD OPERATION A forward clutch is mounted on the input shaft from the torque converter; it is mounted inside a clutch drum that also contains the planetary ring gear. When it applies, the forward clutch drives the planetary sun gear so both the sun and ring gears are driven. This locks the gear set to produce a 1:1 ratio.

CVT TORQUE CONVERTER Most CVT transmissions use a low-profile elliptical torque converter with a lockup clutch. Since CVTs are infinitely variable, the torque converter is not needed once the vehicle is moving. Therefore, the converter is used to multiply the torque to get the vehicle moving from a stop, and then becomes a mechanical connection between the engine and the CVT. The torque converter clutch apply will occur at about 12 MPH (20 km/h) and stay locked until the vehicle comes to a stop. Some small vehicles with CVTs do not use a torque converter. The forward and reverse clutches are released for stops and one will be applied to start the vehicle moving.

PRESSURE TESTING A CVT

TYPICAL PRESSURES Measuring the CVT oil pressures is similar to performing pressure testing on conventional automatic transmissions/transaxles. Always check service information for the exact procedures to follow and the location of the pressure tap. ● **SEE FIGURE 129–10**.

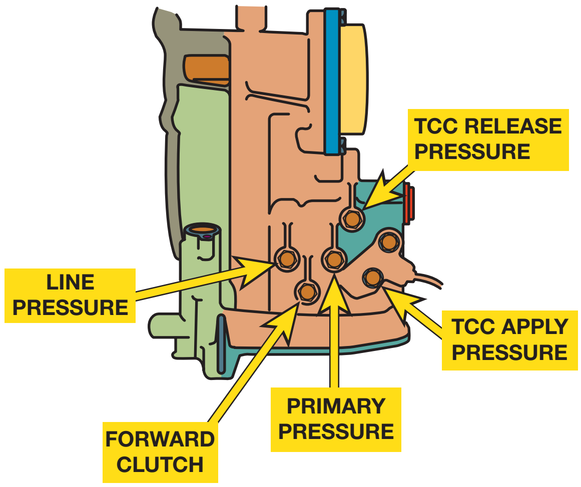

FIGURE 129–10 The pressure tap locations as found on a Dodge Caliber CVT transaxle.

WARNING

The pressure can exceed 1,000 PSI (6,900 kPa) and a leak from the tester could cause personal injury. Always uses a high-pressure gauge and follow the vehicle manufacturer's recommended procedures.

Typical pressures include

- Mainline pressure 70 to 900 PSI (485 to 6,200 kPa)
- Primary pressure 15 to 900 PSI (100 to 6,200 kPa)
- Secondary pressure 15 to 900 PSI (100 to 6,200 kPa)

CVT FLUID

CHECKING CVT FLUID LEVEL A dipstick is used to check the level in some units, and fluid may be poured into the dipstick pipe to bring the level up if it is low. CVT fluid is usually green to help distinguish it from conventional ATF.

CAUTION: Wipe off the dipstick before removing it to prevent any dirt from falling into the fill tube when checking the level of the fluid. Any dirt in the fluid can cause severe damage to the CVT transaxles.

REPLACING CVT FLUID When replacing the CVT fluid, make sure that the specified CVT fluid is used. There is often a drain plug on the transmission pan, and a filler hole located on the transmission case. When refilling the CVT, be sure to check the level regularly to make sure it is not being overfilled. Both the drain and filler plugs should have their gaskets replaced before installing them in their respective holes. Be certain to observe torque specifications when tightening these plugs to prevent damage to the threads in the transmission case and oil pan.

CVT FLUID OPTIONS The shop has two options when filling or replacing CVT automatic transmission fluid:

Option 1. The use of the exact specified fluid as recommended by the vehicle manufacturer is preferred in all cases. A minor disadvantage is that some fluids may be hard to find from local parts suppliers and may have to be purchased from a dealer. ● **SEE FIGURE 129–11**.

CASE STUDY

The Case of the Delayed Shift Subaru

The owner of a Subaru Legacy complained that the CVT (TR580) transmission was slow to engage from park to reverse and from drive to reverse. The technician assigned to the vehicle was able to verify that it required as long as four seconds to shift from drive to reverse or from neutral to reverse. After performing a through visual inspection, including a fluid level check, and not finding any issues, a scan tool was used to see if there were any transmission related diagnostic trouble codes. There were none so the technician checked for any technical service bulletins (TSBs) and found one (#16-97-15) that did address the customer complaint. In the TSB, there was a procedure to follow to relearn the TCM, which stated that this should be performed if there is a lag time greater than 1.5 seconds. The technician performed the relearn control procedure that included the following steps:

- Shift into "N" for 5 second, then shift into "R" for 3 seconds, and then shift back into "N". Repeat 10 times.
- Stay in "N" for 5 seconds, then shift into "D" for 3 seconds, and then shift back into "N". Repeat 10 times.

After 10 times, perform the "time lag test" again to confirm if this procedure corrected the customer complain.

The technician was pleased that the relearn procedure did result in a delay time of less than a second. The customer was very pleased too because it did not require an expensive repair.

Summary:

Complaint—Customer complained of excessive time into a drive gear.
Cause—The transmission needed to be relearned.
Correction—The relearn procedure as found in a TSB was used to relearn the shifting of the CVT. ● **SEE FIGURE 129–12**.

FIGURE 129–12 The "fix" to the customer concern was to perform a relearn procedure using the gear selector following the instructions found in a TSB.

Option 2. Use a multi-vehicle fluid, also called *universal CVT fluid,* that is designed to meet the specifications of several different makes and both belts and chains used in CVTs. This is commonly used by many shops and can be successfully used if the fluid is within the specified viscosity and the fluid manufacturer states that it meets the O.E. requirement for friction coefficient.

CVT-RELATED DIAGNOSTIC TROUBLE CODES

For some of the diagnostic trouble codes (DTCs) associated with a CVT transmission and the description, ● **SEE CHART 129–2**.

DUAL-CLUTCH AUTOMATIC TRANSMISSIONS

PURPOSE AND FUNCTION A dual-clutch automatic transmission or transaxle uses a manual-type transmission and two clutches that engage either the inner or outer transmission shaft. This type of transmission is designed to achieve the following goals, compared to a conventional automatic transmission or transaxle equipped with a torque converter and planetary gear sets.

1. Improve fuel economy.
2. Reduce the cost of assembly by using manual transmission components.
3. Improve the speed of gear changes.
4. Provide smoother operation.

TERMINOLOGY A dual-clutch automatic transmission/transaxle can also be referred to as

CHART 129–2

Typical continuously variable transmission (CVT) diagnostic trouble codes (DTCs) and code description. Transmission-related DTCs are usually P07XX or P08XX, where XX represents the specific fault code.

- **Direct shift gearbox (DSG)**. Most commonly used by the VW/Audi Group (VAG) of vehicles.
- **Porsche Doppelkupplung (PDK)**. The Porsche term used to describe their dual-clutch automatic.
- **Automated manual transmission (AMT)**. Original term no longer commonly used.
- **Twin clutch transmission**. Another variation of the term used for a dual-clutch automatic transmission.

PARTS AND OPERATION A dual-clutch automatic transmission/transaxle uses two clutches that are mounted together. One clutch drives the odd number gears (first, third, fifth, and seventh). The other clutch drives the even number gears (second, fourth, and sixth). ● **SEE FIGURE 129–13**.

The shifts occur without interrupting the torque from the engine by applying torque to the clutch while at the same time disconnecting the other clutch. These actions result in a rapid shift without the slight delay usually associated with an automatic transmission.

There are two types of clutches used depending on application:

1. Dual dry clutches are used in low powered vehicles, such as small front-wheel-drive vehicles. ● **SEE FIGURE 129–14**.
2. Dual wet clutches are often used in higher powered vehicles.

Vehicles that use a dual-clutch automatic-type transmission /transaxle include certain models of Audi, Nissan, Mercedes, BMW, Porsche, Ford, Ferrari, VW, and Mitsubishi.

ADVANTAGES The advantages of a dual-clutch automatic transmission/transaxle compared to a conventional automatic transmission include

1. Quicker throttle response
2. No drop in engine speed when the driver releases the throttle
3. Instant gear changes
4. Improved fuel economy

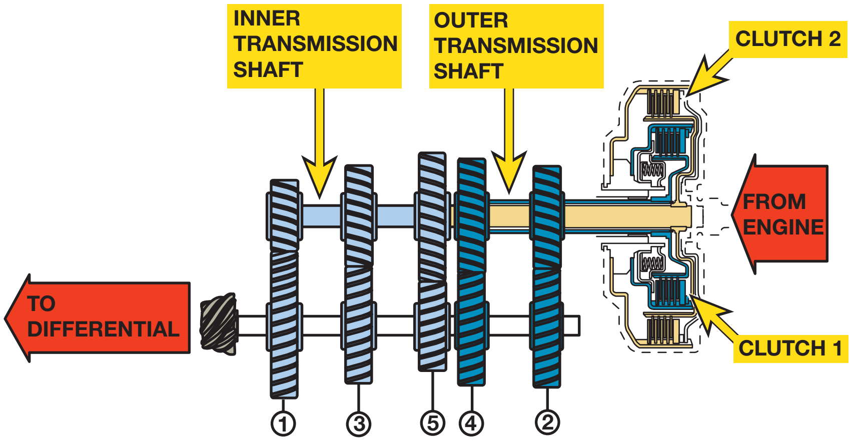

FIGURE 129–13 A dual clutch automatic uses the best features of an automatic transmission without the power loss of a torque converter.

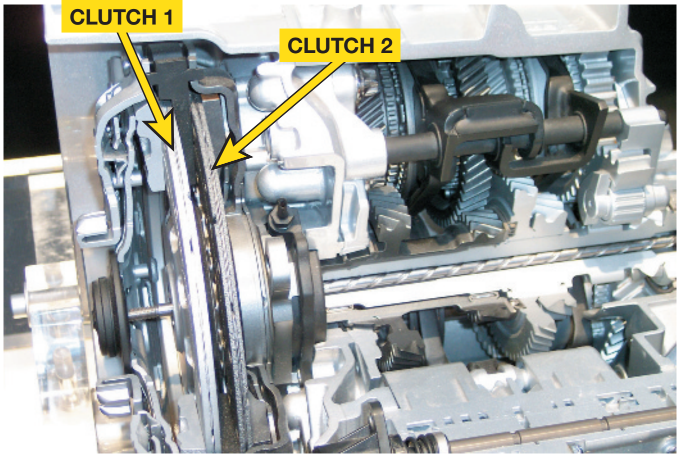

FIGURE 129–14 Dual-clutch automatic transaxles that use two dry clutches. The larger clutch drives the odd number gear ratios (first, third, and fifth) and the smaller clutch drives the even numbered gear ratios (second, fourth, and sixth).

DISADVANTAGES The disadvantages of a dual-clutch automatic transmission/transaxle compared to conventional or continuously variable automatic transmissions include

1. No torque multiplication advantage of a torque converter
2. Not as fuel efficient as a continuously variable transmission (CVT) or transaxle

DUAL-CLUTCH TRANSAXLE

TERMINOLOGY A dual-clutch transaxle is essentially two transmissions built into one case. Each portion is driven by one of the clutches, and these clutches are applied, one at a time, to transfer power. A dual-clutch transmission is essentially an automatic transmission that uses manual transmission-style gear layout and synchronizers with two countershafts. The shifts can occur vary rapidly, being controlled by how fast each clutch can be applied and with partially engaging one clutch while slipping the other during shifts.

CONCENTRIC AND PARALLEL CLUTCH DESIGNS There are two basic wet clutch designs used in dual-clutch automatic transmissions:

1. A **concentric clutch** (also called a *nested-type clutch*) is a design where both plates share the same vertical plane and provide a shorter assembly.
2. A **parallel clutch** design is used in a side-by-side arrangement. ● **SEE FIGURE 129–15**.

GEAR ARRANGEMENTS The 1–3 and 5 synchronizer assemblies are driven by clutch 1 and the 2–4 and 6-reverse synchronizers are driven by clutch 2. Vehicle movement begins with the 1–3 synchronizer shifted to first gear and clutch 1 applied. The 2–4 synchronizer is then shifted into second gear by a hydraulic servo, and the 1–2 upshift will occur when clutch 1 is released and clutch 2 is applied. The remaining upshifts occur in the same manner, with the synchronizer preshifted or shifted early, and the actual shift occurring when the clutches are cycled. ● **SEE FIGURE 129–16**.

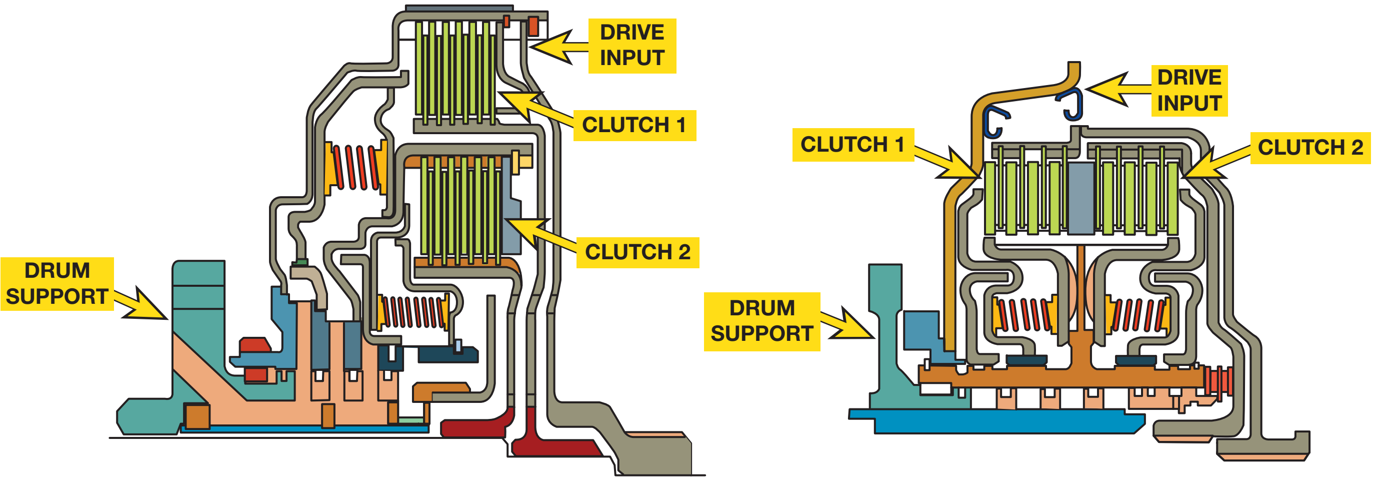
The driver can control the transmission/transaxle using a floor-mounted shift lever or one of a pair of paddles mounted on the steering wheel.

- Clutches 1 and 2 are applied by hydraulic pressure, similar to automatic transmission clutches.

FREQUENTLY ASKED QUESTION

How Does a Dual-Clutch-Type Transmission Achieve Better Fuel Economy?

One of the advantages of a dual-clutch automatic is that it is able to provide improved fuel economy over a conventional torque converter-type automatic. One strategy is to have the unit go into neutral when the vehicle is stopped by disengaging the clutches. This allows the engine to remain running but reduces the load on the engine, which improves fuel economy and reduces vibrations. The clutch is engaged when the driver releases the brake.



(a) (b)

FIGURE 129–15 (a) A concentric (nested) clutch design, the assembly is shorter in length but taller in height. (b) A parallel clutch design is longer but has a smaller diameter drum assembly.

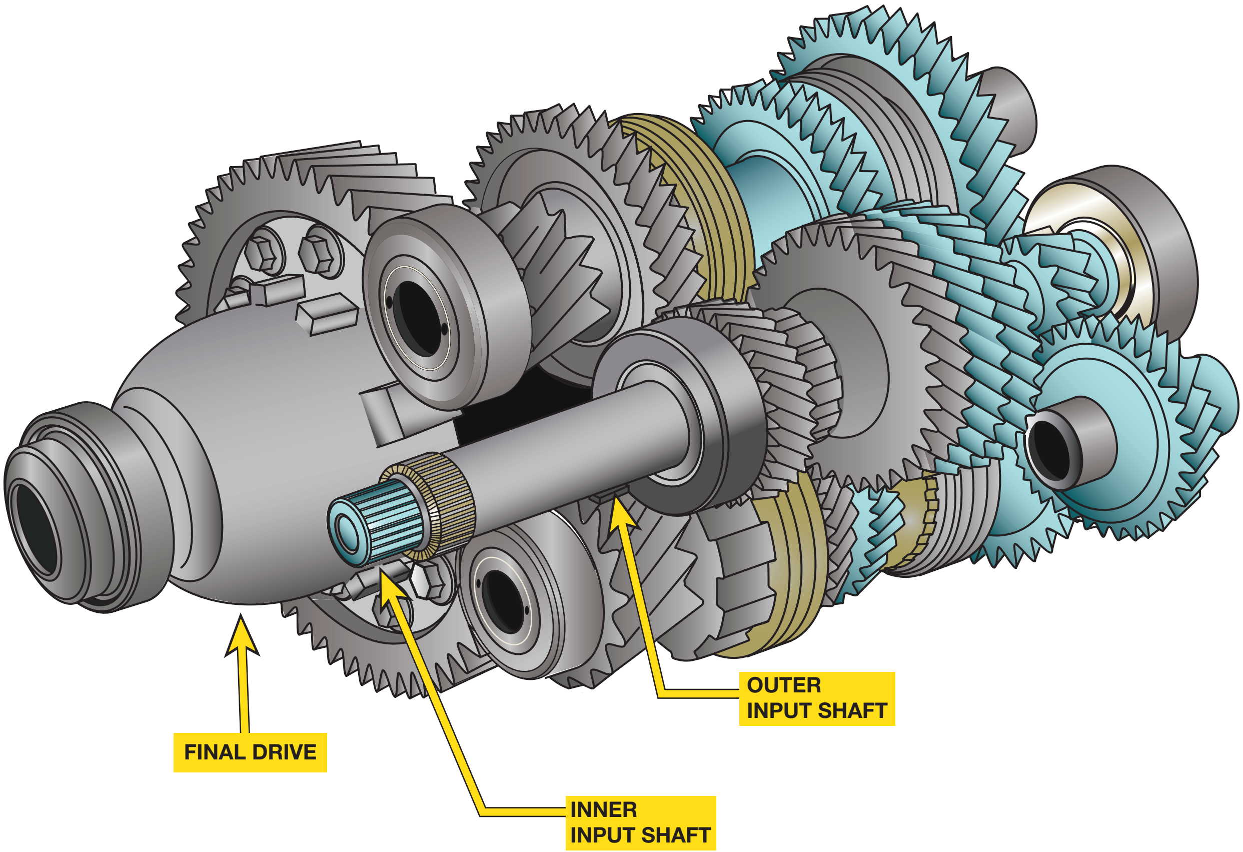


FIGURE 129–16 Notice the two concentric input shafts. Each shaft is splined to a clutch.

- The hydraulic flow to the clutches and servos is controlled electronically by a control module.

SPEED SENSORS Speed sensors include

- **Engine RPM sensor.** Inputs the engine RPM to the TCM from the sensor located on the clutch drum housing.
- **Speed sensor input shaft odd gears.** Gives the TCM information on input shaft RPM (after the C1 clutch) for odd gears, 1, 3, 5, and R.
- **Speed sensor input shaft even gears.** Gives the TCM information on input shaft RPM (after the C2 clutch) for even gears, 2, 4, and 6.

TEMPERATURE SENSORS Temperature sensors include

- **Clutch fluid temperature.** Used to measure the temperature of the fluid leaving the clutches.
- **Transmission fluid temperature.** Used to measure the temperature of the fluid in the transmission.
- **Oil temperature sensor.** Located on the TCM, which provides information on transmission oil temperature.

The TCM uses temperature information to determine correct system pressure, for controlling the clutch, for cold starts, and for overheating protection.

PRESSURE SENSORS Pressure sensors give the TCM information on hydraulic pressure of the clutches. The TCM supplies the sensors with 5 volts. The sensors register the oil pressure to control the clutch pressure so that the TCM can control the solenoids to provide correct clutch pressure for each clutch.

POSITION SENSORS Position sensors include

- *Fork position sensors*—These sensors give the TCM information on the position of the four gear shift forks that handle shifting in the transmission. Includes 1-R; 3-5; 2-4; and 6-N.
- *Transmissions Range Sensor (TRS)*—This sensor provides the actual P R N D gear selection.

The transmission electronic control module uses information from the sensors to determine the proper clutch and shift servo operation. Once the TCM determines the required gear range and driving conditions, actuators are turned on or off to control hydraulic pressure, gear selection, clutch control, and shift lock.

FREQUENTLY ASKED QUESTION

Why Is the TCM Using the Position of the Steering Wheel?

The steering wheel position (SWP) sensor information is sent to the transmission control module (TCM) over the network to prevent the transmission from upshifting when cornering. This helps the driver by allowing the vehicle to be accelerated when exiting a corner. If the steering wheel position was not part of the shift program, the transmission might likely upshift to a higher gear as the vehicle slows, then the transmission may have to downshift again when the vehicle exits the corner.

SOLENOIDS A typical dual-clutch automatic transmission/transaxle includes the following solenoids:

- **Line pressure solenoid (LPS)**—Controls system pressure in the transmission by directing the hydraulic oil to clutch, shifting, cooling flow, and then returning the oil to the oil sump.
- **Clutch cooling flow solenoid (CCFS)**—Controls hydraulic oil for cooling of clutches.
- **Shift cooling multiplex solenoid (SHCMS)**—Controls position of gearshift forks as well as cooling of clutch.
- **Clutch shift multiplex solenoid (CSMS1)**—Leads the pressure between odd clutch and shifting, activates odd gears, as well as controls cooling flow for clutches.
- **Clutch shift multiplex solenoid (CSMS2)**—Leads the pressure between even clutch and shifting, controls cooling flow for clutches, and can turn off the valve for dumping clutch pressure.
- **Clutch shift pressure solenoid (CSPS1)**—Controls hydraulic pressure for odd clutch or shifting.
- **Clutch shift pressure solenoid (CSPS2)**—Controls hydraulic pressure for even clutch or shifting.
- **Clutch pressure cut (CPCUT)**—Safety valve that controls pressure dumping in the hydraulic system.
- **Shift select solenoid (SHSS1)**—Controls shifting for gearshift fork 1 and 3.
- **Shift select solenoid (SHSS2)**—Controls shifting for gearshift fork 2 and 4.

SHIFT FORK POSITION The transmission control module (TCM) operates shift solenoids. These pistons apply force to the shift forks through lever points to help increase the force applied. Both an even and an odd gear can be commanded at the same time in parallel. Position sensors are located inside the case, and this information is used by the TCM to determine the actual position of each shift fork. ● **SEE FIGURE 129–17**.

DIAGNOSIS AND SERVICE

DIAGNOSTIC PROCEDURES To diagnose faults with dual clutch automatic transmission/transaxle systems, follow the recommended procedures found in service information. The usual procedure involves the following steps:

STEP 1 Verify the customer concern (complaint). This step includes trying to duplicate what the customer or driver is concerned about.

STEP 2 Perform a thorough visual inspection, including

- Checking the level and condition of the fluid
- Checking the drivetrain mounts for damage or faults

STEP 3 Check service information for the specified procedure to follow. Most vehicles require the use of a factory-brand scan tool. ● **SEE FIGURE 129–18**.

FIGURE 129–18 The use of a factory or a factory-level aftermarket scan tool is often needed to diagnose the dual clutch transmission system.

STEP 4 Follow the troubleshooting procedure as specified to fix the root cause of the problem. This means following the instructions displayed on the scan tool or service information.

STEP 5 Repair the fault.

STEP 6 Road test the vehicle under the same conditions that were performed to verify the fault to ensure that the repair is completed.

TYPICAL DIAGNOSTIC TROUBLE CODES As part of any diagnostics, checking for diagnostic trouble codes is one of the first steps. ● **SEE CHART 129–3** for some examples of dual-clutch automatic transmission-related DTCs.

FLUID AND FILTER SERVICE The transmission fluid is usually high-quality synthetic oil, which is unique for this type of transmission. Dual-clutch transmission fluid is usually green to help identify it as a unique fluid and prevent someone from using conventional automatic transmission fluid. Always use the specified fluid.

For example, the Ford Dry Dual Clutch Fluid is specifically formulated for use in the DPS6 power shift twin dry clutch transmission. This fluid is used only in transmissions requiring a fluid meeting WSS-M2C200-D2.

Most dual-clutch automatic transmissions/transaxles use an external filter that is serviceable and an internal filter that is a nonserviceable part unless the unit is totally disassembled. Always follow the vehicle manufacturer's recommended fluid and filter service intervals.

AUTOMATIC TRANSMISSION FLUID

PURPOSE AND FUNCTION **Automatic transmission fluid (ATF)** is a highly refined oil with a viscosity similar to SAE 20W-20 oil and is specially designed for use in an automatic transmission. Newer ATFs are lower in viscosity and are similar to SAE 0W-10 oil. The purposes and functions of ATF are as follows:

- Transfers power in torque converter
- Provides hydraulic pressure in clutches and servos
- Lubricates bearings, bushings, and gears
- Transfers heat to cool transmission parts
- Provides the correct friction for clutch and band application
- Acts as the medium to control transmission shifting by traveling through passageways, acting on valves, and being directed by solenoids

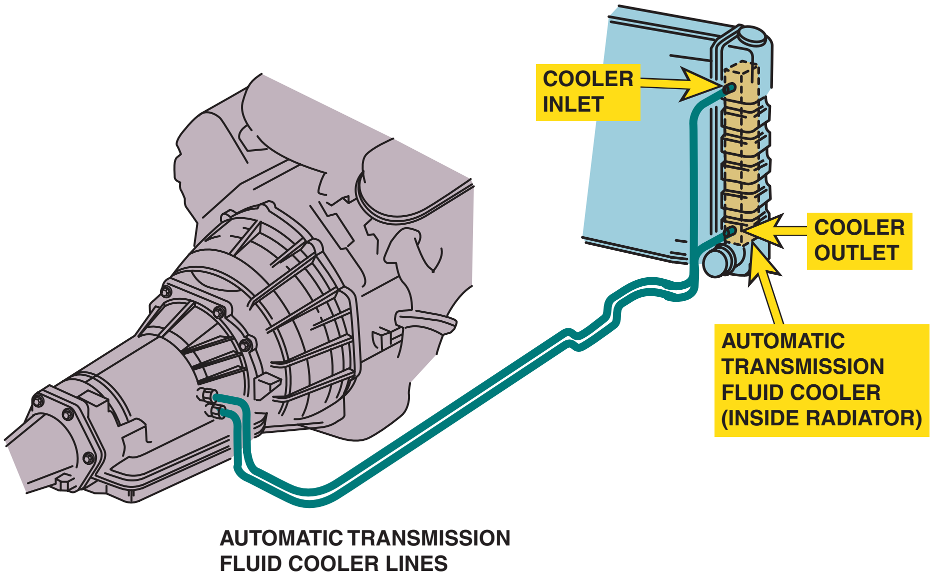
TYPES The three basic types of ATF include

1. **Non-friction modified.** The first ATF did not have friction reducing additives. This type of fluid was used in early band-type automatics (all first generation). Type F ATF is an example of a non-friction-modified ATF.
2. **Friction modified.** Friction-modified ATF types include Dexron.
3. **Highly friction modified.** All current original equipment manufacturers use automatic transmission fluids that are highly friction modified. These include Dexron VI, Mercon V, ATF + 4, and ATF WS. Friction modifiers added to the ATF, along with hydraulic devices (orifices and accumulators) and electronic controls, help produce "proper shift quality."

TYPICAL ATF APPLICATIONS Automatic transmission fluid is formulated to work in specific transmissions. Using the specified fluid is the key to proper operation. Check service information for the exact automatic transmission fluid to use.

AUTOMATIC TRANSMISSION FLUID COOLER

PURPOSE AND FUNCTION The torque converter generates a great amount of heat because of fluid shear as its internal elements spin at different speeds in relation to each other. The greatest amount of heat is generated when the vehicle is operating under a heavy load and the torque converter clutch is disengaged. The ATF can reach high temperatures (over 250°F [120°C])



COOLER INLET
COOLER OUTLET
AUTOMATIC TRANSMISSION FLUID COOLER (INSIDE RADIATOR)
AUTOMATIC TRANSMISSION FLUID COOLER LINES

FIGURE 130–1 Automatic transmission fluid is routed from the torque converter, where most of the heat is generated, to the radiator where it is cooled. The fluid then returns to the transmission/transaxle to lubricate the bearings and bushings.

very quickly, which is why an automatic transmission fluid cooler is used. Most vehicles use a small section of the engine cooling system radiator to transfer heat from the ATF to the coolant, which cools the ATF.

PARTS AND OPERATION Automatic transmissions/transaxles use a pump to circulate ATF and provide the necessary hydraulic flow to operate the hydraulic components of the unit. The ATF is pumped (directed) from the torque converter (greatest source of heat) to the cooler when the torque converter clutch is not applied. The ATF flows through the cooler, which has the following characteristics:

- It is a separate section of the radiator tank.
- The hotter transmission fluid gives up heat to the cooler engine coolant.
- Some manufacturers use a *cooler bypass valve* that will allow fluid to bypass the cooler if restricted. Some vehicles also use a temperature controlled valve to block the flow of fluid during low-temperature operation such as is used in Dodge (Ram) trucks.
- Many vehicles with towing packages use a larger cooler or a combination of a liquid-to-liquid and a liquid-to-air cooler in series with each other to handle the extra heat load of towing.

The ATF returns to the transmission/transaxle to passages that lubricate the internal moving parts. This returned fluid is called **lube oil**. ● **SEE FIGURES 130–1 AND 130–2**.

CAUTION: Because the lube oil uses the ATF flowing from the cooler, if there is a blockage in the cooler, the transmission/transaxle may not have enough fluid flow to properly cool or lubricate the bearings and bushings inside the unit, leading to wear and eventually premature failure.

TRANSMISSION FLUID HEATER The cooler is located in the radiator in most vehicles and, as a result, the coolant will also warm the ATF when the temperatures are cold. Some vehicles are equipped with a transmission fluid heater that uses the coolant to warm the fluid when it is cold. Warm fluid works better than cold fluid to lubricate moving parts inside the unit. ● **SEE FIGURE 130–3**.

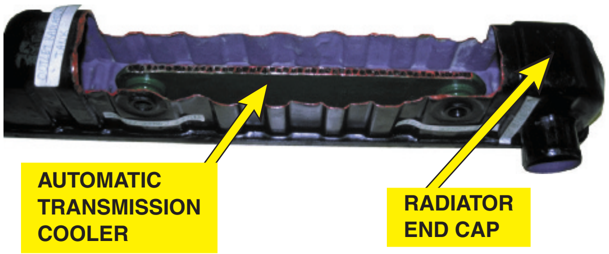


FIGURE 130–2 A cutaway of a typical radiator showing the automatic transmission cooler. The heat from the automatic transmission fluid is released to the engine coolant. The engine coolant also warms the fluid as soon as the coolant flows through the radiator.

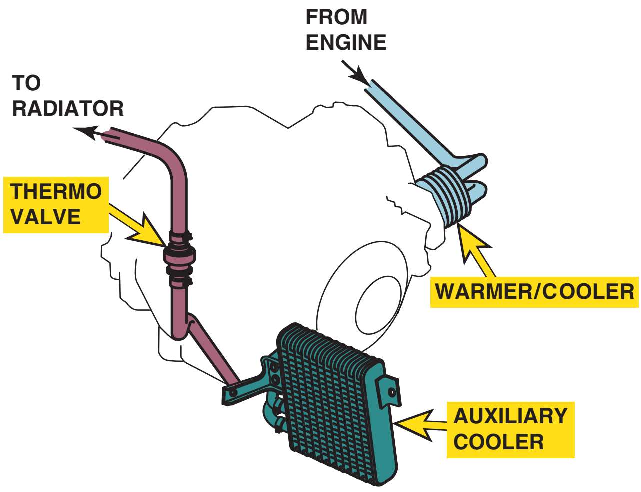

FIGURE 130–3 Engine coolant from the engine block flows through the passages in the cooler/warmer, and then out through the thermo valve to the upper radiator tank. The thermo valve uses a wax element–type valve to control the flow of engine coolant through the case-mounted cooler/warmer. The thermo valve improves the ATF warm-up times and maintains ATF temperature within the optimum operating range between 170° and 190°F (77°and 88°C)

TRANSMISSION OIL PUMP

PURPOSE AND FUNCTION Every hydraulic system requires a *pump* to supply fluid flow and pressurize the system. However, the pump itself does not develop pressure but instead pressure occurs when there is a resistance to flow. Initially, fluid flows freely when a hydraulic circuit is empty or partially filled. Once the circuit is completely full, there is a resistance to further flow. At this point, pressure begins to build up in the circuit as the pump continues to create flow.

PARTS AND OPERATION Most oil pumps mount directly behind the torque converter and are usually driven by the converter drive hub. This connects the pump to the engine and allows it to respond quickly to engine demand. This type of oil pump operates whenever the engine is running. ● **SEE FIGURE 130–4**.

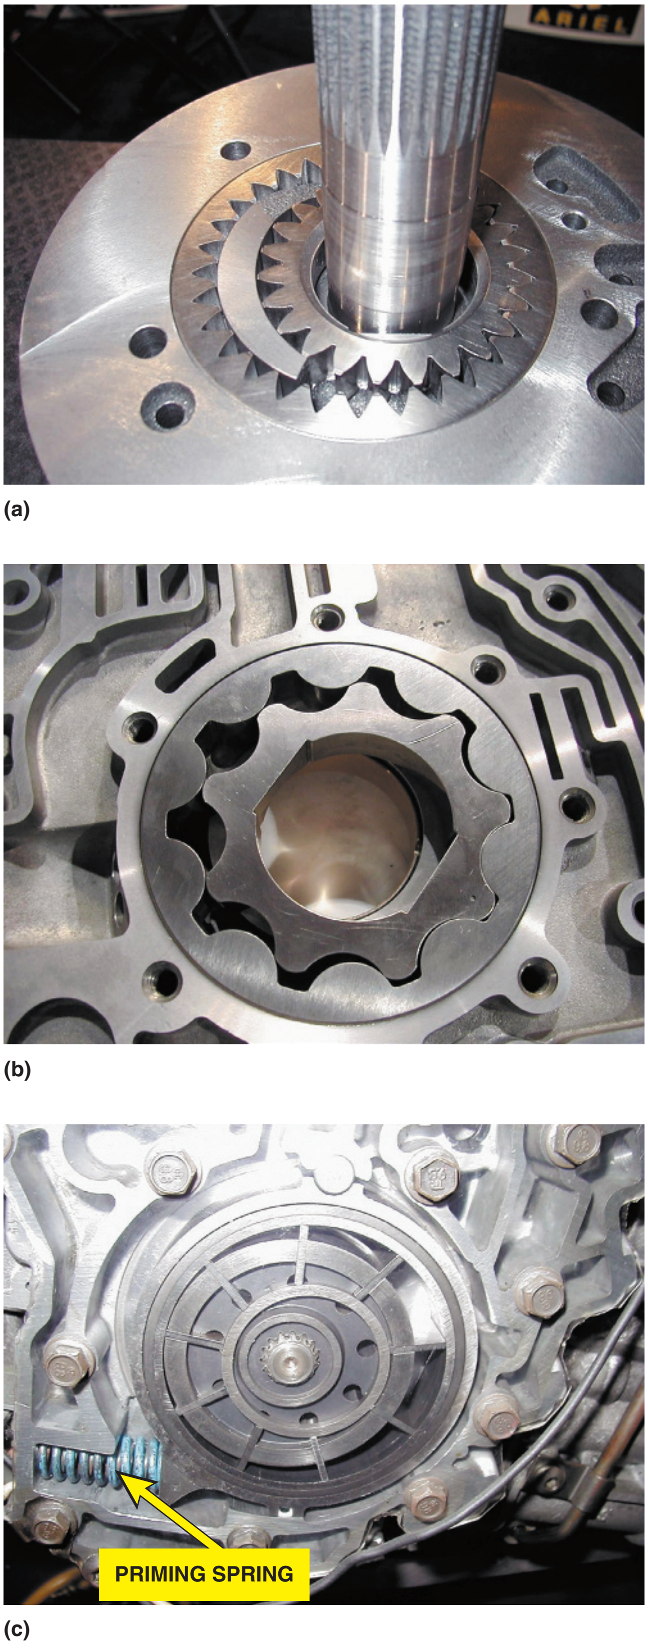

FIGURE 130–4 (a) Gear-type pump. (b) Gerotor-type pump. (c) Vane-type pump.

PRESSURE REGULATION Transmission oil pumps are capable of creating an excessive amount of pressure quickly; therefore, every transmission uses a **pressure regulator valve**, or *pressure control valve,* to control hydraulic pressure. This is usually a spool valve and spring combination. This regulated pressure, commonly known as *mainline pressure,* is the working pressure for the entire hydraulic system. Most pressure regulator valves balance pump pressure on one side of the valve against a preset spring force acting on the other side of the valve.

When hydraulic pressure is greater than the spring force, the valve moves in its bore far enough to uncover an exhaust port. ● **SEE FIGURE 130–5**.

The exhaust port provides a low-pressure path to the transmission oil pan (sump) where excess ATF is stored. Excess pressurized fluid flowing through this port reduces system pressure. When hydraulic pressure drops below spring pressure, the regulator valve closes the port and pressure begins to build up again.

In operation, the opening and closing of the exhaust port occurs many times per second. This sequence of events achieves a steady pressure as the valve balances both the spring pressure and the hydraulic pressure. Because of this action, this type of valve is sometimes called a **balance valve**.

VARIABLE DISPLACEMENT PUMP Many newer automatic transmissions and transaxles use a variable displacement pump to reduce the power needed to achieve fluid pressure to the amount required instead of being based on pressure alone. The use of a variable displacement pump helps improve fuel economy and reduce exhaust emissions. ● **SEE FIGURE 130–6**.

ELECTRONIC PRESSURE REGULATION Electronic automatic transmissions/transaxles often regulate hydraulic system pressure using computer-controlled solenoids called any of the following:

- **Pressure control solenoids (PCS)**
- **Electronic pressure control (EPC)**
- **Pressure control (PC)**
- **Variable force solenoids (VFS)**
- **Force motors**

An onboard computer switches the solenoids on and off very quickly using pulse-width modulation (PWM). The solenoid pushes against an internal valve, which opens and closes the hydraulic circuit it regulates. **Electronic pressure control** allows precise hydraulic system pressure regulation and can also be used to modify the timing and feel of transmission shifting. ● **SEE FIGURE 130–7**.

(TCM) to provide the specific pressure needed by the system based on input from the sensors such as vehicle speed and engine load. Line pressure is reduced to improve fuel economy because lowering pressure reduces draw on the engine, which is driving the pump.

Typical line pressures include

- Normal line pressure = 60 to 120 PSI (414 to 830 kPa)
- The accelerator pedal pressed to wide open throttle (WOT) = 90 to 150 PSI (620 to 1,304 kPa)
- The gear selector in reverse or manual low (1) = 150 to 300 PSI (1,034 to 2,068 kPa)

Higher pressures are necessary in reverse because these apply devices are usually smaller and or have fewer clutch plates to ensure that the clutches are firmly applied, in order to avoid slippage when the engine is producing maximum torque.

APPLY OR HOLDING DEVICES

PURPOSE AND FUNCTION **Apply devices** or **holding devices** are the mechanical or hydraulic assemblies that provide the force to hold or drive members of a planetary gear set.

Automatic transmissions typically use the following as apply devices:

- Transmission bands
- Multiple-plate clutches
- One-way clutches

BANDS

TERMINOLOGY Transmission bands are holding (braking) devices. The planetary gear set member held is known as a **reaction member**. A **transmission band** stops and holds one planetary gear set member so that another member can react against the held member and develop output motion. The reaction member has a control surface for the band to ride on, known as a drum. The band directly affects the drum, and the drum directly affects the planetary gear set member. ● **SEE FIGURE 130–8**.

The band provides a holding force around the outside of the drum, closing tightly to keep it from turning. To repeat, a transmission band is a holding device and is not capable of driving any member of the planetary gear set.

Transmission bands are made of cast iron or steel with friction material lining on the inside surface. Transmission design and component size dictate the type and size of band used. Bands fall into one of two categories:

- Single wrap
- Double wrap

The single-wrap band is a simple one-piece design, while the double-wrap band is a split band with overlapping ends. Bands may also be classified as either flexible or fixed, depending on how well they hold their shape when they are off the drum. ● **SEE FIGURE 130–9**.

HYDRAULIC SERVOS A band is applied by using a hydraulically operated piston that travels inside a machined cylinder bore.

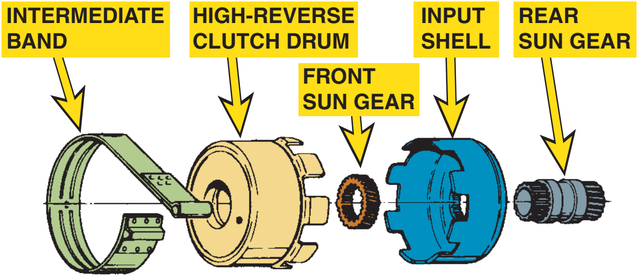

FIGURE 130–8 Gear set members are attached to a drum and are held stationary when the band applies.

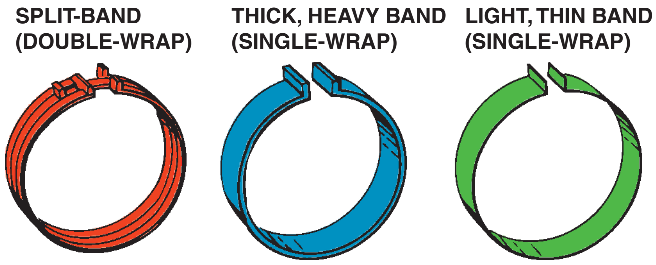

SPLIT-BAND (DOUBLE-WRAP)
THICK, HEAVY BAND (SINGLE-WRAP)
LIGHT, THIN BAND (SINGLE-WRAP)

FIGURE 130–9 Transmission bands come in several designs and thicknesses.

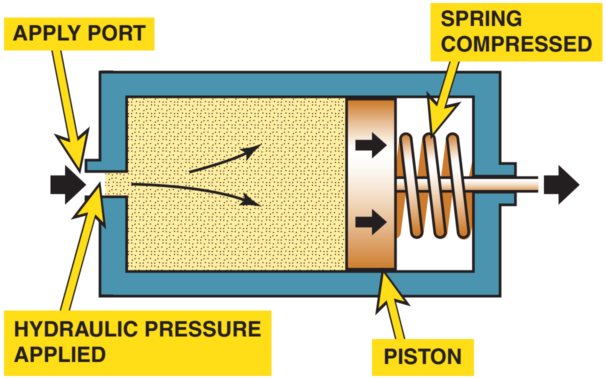

FIGURE 130–10 A servo uses hydraulic pressure to move a piston, which applies a band.

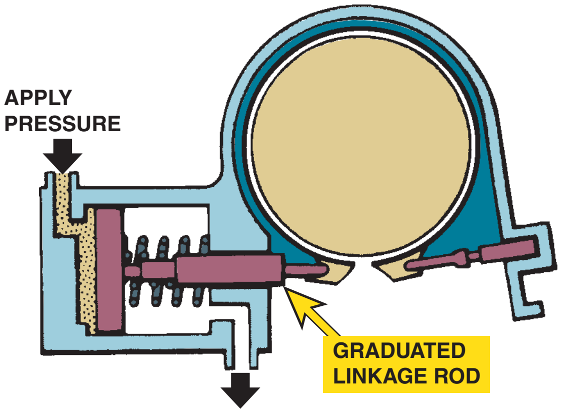

FIGURE 130–11 One end of a band is held stationary and the other end is attached to the servo.

This piston and cylinder assembly is known as a **servo**. ● **SEE FIGURE 130–10**.

A piston return spring normally holds the servo piston in its unapplied position. To apply the band, hydraulic fluid, under pressure, enters the servo cylinder and acts on the piston. The piston begins moving once hydraulic pressure overcomes spring force.

SERVO LINKAGES A mechanical rod, called a *strut,* and linkage attaches to the piston and connects it to the band. As the piston moves, the linkage applies the band by tightening it around the drum. Servo *rods* and *struts* transfer the servo apply force to the transmission band. Rods are round metal bars and struts are flat metal plates. These may be used at either or both ends of the band. Linkages connect the band to the servo or an anchor. One end of a band is often anchored to the transmission case and whenever the band is applied, the drum that the band wraps around is held from rotating. ● **SEE FIGURE 130–11**.

NOTE: Some bands have a provision for adjustment and may be adjusted in vehicle while others are adjusted or set during transmission assembly.

MULTIPLE-PLATE CLUTCHES

TERMINOLOGY Like a transmission band, a multiple-plate hydraulic clutch is a type of apply device. Clutches have more friction area so they can develop more force and handle more torque than a band, and they are self-adjusting.

PARTS The **multiple-plate clutch** consists of plates, a piston, drum (retainer), and snap ring. Hydraulic pressure acts upon the clutch piston, which moves in the drum. The piston movement compresses the plates together to provide either a holding or driving function. When the pressure is released, the piston returns to an unapplied position via a return spring assembly. The entire assembly is commonly known as a **clutch pack**. ● **SEE FIGURE 130–12**.

The plates of a multiple-plate clutch assembly consist of a friction plate alternated with steel plates.

- A friction plate, also called simply a *friction,* has a rough surface friction material applied to both faces. The friction (clutch lining) material is made from a mixture of natural and synthetic fiber. Natural fibers include cotton or wood (paper), and synthetic fibers are aramid (Kevlar®) or carbon. The exact mixture is determined by the transmission engineer to provide the desired heat resistance and durability standards.
- A steel plate, also called simply a *separator plate* or *steel,* has a smooth, flat surface finish with no friction material.
- Some transmissions may not have separate frictions and steels but rather combine them. One side of the plate will be coated with the frictional surface while the other side is flat metal like the steels.
- Collectively, the friction and steel plates are called clutch plates.

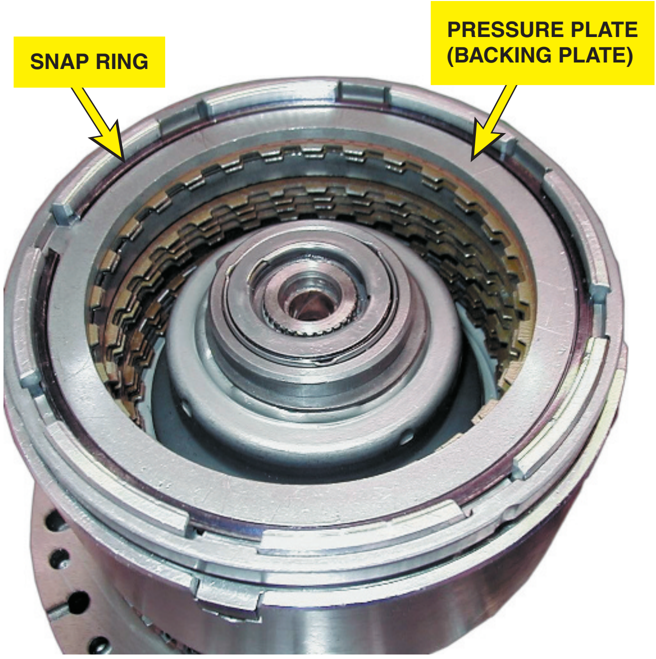

FIGURE 130–13 A typical clutch pack assembly.

Generally, the steel plates have splines on their outer edge, while the friction plates have splines on their inner edge. Each set of splines engages matching splines on a

- Shaft
- Drum
- Planetary gear set member or
- Transmission case

The piston compresses the clutch plates against a thicker reaction plate known as the **pressure plate**. Pressure plates may be used at one or both ends of the clutch pack and are available in selective (specific) sizes for adjusting clutch pack clearance. The pressure plate and clutch assembly components fit into either a **clutch drum** (retainer) or a machined bore in the transmission case. Snap rings retain all the clutch assembly components and are available in selective (specific) sizes for adjusting clearance. ● **SEE FIGURE 130–13**.

Some transmissions use a special wave-type spring to return the piston and cushion clutch applications. The piston returns to an unapplied position via a return spring assembly. These springs are designed to return the piston to the released position when apply fluid pressure is removed from the clutch pack. The two types of springs commonly used are the coil spring and the Belleville spring.

CLUTCH OPERATION To apply the clutch, pressurized fluid enters the drum through an internal passage in the input shaft. When the clutch applies, hydraulic pressure acting on the piston squeezes the two sets of plates together to mechanically connect the two components that engage the splines of the plates.

The fluid acts on the piston and moves it against return spring force to clamp the clutch plates together and hold them against the pressure plate. ● **SEE FIGURE 130–14**.

The friction between the plates then locks the clutch drum to the hub, causing them to turn as one unit.

To release the clutch, hydraulic fluid to the apply side of the piston is cut off and exhausted through an exhaust port. The piston return springs, which were compressed when the clutch was applied, are now free to expand and move the piston back, allowing the clutch plates to disengage.

TWO TYPES OF CLUTCHES Although a multiple-plate clutch is an apply device similar to a transmission band, it differs from a band because it can also be used to drive members of planetary gear sets as well as hold them. There are two types of multiple-plate clutches.

1. **Holding (braking) clutches.** A clutch contains frictions discs which are splined to one member and the steel disc are splined to another member of a planetary gearset. When the clutch is applied, the friction surfaces are clamped or held together keeping whatever the clutch plates are splined to from rotating. ● **SEE FIGURE 130–15**.
2. **Driving clutches.** There are two types of multiple-plate driving clutches, and both types are commonly used in automatic transmissions. In one configuration, splines connect a set of friction plates to the transmission input shaft so that these plates function as the driving member. The alternating set of steel plates is splined to the inside of the clutch drum and serves as the driven member. When the clutch is released, the drive plate rotates with the input shaft, but they do not drive the driven plate that splines to the drum.

   When the clutch applies, the piston takes up clearance and forces both sets of plates firmly together. Now, the input shaft and drum rotate together at the same speed and torque transfers from one gear set member to another. A passageway carries fluid to the clutch apply piston.

   With the second driving clutch configuration, the drum connects directly to the input shaft so the drum always rotates with the shaft. Splines connect the steel plate to the

inside of the drum and the friction plate to the outside of a clutch hub. When the clutch applies, hydraulic pressure compresses the clutch pack to lock the drum and clutch hub together. The input shaft then drives the output shaft and both turn at the same speed.

ACCUMULATORS

PURPOSE AND FUNCTION An accumulator cushions or dampens the apply force during a shift. An accumulator reduces hydraulic pressure surges by temporarily diverting part of the fluid flow in a hydraulic circuit into a parallel circuit or chamber. Accumulators can be described as "hydraulic shock absorbers" because they absorb or reduce the shock of engagement of the clutch or band. The diversion allows pressure in the main apply circuit to increase gradually and provides a smooth engagement of the band or clutch.

Piston-type accumulators look and function much like servo pistons. In fact, some piston-type accumulators share a bore with one of the transmission servos. This common bore design is known as an **integral accumulator**. ● **SEE FIGURE 130–16**.

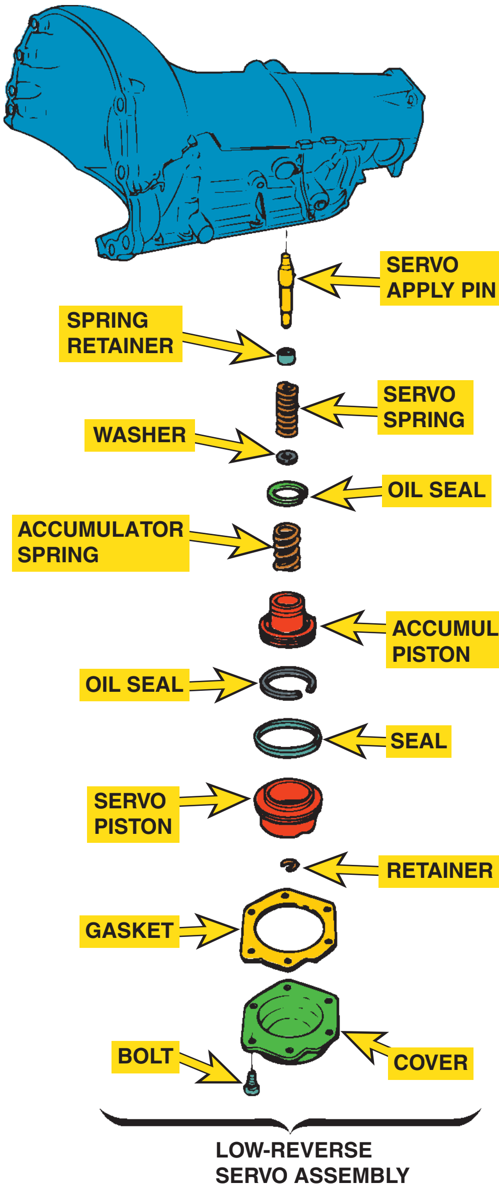

FIGURE 130–16 An integral accumulator is combined with a servo in a single bore in the transmission housing.

OPERATION As hydraulic pressure enters both circuits, the clutch piston or band servo piston starts to move first. Once the clearance is taken up and resistance increases, the circuit pressure increases. This is when the accumulator piston starts to dampen the clamping force and time of the apply device. The accumulator piston area and spring are designed to absorb fluid during the clutch circuit pressure rise when the clutch piston stops moving. The result of this dampening action results in a slight increase in the clutch application. When the time is increased between the initial clutch application and complete application of the clutch, the result is a smoother shift.

NOTE: Accumulators are disappearing in modern, electronic transmissions due to adaptive learning. The PCM or TCM measures the shift time, and if it is too long or too short, it will raise or lower line pressure so shift time matches the programming.

ONE-WAY CLUTCHES

TERMINOLOGY Another common type of automatic transmission device is the **one-way clutch (OWC)**, or overrunning clutch. Like a transmission band, a one-way clutch is always a holding device. One-way clutches are either roller or sprag clutches, although the roller clutch is more common.

ONE-WAY ROLLER CLUTCH A one-way roller clutch consists of a hub, rollers, and springs that fit inside a drum. The inner circumference of the drum has a series of machined ramps, or cam cuts, to accommodate the rollers and springs. Each ramp is narrower at one end than at the other.

If the drum is held while rotating the hub clockwise, the rollers will compress their springs and move toward the larger end of the ramps. This unlocks the clutch because there is enough clearance between the rollers and the drum for the hub to freewheel.

Rotate the hub counterclockwise while holding the drum. The rollers move toward the narrow end of the ramp, wedging themselves between the hub and drum to lock the clutch. With the rollers at the narrow end of the ramp there is no roller-to-drum clearance. Therefore, the hub cannot turn counterclockwise because the drum is being held. ● **SEE FIGURE 130–17**.

ONE-WAY SPRAG CLUTCH A **one-way sprag clutch** that consists of a hub and a drum separated by a number of figure-eight-shaped metal pieces called **sprags**. ● **SEE FIGURE 130–18**.

Sprags lock and unlock the clutch in a manner similar to the rollers in a one-way roller clutch. The shape of a sprag provides two effective working lengths. The direction the sprag tilts determines if working length is short or long.

NOTE: Some one-way clutches, either roller or sprag types, can be installed in a transmission or transaxle upside down by mistake. The transmission will not work correctly and will require that the unit be removed and disassembled again. Also check service information on how the one-way clutches should be installed.

VALVE BODY

PURPOSE AND FUNCTION A **valve body** is where most of the valves in a transmission are located and is attached to the case with bolts. Valve bodies can be either cast aluminum or cast iron. The valve body in most rear-wheel-drive transmissions is located

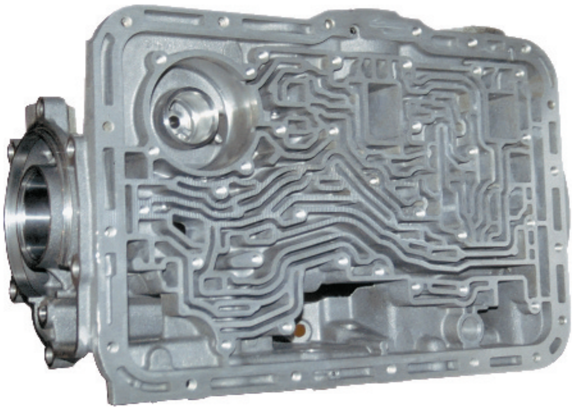

FIGURE 130–20 A typical upper valve body showing the fluid passages ("worm holes").

PARTS Valve bodies have many fluid passages for the various transmission hydraulic circuits cast into them. These are sometimes called **worm holes** or **worm tracks**. ● **SEE FIGURE 130–20.**

Some of these passages may be widened to form pockets that contain steel, nylon, or rubber check balls. Most valve bodies consist of two or more cast sections that bolt together with a flat metal separator plate between them. The upper section of the valve body is part of the transmission case casting. The **separator plate**, also called a *spacer plate,* provides rigidity and contains calibrated holes and openings that help manage fluid flow. Valve bodies contain specialized valves and circuits that are particular to a specific transmission. Electronic solenoids are used in place of some valves on electronically controlled transmissions/transaxles. Some transmissions/transaxles incorporate the TCM right on the valve body. This eliminates the wire harness between

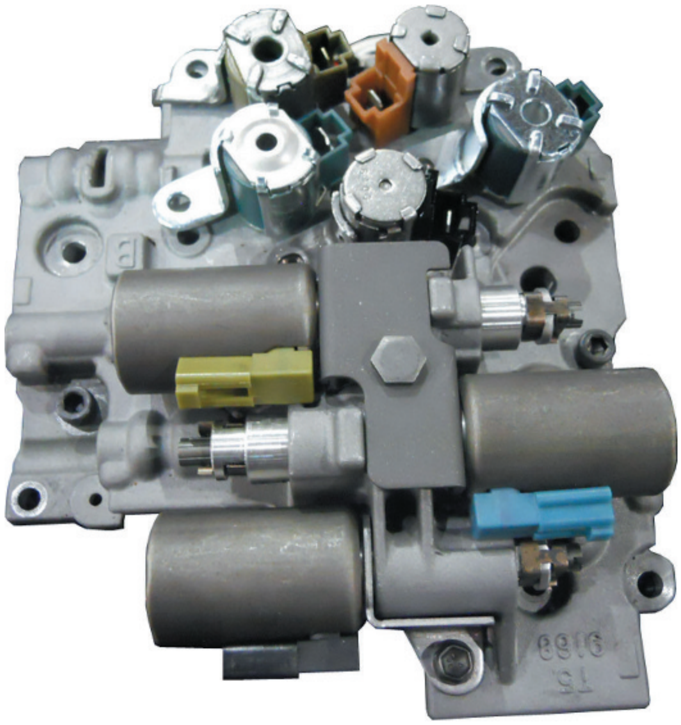

FIGURE 130–21 Electronically controlled automatic transmissions/transaxles use solenoids located in the valve body to control line pressure and to open and close passages in the valve body to control shifts.

the TCM and the solenoids, which in turn eliminates connector problems. ● **SEE FIGURE 130–21**.

FLOW-DIRECTING VALVES Flow-directing valves, or switching valves, control the direction and distribution of fluid flow in the hydraulic system. These valves may open or close passages, fill hydraulic circuits, apply or release clutches and bands, and control the direction of fluid flow from one passage or circuit to another.

ONE-WAY VALVES A **one-way valve** allows fluid to flow in one direction. The spring-loaded ball check valve is an example of a one-way valve. Valve operation is similar to that of a poppet valve. The spring holds the ball against its seat at the inlet port until fluid pressure overcomes spring force to push the ball from its seat. Fluid flows through the valve as long as hydraulic pressure exceeds the force of the spring.

Spring-loaded ball check valves are used as pressure-relief valves, and work well on bypass circuits because they provide a fast apply rate with a slow release. A second type of one-way valve is a simple gravity valve, as commonly used in transmission valve bodies.

CHECK BALLS The **check balls** in these valves are usually made of steel, but they can be nylon, rubber, or some composite material as well. The type of material used depends on the manufacturer and application. Steel balls generally hold up better, but cause greater seat wear because of their hardness. The softer composite balls are easier on seats and cannot be magnetized. ● **SEE FIGURE 130–22**.

ORIFICES Orifices are holes in the separator plate and are used for several reasons, including

- To control the rate of fluid movement and timing of clutch/accumulator application (shift feel)

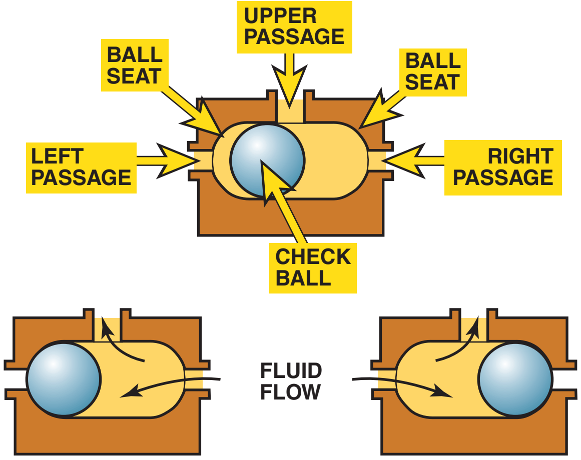

FIGURE 130–22 Check balls are used in the valve body to allow hydraulic circuits to share a common passage.

- To separate hydraulic circuits inside the transmission, so a big leak in one circuit will not cause pressures to drop in the rest of the transmission as well

MANUAL VALVE The **manual valve** is the primary flow-directing valve in an automatic transmission. This valve connects to a shift lever in the transmission, which in turn connects to the gear selector lever through a mechanical linkage. The driver controls manual valve position through the gear selector and shift linkage.

Mechanical linkage physically positions the manual valve in its bore for the particular gear range selected. The part used to position the manual valve is commonly called the “rooster comb” because of its shape. ● **SEE FIGURE 130–23**.

The manual valve receives mainline pressure from the regulated pump output and distributes it to the hydraulic circuits uncovered by the valve lands.

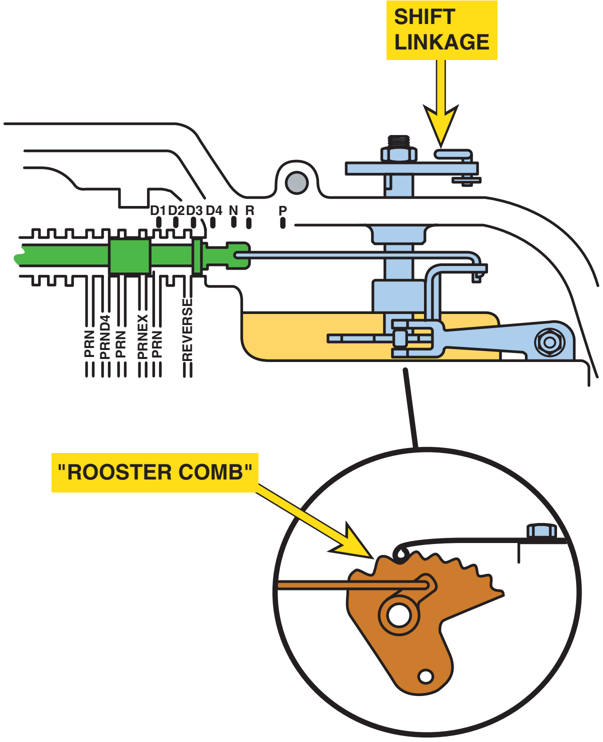

FIGURE 130–23 A rooster comb is the detent that helps retain the manual valve in the various positions in the valve body.

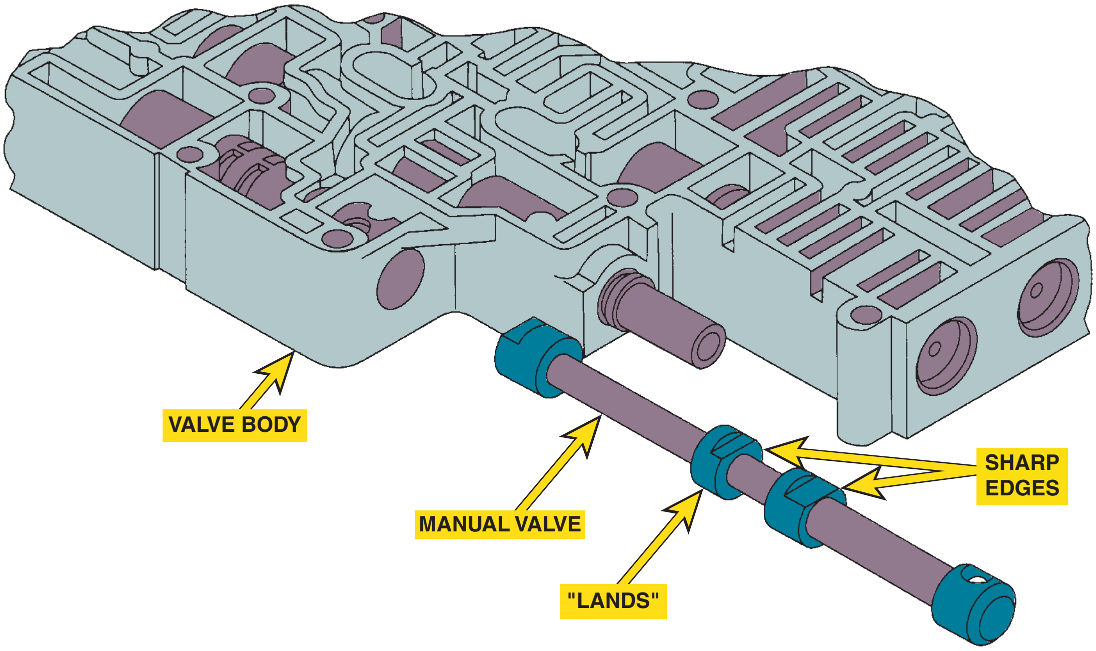

FIGURE 130–24 The manual valve is a spool valve that is moved by the shift linkage. All valves in the valve body have sharp edges on the lands. Any dirt in the valve body area can cause shifting problems due to the close tolerances between the valves and the bores in the valve body.

FREQUENTLY ASKED QUESTION

What Is a Spool Valve?

A spool valve is named after a spool of thread. A spool of thread is wooden and a spool valve used in an automatic transmission/transaxle is aluminum or steel. The ridges (larger diameter) of the spool valve fit closely into a smooth bore in the valve body and are used to direct the flow of automatic transmission fluid.

- The larger diameter sections of the spool valve are called *lands*.
- The smaller diameter sections of the valve are called *grooves or valleys*.
- The fluid is blocked by the lands and flows through the grooves or valleys. ● **SEE FIGURE 130–24**.

ELECTRONICALLY CONTROLLED TRANSMISSIONS

BACKGROUND Electronically controlled transmissions and transaxles have been used by most vehicle manufacturers since the early 1990s. Compared to hydraulically controlled units, using the powertrain control module (PCM) or the transmission control module (TCM) to operate and control shifting results in smoother operation. Also, the PCM or TCM can monitor the circuits and set a diagnostic trouble code if a fault is detected.

NOTE: All transmissions use hydraulic pressure and automatic transmission fluid to do the actual shifting. The difference between hydraulically controlled and electronically controlled automatic transmissions is the way that the shift points are controlled.

INPUTS The following are inputs to the powertrain control module (PCM) and their purposes:

- **Transmission range switch.** This sensor is used by the PCM to detect the gear being commanded by the driver. If reverse or a manual forward gear is selected, then higher line pressure will be needed and the shifts will be delayed to provide more power being delivered to the drive wheels. ● **SEE FIGURE 130–25**.
- **Engine speed.** The speed of the engine has a direct relation to the amount of power the engine is developing. The engine speed information is taken from the crankshaft position (CKP) sensor and is used by the PCM or TCM to control shift points and regulate line pressure.
- **Throttle position (TP) sensor.** This sensor is used by the PCM to detect the throttle opening being commanded by

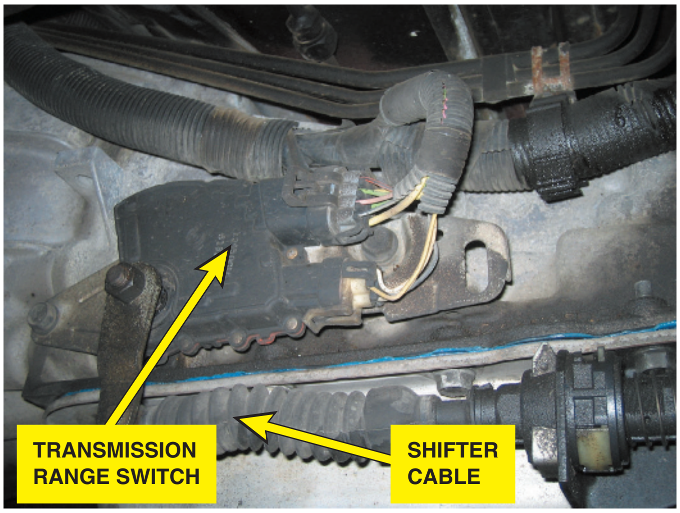

FIGURE 130–25 A transmission range switch on a rear-wheel-drive automatic transmission mounted directly to the side of the case of the unit and accessible from underneath the vehicle.

FIGURE 130–26 Speed sensors are used by the powertrain control module (PCM) or the transmission control module (TCM) to control shifts and detect faults such as slippage when the two speeds do not match the predetermined ratio for each gear commanded.

the driver. A higher throttle opening means that higher line pressure will be needed and the shifts will be delayed to provide more power being delivered to the drive wheels.

- **Manifold absolute pressure (MAP) sensor.** This sensor is used by the PCM to detect the amount of load on the engine. The greater the load, the more fuel that needs to be supplied, and the greater the amount of power the engine will create. This signal is used to determine the best shift points and regulate line pressure.
- **Mass airflow (MAF) sensor.** This sensor is used by the PCM to detect the amount of air entering the engine. The greater the amount of air, the more fuel that needs to be supplied and, therefore, the greater the amount of power the engine will create. This signal is used to determine the best shift points and regulate line pressure.
- **Speed sensors.** These sensors measure the speed of the input shaft and output shaft or sometimes other shaft speeds in the automatic transmission or transaxle. The output shaft speed sensor is often used to provide vehicle speed information to the PCM and for adaptive learning and self-diagnosis. ● **SEE FIGURE 130–26**.
- **Transmission fluid temperature (TFT) sensor.** This sensor is used by the PCM or TCM to detect the temperature of the automatic transmission fluid. This signal is used to determine the best shift points and regulate line pressure. It will cause the PCM or the TCM to engage the torque converter clutch (TCC) sooner and disable overdrive, to help reduce the fluid temperature if it reaches higher than normal.

OUTPUTS Outputs to the powertrain control module (PCM) or transmission control module (TCM) and their purposes include the following:

- **Pressure control.** The PCM or TCM controls the line pressure by changing the signal to the pressure control solenoid. Using the input signal to detect the conditions that the vehicle is being driven, the specified line pressure is commanded to provide smooth shifts without slippage.

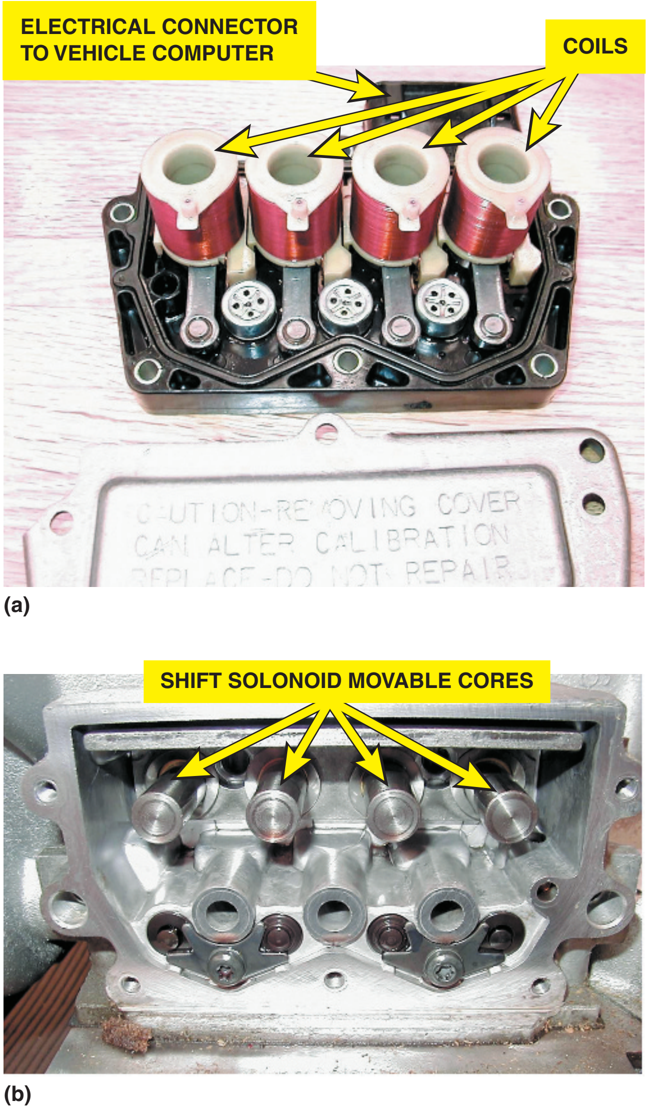

FIGURE 130-27 (a) An example the shift solenoids installed in a valve body assembly, showing the coils and (b) the solenoid cores.

- **Shift control solenoids.** The PCM or TCM controls the shifting by applying power or ground to the correct control solenoid(s) at the right time. ● **SEE FIGURE 130–27**.
- **Torque converter clutch (TCC).** The PCM or TCM controls the application of the torque converter clutch (TCC) by applying power or ground to the correct control solenoid at the right time.

ADAPTIVE LEARNING Most late model electronically controlled automatic transmissions/transaxles use the PCM or TCM to monitor the time it takes to complete a shift. The PCM can determine this from the comparison between the engine speed and the output speed sensor data. When a shift is commanded, there should be a change in the speed of the output shaft. If the change in speed is longer than normal, which could indicate normal wear in the clutch pack, the PCM can learn from this and start the shift sooner to allow time for the clutch to be fully engaged.

SHIFT SOLENOIDS Solenoids used in electronically controlled automatic transmissions/transaxles are

- **On-off solenoids.** These can be normally open to fluid flow or normally closed to block fluid flow.

They are commanded on or off by the PCM or TCM. The resistance of most on-off shift solenoids is 10 to 15 ohms.

- **Linear solenoids.** This type of solenoid can be varied by changing the amount of on time to precisely control the fluid flow through the solenoid valve. The variable power or ground applied to the linear solenoids is pulse-width modulated (PWM) and allows the PCM precise control over the shifting and the fluid pressure. The resistance of most linear (PWM) shift solenoids is about half of the on-off type and ranges from 4 to 6 ohms.

Shift solenoids control the pressure force, which in turn controls the position of the shift valve. Shift solenoids may be labeled 1 and 2 or A and B. Using a combination of the two shift solenoids prevents the actuation of four forward gears.

A **default** (or **limp-in**) **gear** is the forward speed that is used if there is a failure in the electronic or computer system. If neither solenoid is engaged, then either second or third gear is actuated, depending on the exact make and model of the transmission or transaxle. ● **SEE CHARTS 130–1 AND 130–2** for examples of two General Motors transmissions.

TECH TIP

Parking Brake before Parking Pawl

To prevent possible damage to the transmission/transaxle case or other internal components, most experts agree that the parking brake should be applied *before* placing the gear selector into the park position, especially when parking on a hill. This procedure keeps the weight of the vehicle from being exerted entirely on the parking pawl and makes it easier to move the gear selector out of the park position.

TYPICAL TORQUE FLOW

The General Motors 4L60-E can provide an example of how a typical electronically controlled rear-wheel-drive automatic transmission works. ● **SEE CHART 130–3**.

reaction carrier stationary, but torque input to the gear set stops at the input housing.

The torque converter housing and impeller rotate clockwise at engine speed to hydraulically drive the turbine and mechanically drive the oil pump. The transmission input drum assembly rotates clockwise at turbine speed to drive the gear set. Turbine speed is slightly less than engine crankshaft speed. However, there is nothing connecting the input drum assembly to drive the gear sets and transfer torque at this time.

In neutral, the output shaft is free to rotate in either direction, and the vehicle can be pushed or towed. However, use caution because if the engine is not running, the pump is not providing lube fluid to components. In park, a mechanical pawl or finger engages one of many large notches cut into a gear mounted on the output shaft, preventing the vehicle from moving in either direction.

OVERDRIVE FIRST With the gear selector lever in overdrive, the transmission starts off in first gear, and then upshifts into second, third, and fourth gears as the vehicle continues to accelerate. To engage first gear, the forward clutch applies, transferring engine torque from the input shaft to the input sun gear through the forward sprag clutch, driving the sun gear clockwise.

With the input sun gear turning clockwise, the input pinion gears spin counterclockwise in the stationary carrier and attempt to drive the input ring (internal) gear and reaction carrier counterclockwise. However, the forward sprag clutch is holding, so the pinions walk clockwise inside the ring (internal) gear, turning the input carrier clockwise. Then, the input carrier drives the output shaft clockwise in gear reduction. ● **SEE FIGURE 130–28**.

The reaction ring (internal) gear turns clockwise along with the output shaft and drives the reaction pinions clockwise on the stationary reaction carrier assembly. Pinion action drives the reaction sun gear counterclockwise. However, the reaction sun gear is not connected to a gear set member, so the reaction gear set simply freewheels. The low roller clutch prevents the reaction carrier from turning counterclockwise.

As long as the vehicle continues to accelerate in overdrive first, torque transfers through the gear set to the output shaft. During closed-throttle coasting, the clockwise torque load on the forward sprag clutch and the counterclockwise torque load on the low roller clutch are released. Both one-way clutches overrun so the gear sets freewheel on deceleration, and engine braking is not available.

OVERDRIVE SECOND As the vehicle continues to accelerate in the overdrive range, the transmission upshifts to second gear by applying the 2-4 band. The band holds the reverse drum, input shell, and reaction sun gear stationary. The forward clutch remains applied, while the input shaft drives the input sun gear clockwise through the forward sprag clutch. ● **SEE FIGURE 130–29**.

As in first gear, the input sun gear rotates clockwise and drives the input pinions counterclockwise. Since the 2-4 band is holding, the input pinions walk inside the internal gear, driving the input carrier and output shaft clockwise in gear reduction.

At the same time, the output shaft drives the reaction internal ring gear and pinion gears clockwise. With the reaction sun gear held, the pinion gears walk clockwise and drive the reaction carrier clockwise with them.

Clockwise rotation of the reaction carrier transfers to the input ring (internal) gear through the reaction carrier shaft. With the input ring (internal) gear turning clockwise, the input pinions spin counterclockwise and drive the input carrier clockwise. This removes the counterclockwise torque load from the low roller clutch so that it overruns at this time. There is no engine compression braking available in overdrive second because the forward sprag clutch overruns.

OVERDRIVE THIRD To automatically upshift into third gear as the vehicle continues to accelerate, the transmission releases the 2-4 band and applies the 3-4 clutch. Also, the forward clutch remains applied so the input shaft drives the input sun gear clockwise through the forward sprag clutch. ● **SEE FIGURE 130–30**.

Applying the 3-4 clutch connects the input shaft to the input ring (internal) gear, which drives the ring (internal) gear clockwise at turbine speed. Now that two members of the input gear set—the sun and ring (internal)—are being driven at turbine speed, the gear set provides direct drive as it locks up and turns as a unit.

As long as the vehicle is accelerating in overdrive third, torque transfers through the planetary gear set to the output

shaft. There is no engine braking because the forward one-way clutch overruns and allows the input sun gear to freewheel.

OVERDRIVE FOURTH The transmission upshifts into fourth gear by applying the 2-4 band as the vehicle continues to accelerate in overdrive range. The 2-4 band holds the reverse drum and reaction sun gear stationary. Both the 3-4 and forward clutches remain applied, and the input drum continues to drive the input ring (internal) gear clockwise. ● **SEE FIGURE 130–31**.

This drives the reaction carrier clockwise as well, since it is in common with the input ring (internal) gear. As the carrier turns, the reaction pinions walk clockwise around the stationary reaction sun gear. This drives the reaction ring (internal) gear and output shaft clockwise at an overdrive ratio.

In fourth gear, the input ring (internal) gear turns at input shaft speed, while the input carrier turns at a faster output shaft speed; both gears turn clockwise. As a result, the input pinions turn counterclockwise and drive the sun gear clockwise faster than input speed. This causes the forward sprag clutch to overrun and renders the forward friction clutch, which remains applied, ineffective.

When the transmission is operating in fourth gear, the input member, the reaction carrier, is being driven by a multiple-plate clutch, while a band prevents the held member, the reaction sun gear, from turning in either direction. Therefore, engine compression braking is available. However, due to the overdrive gear ratio, the braking effect is not noticeable to the driver.

REVERSE With the gear selector lever in reverse, the low-reverse clutch applies to drive the reaction sun gear clockwise with the input shaft. The reaction carrier and input ring (internal) gear are held stationary by the applied reverse input clutch. This turns the reaction pinions counterclockwise and drives the carrier counterclockwise in gear reduction. ● **SEE FIGURE 130–32**.

In reverse gear, the input ring (internal) gear is held, while the input carrier is driven counterclockwise. This causes the input pinions to rotate clockwise and drive the input sun gear counterclockwise.

TRANSMISSIONS AND TRANSAXLES

POWERTRAIN CONFIGURATION In rear-wheel-drive (RWD) applications, it is most common to use a transmission along with a driveshaft and differential at the rear axle to transmit torque to the drive wheels. The Lexus GS450h and LS600h are both examples of rear-wheel-drive hybrid electric vehicles. The Ford Mustang Mach-E standard configuration is an example of a rear-wheel-drive electric vehicle. In a front-wheel-drive (FWD) vehicle, a transaxle assembly is used with half-shafts to transmit torque to the drive wheels. A transaxle is the combination of a transmission, differential, and final drive gears built together as one assembly. A Toyota Prius and Hyundai Sonata hybrid are examples of FWD hybrid vehicles. The Chevrolet Bolt is an example of an FWD electric vehicle. ● **SEE FIGURE 131–1**.

In a four-wheel-drive (4WD) or all-wheel-drive (AWD) vehicle, a transfer case or rear electric motor is used to distribute power to all four wheels. The Toyota Highlander/Lexus RX450h uses a transaxle on the front of the vehicle and an electric motor to drive the rear wheels in the 4WD model. The 4WD version of the Ford Escape hybrid uses a separate power takeoff (PTO) from the transaxle to mechanically drive the rear axle.

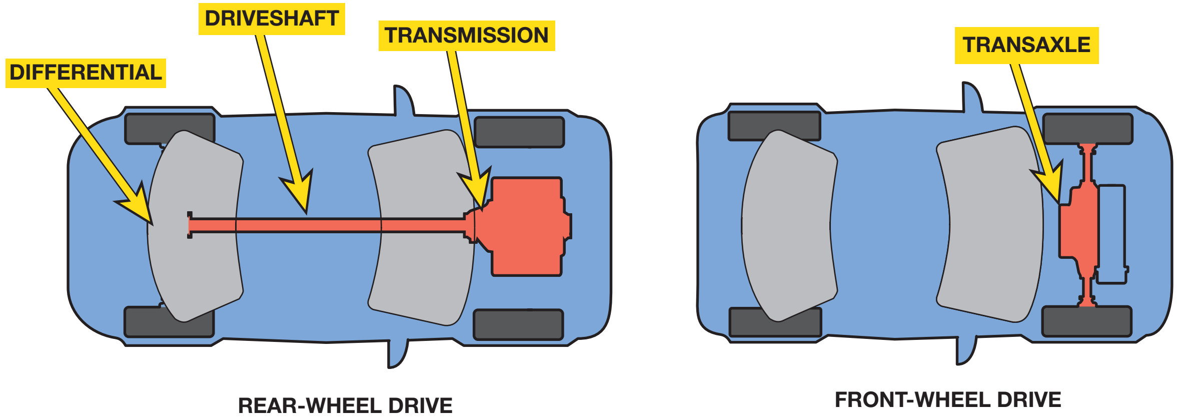

FIGURE 131–1 Rear-wheel-drive (RWD) vehicles use transmissions to send torque to the rear differential and final drive. Front-wheel-drive (FWD) vehicles use a transaxle, which incorporates the differential and final drive into the transaxle case.

PRINCIPLES INVOLVED

TORQUE DELIVERY To move a vehicle, torque must be applied to the drive wheels. **Torque** is *twisting force.*

Torque is applied to the drive wheels to make the vehicle accelerate. The vehicle transmission is responsible for increasing engine torque in the lower speed ranges when acceleration is required, and then reducing engine speed for the best fuel economy when the vehicle is cruising. Internal combustion engines (ICEs) are very different from electric motors in that they only produce torque in a relatively narrow RPM range. ● **SEE FIGURE 131–2**.

An ICE is most efficient when it is operating near its torque peak. This is the RPM when the engine is breathing most efficiently, and is typically where the engine can deliver the best fuel economy. However, it is difficult to keep the engine in this range during all phases of vehicle operation. Automotive engineers overcome this difficulty in two ways:

1. By increasing the RPM range where the engine produces torque ("flattening" the torque curve).
2. By increasing the number of gear ratios in the transmission.

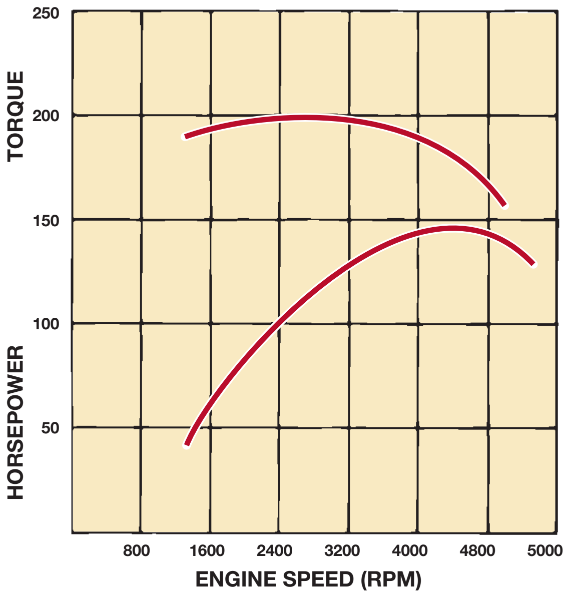

FIGURE 131–2 Graph showing engine torque vs. horsepower output for a typical internal combustion engine. ICEs produce maximum torque at a high RPM, whereas electric motors produce maximum torque at low RPM.

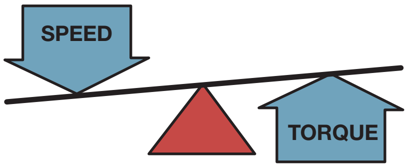

FIGURE 131–3 When output speed decreases in a transmission, output torque will increase.

With more transmission ratios, it is easier to match the vehicle road speed with the most efficient engine RPM. Therefore, any torque increase is generated at the expense of speed. In other words, when torque is increased in a transmission, output speed is decreased. ● **SEE FIGURE 131–3**.

MULTIPLE SPEED TRANSMISSIONS/TRANSAXLES Years ago, it was common for vehicles with automatic transmissions to have only 2, 3, or 4 gear ratios. Currently, 5-, 6-, 7-, 8-, and 10-speed automatic transmissions are becoming common. With more emphasis being placed on fuel economy and lower emissions, the continuously variable transmission (CVT) is becoming more popular as it provides infinite gear ratios and the best opportunity to maximize engine efficiency.

HEV TRANSMISSIONS

CLASSIFICATIONS HEV transmissions are different based on the level of the hybrid vehicle in which they are installed. A mild hybrid with stop-start system typically contains a transmission with a single electric motor. A full hybrid generally contains a transmission with two electric motors.

ELECTRIC AUXILIARY PUMP In order to adapt a conventional automatic transmission to a hybrid powertrain, an **electric auxiliary pump** is used to maintain fluid pressure in the transmission during ICE idle-stop. This pump is powered by a DC brushless (AC synchronous) motor, which requires a special controller to provide the correct operating frequency and pulse width. When the auxiliary pump is operating, it sends hydraulic pressure to the transmission regulator valve, and on to the manual valve where it is directed to the appropriate clutches. This prevents the transmission from shifting into "neutral" when the ICE is in idle-stop. Once the ICE restarts, the auxiliary pump is turned off and hydraulic pressure is again supplied by the mechanically driven transmission fluid pump. ● **SEE FIGURE 131–4**.

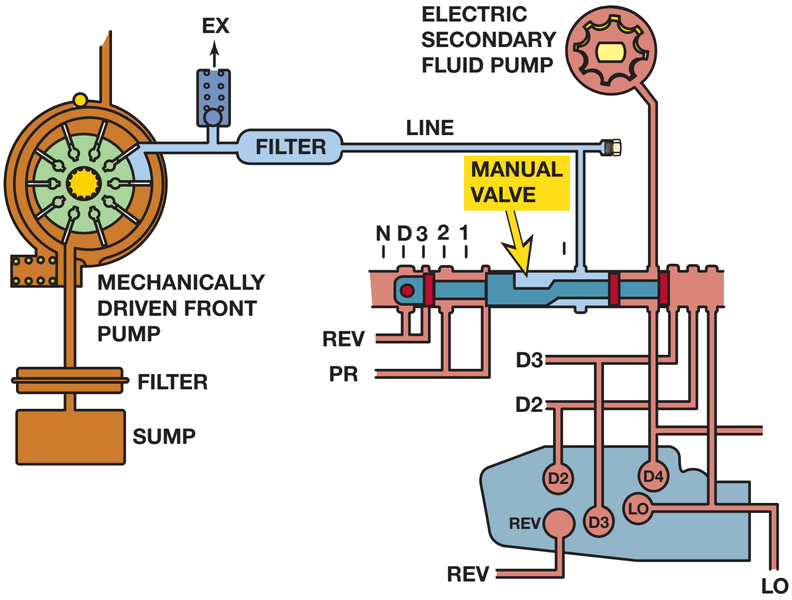

FIGURE 131–4 The hydraulic circuit diagram for this GM transmission includes a mechanical pump and an electric secondary fluid pump.

HYDRAULIC IMPULSE STORAGE ACCUMULATOR A **hydraulic impulse storage accumulator** is used to provide fluid pressure as the ICE restarts after the idle-stop mode. During normal engine operation, the mechanical transmission pump provides the hydraulic pressure and charges the accumulator. When the engine restarts, the accumulator provides the initial hydraulic pressure and the mechanical pump provides the continuation of the pressure. The pressure release from the accumulator ensures there is no delay in acceleration, and it eliminates the need for an electric auxiliary pump. ● **SEE FIGURE 131–5**.

GM PARALLEL HYBRID TRUCK (PHT)

DESCRIPTION The transmission in the 2004–2008 Chevrolet Silverado/GMC Sierra parallel hybrid truck (PHT) is based on the 4L60E electronically controlled automatic transmission design with minor modification to adjust for its new role in a hybrid powertrain. It has four forward speeds and one reverse, with the fourth speed being an overdrive. It is designed primarily for medium- and large-displacement engines and is used extensively in GM pickups and SUVs. The specific model used in the hybrid pickup is known as the M33.

OPERATION In idle-stop mode the engine stops, which will in turn stop the transmission oil pump and cause the transmission to go to "neutral." To prevent this, an electric secondary fluid pump is installed on the valve body inside the transmission oil pan. Whenever the engine goes into idle-stop, the electric fluid pump is turned on to maintain oil pressure on the transmission forward clutch and keep the drivetrain connected to the engine. This results in a smoother transition between idle-stop and engine restarting as the vehicle resumes operation. ● **SEE FIGURE 131–6**.

The conventional 4L60E transmission is made to allow the vehicle to coast or brake without any interference from the engine. To enable regenerative braking, the hybrid version of the 4L60E transmission is made to apply the overrun clutch during coast or braking in the D4 range and either third or second gear. This allows power to be transmitted back through the torque converter, which can then be used to generate electric current for recharging the 42-volt battery pack.

SERVICE Transmission service for the 4L60E model M33 is limited to fluid and filter changes. This transmission requires Dexron VI fluid. The filter on the electric secondary fluid pump is replaceable, but is not a regular maintenance item. Transmission pressure testing can be performed using the line pressure tap located on the transmission case. These tests are most often done by attaching a pressure gauge to the fitting on the side of the transmission and operating the transmission under various load conditions and road speeds. The test results are recorded and compared to charts to help determine what area(s) of the transmission might be malfunctioning.

A scan tool can be used to access DTCs (diagnostic trouble codes) and also to perform bidirectional testing of the transmission

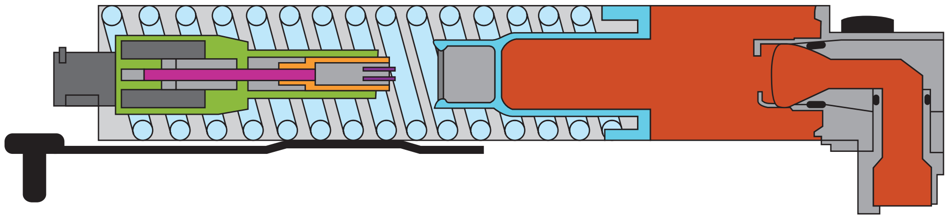

FIGURE 131–5 When the solenoid is energized, the accumulator releases the fluid creating the initial pressure needed at restart.

solenoids. A scan tool can also be used for clearing the *transmission adaptive pressure* (*TAP*) values if any of the following has occurred:

1. If the transmission has been overhauled or replaced.
2. Repair or replacement of an apply or release component (band, clutch, servo, piston, etc.).
3. Repair or replacement of a component that directly affects line pressure.

GM TWO-MODE HYBRID TRANSMISSION

DESCRIPTION The two-mode hybrid transmission used in 2009–2013 General Motors hybrid trucks is labeled a 2ML70. This unit features two 60-kW motors in the hybrid drivetrain, a 300-volt battery pack, and a V8 engine. A two-mode hybrid electric vehicle can increase the fuel economy by about 25%, depending on the type of driving conditions. Like all hybrids, the two-mode combines the power of a gasoline engine with that of electric motors and includes the following:

- Regenerative braking that captures kinetic energy that would otherwise be lost
- Idle-stop

Some full-hybrid systems have a single mode of operation, using a single planetary gear set to split engine power to drive the wheels or charge the battery. These systems are effective at low speeds because they can move the vehicle without running the gasoline engine (ICE). But at higher speeds, when the engine is needed, using the electric motors has much less benefit. As a result, sending power through electric motors and a variable transmission is roughly 20% less efficient than driving the vehicle through a purely mechanical power path, using gears.

COMPONENTS The two-mode unit is effectively an electronically variable transmission (EVT). It includes three simple planetary gear sets with four multiplate clutches. It has four fixed gear ratios with two EV ratios for smooth, more efficient operation. The components of the two-mode transmission include the following:

- Two 60-kW electric motor/generators assemblies.
- Three planetary gear sets (one is located in front of motor/generator A, called M/G A; another is located between the two motor/generators; and the last planetary gear set is located behind motor/generator B, called M/G B).
- Four wet plate clutches (two friction [rotating] and two [reaction/stationary] clutch assemblies). ● **SEE FIGURE 131–7.**

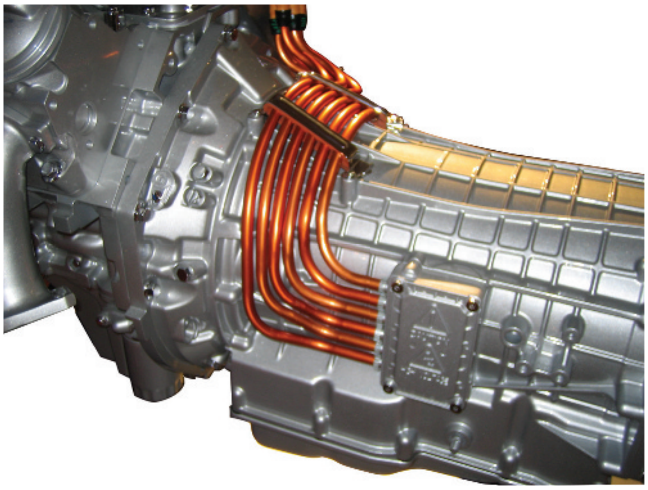

FIGURE 131–7 The two-mode transmission has orange high-voltage cables entering the unit to carry electric energy from the high-voltage battery pack to propel the vehicle and also charge the battery during deceleration.

The vehicle starts moving in EV 1 with a variable ratio from infinite low to 1.7:1. If the vehicle is launched with the engine off, M/G A will spin the engine crankshaft so it can start running. EV 2 has a ratio between 1.7:1 and 0.5:1.

FIRST MODE OF OPERATION The first mode is for accelerating from standstill to second gear. At low speed and light load, the vehicle can be propelled by

- Either electric motor alone
- The ICE alone
- Or a combination of the two (electric motor and/or ICE)

In this mode, the engine (if running) can be shut off under certain conditions and everything will continue to operate on electric power alone. The hybrid system can restart the ICE at any time as needed. One of the motor/generators operates as a generator to charge the high-voltage battery, and the other works as a motor to assist in propelling the vehicle.

SECOND MODE OF OPERATION The second mode takes the vehicle from second gear through to overdrive. At higher loads and speeds, the ICE always runs. In the second mode, the motor/generators and planetary gear sets are used to keep torque and horsepower at a maximum. As the vehicle speed increases, various combinations of the four fixed ratio planetary gears engage and/or disengage to multiply engine torque, and allowing one or the other of the motor/generators to perform as a generator to charge the high-voltage battery. ● **SEE FIGURE 131–8.**

TWO-MODE SERVICE Routine service is all that is needed or required of the two-mode transmission. Fluid-level check and visual inspection should be all that is required until the first scheduled fluid change. Always use Dexron VI. Faults in the system will often set a diagnostic trouble code. Unit repair of the unit requires an engine hoist or the lift arm of a vehicle lift to remove the motor assembly. ● **SEE FIGURE 131–9 A AND B.**

FORD/LINCOLN 10R80 MHT

DESCRIPTION The 10R80 MHT is a modular ten-speed hybrid transmission that was introduced in the 2020 Explorer and the 2020 Lincoln Aviator plug-in hybrid. The transmission is unique because unlike most hybrid transmissions it still uses a torque converter. The continued use of the torque converter improves towing and hauling capabilities. An electric motor and disconnect clutch are placed between the engine and the torque converter. In addition to providing stop-start capabilities, the electric motor provides low-speed torque and additional power. The MTH transmission is six inches longer than the non-hybrid model (10R80) and shares 90% of the same components. ● **SEE FIGURE 131–10 A AND B.**

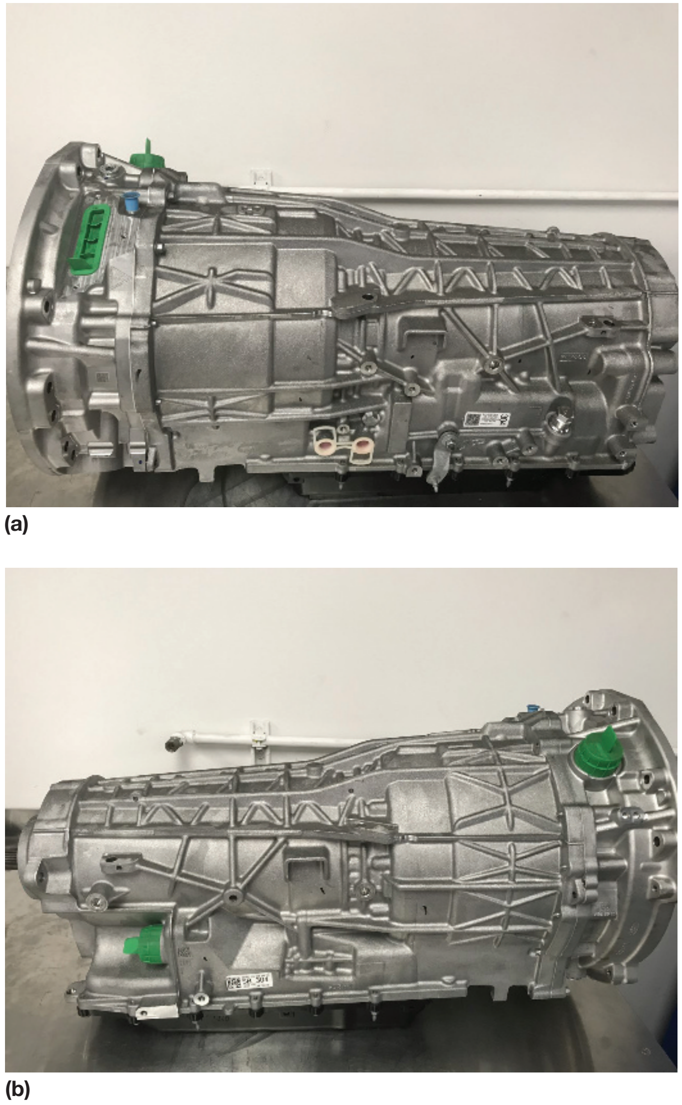

FIGURE 131–10 (a) The driver side of the transmission contains the high-voltage connections and the shift level assembly. The hybrid portion of the transmission is forward of the gasket. (b) The passenger side of the transmission contains the low-voltage connections.

COMPONENTS The components of the hybrid drive unit of the transmission are as follows:

- Electric motor
- Resolver (speed sensor)
- High-voltage connection
- Low-voltage connection

The hybrid drive unit is removed from the transmission as a unit. An engine hoist and special adapter are recommended when completing this task because of the weight of the unit. ● **SEE FIGURE 131–11 A AND B.**

The electric motor is a permanent magnet three-phase motor that generates 33 kW of power. ● **SEE FIGURE 131–12 A AND B.**

The resolver (speed sensor) provides the powertrain control module (PCM) with the speed, location, and direction of rotation of the electric motor. ● **SEE FIGURE 131–13.**

The high-voltage connector at the transmission allows the electric motor in the hybrid section of the transmission to be connected to the Inverter System Controller (ISC) via the orange-colored high-voltage insulated wiring. ● **SEE FIGURE 131–14.**

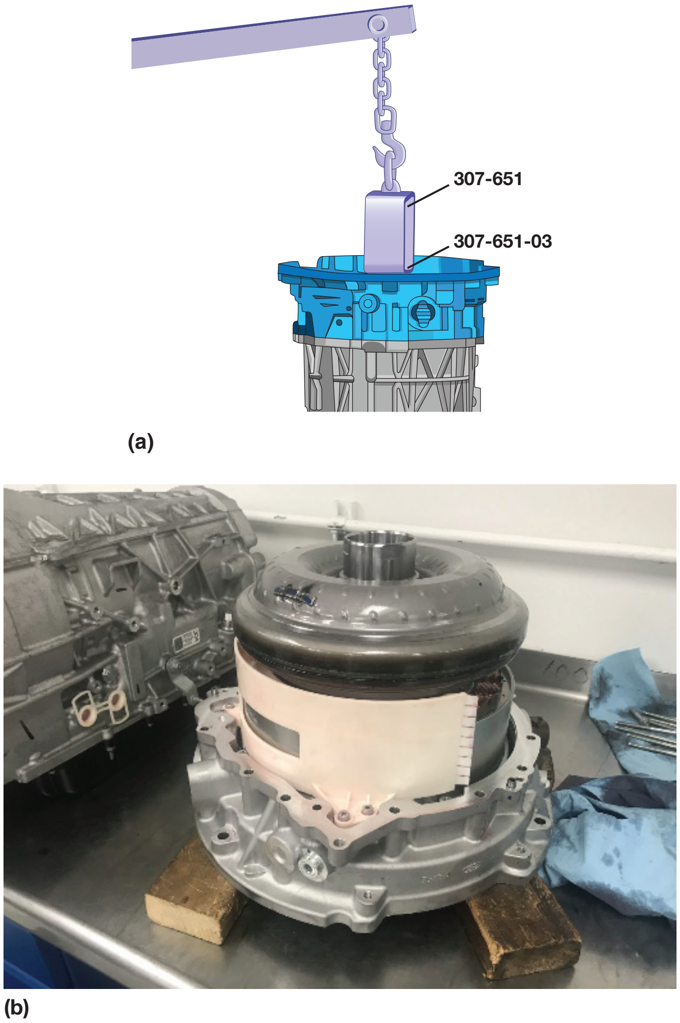

FIGURE 131–11 (a) An engine hoist and adapter are used to remove the hybrid portion of the transmission. (b) The hybrid portion of the transmission resting on two wooden blocks after being removed from the transmission.

The low-voltage connectors at the transmission provide for traditional transmission control and monitoring by the powertrain control module. ● **SEE FIGURE 131–15.**

SERVICE Service procedures performed at specific service intervals include the transmission fluid and filter. If the non-hybrid section of the transmission experiences a failure, a detailed overhaul procedure is provided. If the hybrid section of the transmission experiences a failure, it is replaced as a unit. Most electrical components, such as solenoids and sensors, are monitored by the powertrain control module (PCM) and supported with specific diagnostics related to a diagnostic trouble code (DTC). The external electrical components are serviceable.

TOYOTA/LEXUS POWER-SPLIT SYSTEM

DESCRIPTION The power-split transaxle is a series-parallel hybrid technology. During most phases of vehicle operation, the system is operating as both series and parallel at the same time. While the control system is complex, the basic transaxle is very simple in design as it is built around a single planetary gear set (power-split device) and two electric motor/generators, called MG1 and MG2. ● **SEE FIGURE 131–16**.

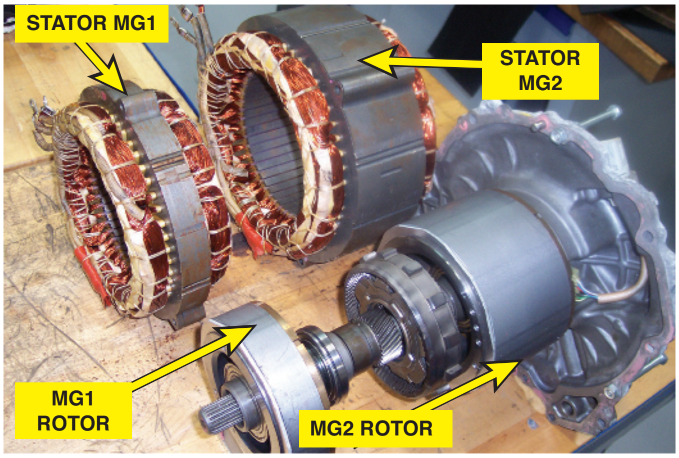

FIGURE 131–16 The Toyota Hybrid System uses two electric motor/generators (MG1 and MG2) and an ICE connected together by a power-split device, which is a simple planetary gear set.

A planetary gear set is composed of three main components:

1. Ring gear
2. Planet carrier
3. Sun gear

In the power-split transaxle, a large electric motor/generator (MG2) is directly attached to the transaxle final drive and the planetary ring gear. The ICE is connected to the planet carrier, and the small electric motor/generator (MG1) is connected to the sun gear. ● **SEE FIGURE 131–17**.

The planetary ring gear always turns in the same direction as the drive wheels and its speed is directly proportional to vehicle speed. In other words, if the ring gear is not moving, the vehicle is not moving. The power-split device is so named because the ICE (attached to the planet carrier) splits its torque output between the sun gear (MG1) and the ring gear (MG2 and drive wheels).

The gear ratio of the planetary gear set causes the ICE to send 72% of its torque to the ring gear and the remaining 28% to the sun gear. The torque split percentages remain the same regardless of what mode the transaxle is operating in because they are determined by the number of teeth on the planetary ring gear and the sun gear. ● **SEE FIGURE 131–18**.

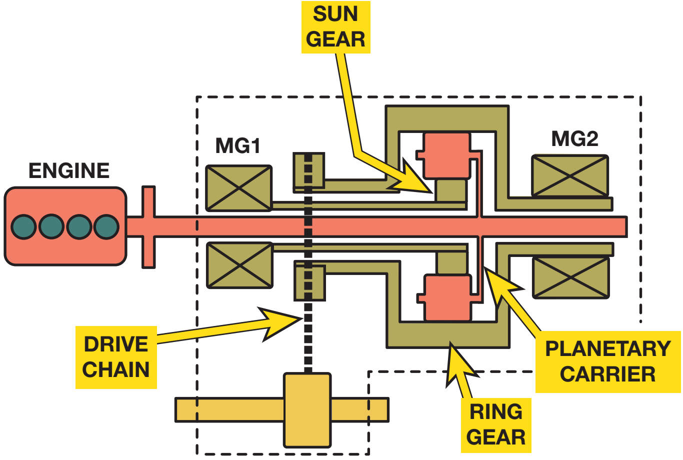

FIGURE 131–17 The power-split device from the Toyota Hybrid System. Note the vehicle will only move when MG2 (and the ring gear) is turning.

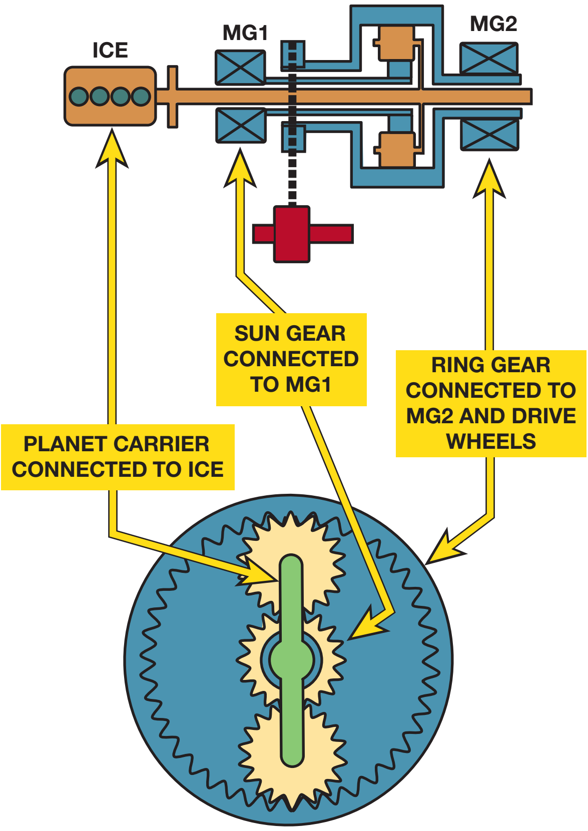

ICE

MG2
SUN GEAR CONNECTED TO MG1
RING GEAR CONNECTED TO MG2 AND DRIVE WHEELS
PLANET CARRIER CONNECTED TO ICE

FIGURE 131–18 The planetary gearset used in the Toyota Hybrid System has 2.6 times the number of teeth in its ring gear as it has in its sun gear. This means that the ICE (attached to the planet carrier) will send 72% of its torque to the ring gear (drive wheels) and 28% of its torque to the sun gear (MG1).

While torque split percentages are always the same, power split percentages will vary depending on the RPM of the various components. Horsepower is the rate at which work is performed and is a function of torque and RPM. If a shaft has torque applied to it, but remains at zero RPM, no work is being performed and no horsepower is transmitted through the shaft. The same principle applies to the torque split planetary gear set. If the sun gear is stationary, it will still receive 28% of the torque of the ICE, but all of the engine horsepower will be directed through the ring gear and on to the drive wheels.

OPERATION

- **Vehicle Stopped**. When the vehicle is stopped, nothing is happening within the vehicle drive system. The ICE is shut off, and both electric motor/generators are shut off as well. There are circuits within the vehicle that will use electrical energy from the auxiliary battery, but the drive system itself is effectively inert. The Toyota hybrid system does not use an auxiliary starter, but instead uses the MG1 for starting under all conditions. ● **SEE FIGURE 131–19**.
- **Light Acceleration**. When the vehicle is driven at low speeds and light acceleration, it is driven by MG2 alone. ● **SEE FIGURE 131–20**. This is because the electric motor is more efficient than the ICE at low vehicle speeds. Current from the high-voltage (HV) battery is sent through the inverter and on to MG2 to move the vehicle. A special graph, known as a monograph, shows the speed relationship between the various elements. When the engine is stopped (0 RPM), MG2 is turning forward (+), and this causes MG1 to turn backward (–). ● **SEE FIGURE 131–21**.

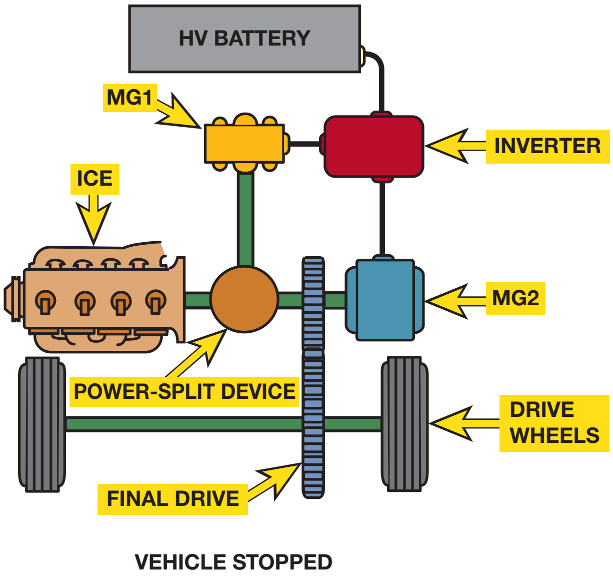

FIGURE 131–19 When the vehicle is stopped, the ICE is shut off along with both motor/generators.

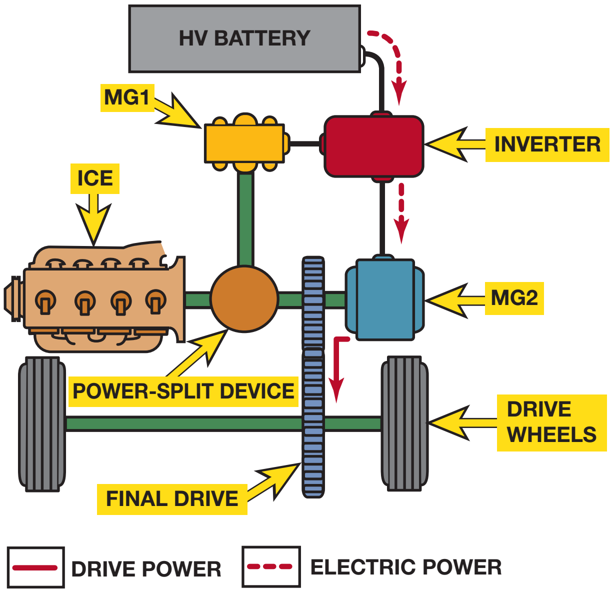

FIGURE 131–20 Under light acceleration, power is sent to MG2 to move the vehicle.

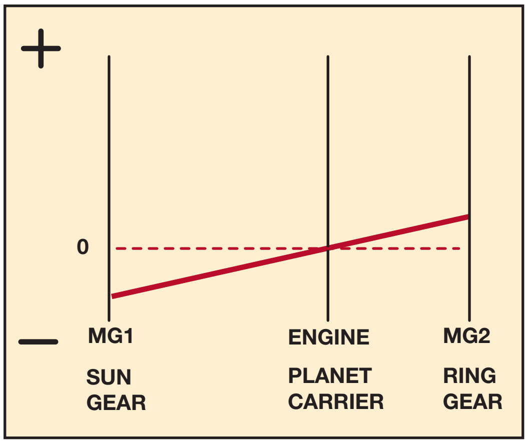

FIGURE 17–21 Under light acceleration, the engine is stopped (0 RPM), MG2 is turning forward (+), and MG1 is turning backward (–).

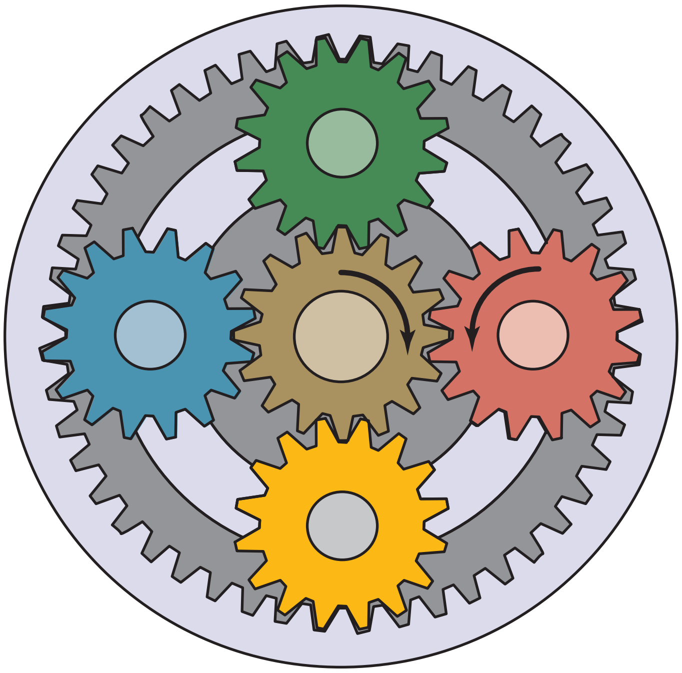

FIGURE 131–22 To start the ICE, MG1 (sun) acts as a motor and turns clockwise (CW), causing the planet carrier (attached to the ICE) to also turn CW.

- **Normal Driving**. When higher vehicle speeds are required, the ICE must be started so that its output can be combined with that of MG2. The ring gear is already turning clockwise as the vehicle travels in a forward direction. Since the planet carrier (attached to the ICE) is stationary, the sun gear (driven by MG1) is used to drive the planet carrier clockwise and start the ICE. Current from the HV battery is directed through the inverter and operates MG1 as a motor, turning clockwise and spinning the ICE up to 1000 RPM for starting. ● **SEE FIGURE 131–22**.

Once the ICE is started, MG1 operates as a generator, but turns in the counterclockwise direction. ICE output is now divided or "split" between the drive wheels (ring gear) and MG1 (sun gear). Power generated by MG1 is either directed to MG2 to help move the vehicle or is used to recharge the HV battery, if necessary. ● **SEE FIGURES 131–23 AND 131–24**.

- **Full-Throttle Acceleration and High-Speed Cruise**. When greater acceleration is required, both MG2 and the ICE continue sending torque to the vehicle drive wheels, but MG2 can also receive power from the HV battery to increase its output. As demand increases further, the ICE speed is increased for more output. To enable an increase in ICE speed, the sun gear (MG1) must rotate in a clockwise direction. It is during these times that MG1 can be configured as a motor and will draw power from MG2 during a phase known as *energy recirculation*. ● **SEE FIGURES 131–25 AND 131–26**.
- **Deceleration and Braking**. As the vehicle is decelerating, MG2 is configured as a generator. The kinetic energy (energy of movement) of the vehicle is converted into electrical energy by MG2. The ICE and MG1 are shut off, and current from MG2 is sent through the inverter and is used to recharge the HV battery. ● **SEE FIGURE 131–27**.
- **Reverse**. If reverse is selected, power is sent from the HV battery to the inverter and on to MG2. MG2 operates in

FIGURE 131–23 Normal driving—the ICE is now running and some of its torque is used to drive MG1. Electricity generated by MG1 is used to power MG2 or recharge the HV battery.

the reverse direction to back up the vehicle, but the other components in the drive system are turned off at this time. The ICE does not run when the vehicle is being driven in reverse. ● **SEE FIGURE 131–28**.

CONSTRUCTION The Toyota power-split transaxle is built with an aluminum case composed of two major assemblies. These are known as the MG1 assembly and the MG2 assembly, and each houses its respective motor/generator.

Each of the motors/generators performs two functions:

- MG1—Used to crank the ICE and generate electrical current to charge the high-voltage battery.
- MG2—Used to propel the vehicle and to charge the high-voltage battery during deceleration.

Each of these major assemblies has its own water jacket for cooling the motor/generator windings in the housing. There are two water jacket unions installed in each major assembly, and these send coolant to the motors from the separate inverter cooling system. ● **SEE FIGURE 131–29 A AND B**.

The following components are assembled on a common axis:

- Internal combustion engine (ICE)
- MG1
- Power-split device
- MG2
- Oil pump

The final drive is housed between the two major assemblies and utilizes a conventional open differential for sending torque to the front-drive wheels. A chain drive attaches the ring gear of the power-split device to the counter drive gear, which drives the counter driven gear that is meshed with the ring gear of the differential assembly. ● **SEE FIGURE 131–30**.

This system does not use a conventional clutch or torque converter. With this design, there is no need to disconnect the engine from the input shaft. This is because the engine can turn at any speed while the vehicle is stopped (ring gear is stopped) by using MG1 (sun gear) as a generator. The ICE is connected directly to the transaxle input shaft using a damper disc mechanism. ● **SEE FIGURE 131–31**.

The transaxle oil pump is housed in the rear of the MG2 assembly and is attached to the input shaft from the ICE. ● **SEE FIGURE 131–32**. The oil is circulated by the pump only when the ICE is running.

When the vehicle is driven by MG2 only, the transaxle is splash-lubricated by the movement of the final drive gears. The transaxle for the 2001–2003 Prius has a cable-operated parking lock mechanism. This was replaced with an electrically actuated mechanism starting with the 2004 model year. ● **SEE FIGURE 131–33**.

the inverter (high-voltage) system. There are drain plugs for both at the bottom of the transaxle assembly. The transaxle oil is refilled through a hole in the front of the case, with the level being brought up to a specified distance from the bottom of the hole. The coolant is refilled at the reservoir that is located on the inverter assembly and must be bled properly before placing the vehicle back into service. Always use the recommended fluids and procedures when servicing any vehicle.

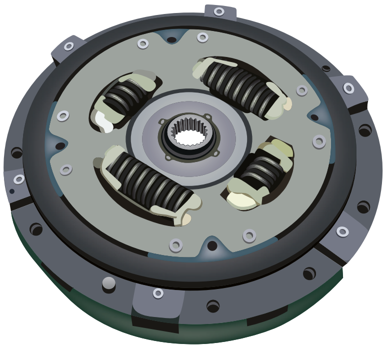

FIGURE 131–31 The flywheel and clutch assembly serve as the dampener between the engine and transmission.

NOTE: The fastest and most reliable way to refill the inverter cooling system is to use an airlift fluid exchange machine. This pulls the cooling system into a vacuum and then injects the coolant into the evacuated system. This method fills the system quickly and eliminates air bubbles.

HYBRID TRANSMISSION DIAGNOSIS

STEPS INVOLVED When diagnosing a hybrid electric vehicle (HEV) transmission concerns, perform the following steps:

STEP 1 The first step is to verify the customer complaint.

STEP 2 Check the fluid level and condition.

STEP 3 Check for stored diagnostic trouble codes (DTCs).

STEP 4 Check for any related technical service bulletins (TSBs).

STEP 5 Check scan tool data including checking the adaptive values.

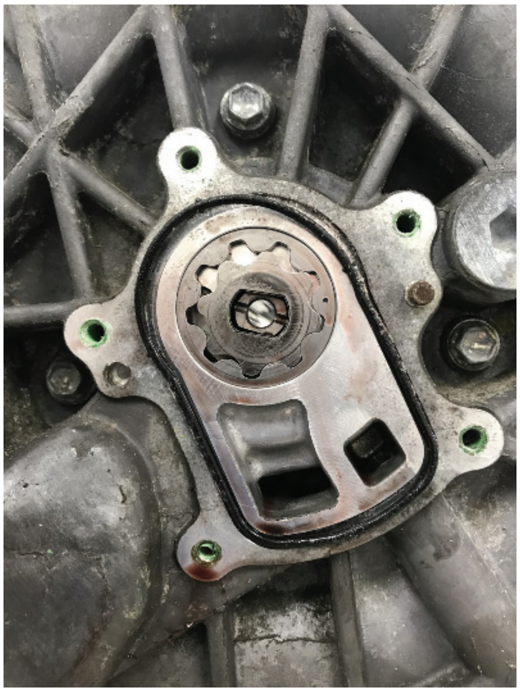

FIGURE 131–32 With the cover removed, the transmission oil pump is visible on the rear of the transmission.

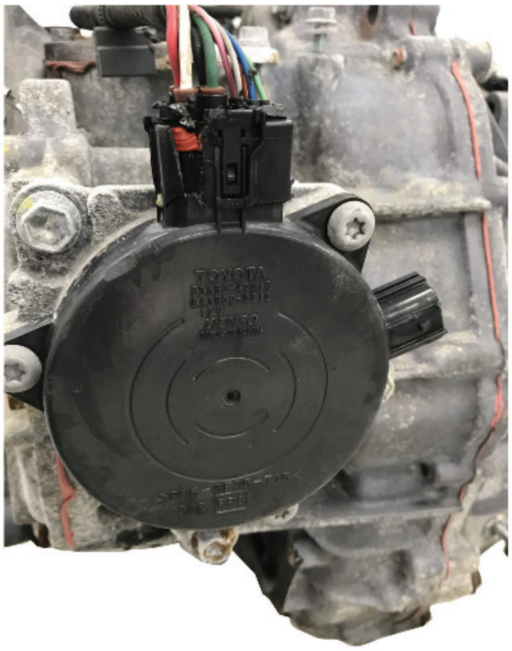

FIGURE 131–33 The electronic actuated park lock mechanism is mounted externally beginning with the 2004 model year.

STEP 6 Perform visual inspections, including checking for recent accident damage, previous repairs, or other issues.

STEP 7 Perform bidirectional control of the transmission using a factory or an enhanced aftermarket scan tool to check operation. This helps to establish if the issue is inside or outside of the transmission/transaxle.

STEP 8 Locate and correct the root cause of the problem.

Always follow the specified diagnostic and repair procedures for the vehicle being serviced.

ELECTRIC VEHICLE TRANSMISSIONS

ACCELERATION VS TOP SPEED Most production electric vehicles use a single-speed transmission. ICEs need many gears because they have a narrow RPM window within which they can operate efficiently. For electric motors, that window is much wider, so a single-speed works for both low-end acceleration and highway driving. It does require some compromise, and so EV manufactures usually design their system for optimum low-end acceleration instead of top speeds. Most electric vehicles have a top speed of 110–125 MPH (180–200 km/h). At top speed the electric motor RPM is 10000 and 18000 RPM, depending on the make and model.

SINGLE-SPEED GEARING The objective of the motor and drivetrain is improving the conversion rate of battery power to actual wheel power. Every one percentage point in energy conversion efficiency translates into 2% more range. Most all-electric vehicles are equipped with just a single speed transmission/transaxle, yet are capable of delivering outstanding performance and acceptable range with motor torque of up to 230 lb-ft (315 Nm) and peak power of 188 HP (140 kW).

FORD MUSTANG MACH-E BorgWarner is producing an Integrated Drive Module (iDM) being used in the Ford Mustang Mach-E. The iDM consists within one compact assembly including the following components:

- Electric traction motor
- Single-speed gearbox
- Thermal-management system (liquid cooling)
- Motor and power electronics

The iDM uses parallel axis gearing, instead featuring a concentric design with outputs on the same axis as the electric motor, resulting in a more compact package.

CHEVROLET BOLT The Chevrolet Bolt drive unit consists of an electric motor and final drive assembly. ● **SEE FIGURE 131–34**.

NISSAN LEAF At the heart of LEAF's powertrain is its three-phase AC electric motor. It produces 40 kilowatts of power and can produce maximum torque within 0.1 seconds. This motor has a permanent magnet rotor core with high-density stator winding. It produces 206.5 pound-feet of torque and weighs 129 pounds. ● **SEE FIGURE 131–38**.

A resolver is incorporated to input rotor position and speed to the Vehicle Control Module (VCM). Resolver calibration data to correct for variations in manufacturing is encoded on the traction motor housing. ● **SEE FIGURE 131–39**.

Instead of a conventional transmission, the LEAF incorporates a reducer that transfers the torque from the traction motor to the drive wheels. The reducer directs the motor's output to provide ideal torque at both low- and high-motor speeds. Compact and lightweight, the reducer minimizes energy loss due to friction. The LEAF's reducer is connected to the electric drive motor. Its components include the input gear, main gear, main shaft, final gear, differential, and parking unit. ● **SEE FIGURE 131–40**.

repairing the reducer. According to the periodic maintenance schedule, the oil level in the reducer must be inspected. If the fluid level is found to be low, it should be filled to the desired level with Nissan genuine Matic Fluid S. The reducer holds approximately 1.1 liter of lubricant.

FREQUENTLY ASKED QUESTION

What Happens When You Shift to Neutral?

When neutral is selected, does it just disconnect the power connections? Or is the motor free to spin? In neutral, there is no power being supplied to the electric traction motor. The motor is never disconnected.

REVIEW QUESTIONS

1. What are the differences in FWD, RWD, and AWD powertrain configurations?
2. Explain how the transmission delivers torque and optimizes fuel economy.
3. Explain how the Toyota power-split system delivers power to the drive wheels.

5. Describe the operation of a single-speed transmission in a typical electric vehicle.

CHAPTER QUIZ

1. In a GM two-mode hybrid electric vehicle, when can the vehicle be powered by electric mode alone?
   a. During the first mode
   b. During the second mode
   c. During either the first or second mode
   d. During heavy load conditions regardless of mode
2. Modifications to automatic transmissions used in hybrid vehicles include ____________.
   a. electric auxiliary transmission fluid pumps
   b. modified torque converter lockup schedule
   c. hydraulic impulse storage accumulator
   d. All of the answers are correct

3. In a Toyota/Lexus hybrid electric vehicle, how is reverse achieved?
    - **a.** The ICE reverses direction and powers the drive wheels
    - **b.** MG2 is used to power the vehicle in reverse
    - **c.** MG1 is used to power the vehicle in reverse
    - **d.** Either b or c depending on model and year
4. A FWD hybrid electric vehicle with an electric rear axle ______________.
    - **a.** has all-wheel drive capabilities
    - **b.** uses a special inverter
    - **c.** has a separate resolver and temperature sensor for the rear axle unit
    - **d.** All of the answers are correct
5. The final drive assembly in an electric vehicle transmission assembly ______________.
    - **a.** transfers torque from the electric motor to the drive wheels
    - **b.** reduces motor speed to produce ideal torque at low and high speeds
    - **c.** provides for a parking mechanism for the assembly
    - **d.** All of the answers are correct
6. What is the first step when diagnosing a hybrid vehicle transmission?
    - **a.** Check the fluid level
    - **b.** Verify the customer concern
    - **c.** Check for trouble codes
    - **d.** Check for Technical Service Bulletins (TSBs)
7. In a Toyota/Lexus hybrid electric vehicle, what is the purpose of MG1?
    - **a.** Start the ICE
    - **b.** Charge the HV battery
    - **c.** Provide additional power to MG2
    - **d.** Both answers a and b are correct
8. The oil pump in the Toyota/Lexus power-split hybrid system ______________.
    - **a.** only turns when the ICE is operating
    - **b.** is located in the rear cover of the transmission behind MG2
    - **c.** only turns when MG2 is operating
    - **d.** Both answers a and b are correct
9. The electric motor in the Ford/Lincoln 10R80 MHT transmission provides ______________.
    - **a.** stop-start capabilities
    - **b.** extra power
    - **c.** extra low-speed torque
    - **d.** All of the answers are correct
10. How many forward speeds does the typical electric vehicle transmission have?
    - **a.** One

AUTOMATIC TRANSMISSION/ TRANSAXLE DIAGNOSIS AND IN-VEHICLE SERVICE

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Explain the process of diagnosing transmission problems.
- Describe how to diagnose transmission fluid leaks.
- Discuss the procedures for performing in-vehicle service.

KEY TERMS:

Diagnostic trouble codes (DTCs) 1682 • Technical service bulletins (TSBs) 1683

TRANSMISSION PROBLEM DIAGNOSIS

VERIFY THE CUSTOMER CONCERN The first step is to verify the customer concern. The customer should be asked the following questions in an effort to determine as much about the problem as possible:

- What exactly seems to be the concern? (Ask the customer to be as detailed as possible.)
- When did the problem first appear?
- Under what conditions do the symptoms occur? (Do they occur first thing in the morning? After the vehicle has been driven for a while?)
- Describe under what driving conditions the problem is noticed, such as when accelerating or while coasting to a stop or some other condition.
- Has the vehicle been serviced recently, such as a fluid change?

FLUID CHECK The first step in diagnosing any problem is to test drive the vehicle and verify the customer complaint (concern). Before test driving the vehicle, check the level and condition of the automatic transmission/transaxle fluid. Follow the procedure for checking the level as published in the owner's manual or factory information. ● **SEE FIGURE 132–1**.

CHECKING FLUID LEVEL WITH A DIPSTICK To check transmission fluid with a dipstick, check the procedure stamped on the dipstick. The usual procedure includes the following steps:

STEP 1 Park the vehicle on a level surface, apply the parking brake securely, and place the gear selector in park or neutral as recommended by the manufacturer. Start the engine and let the temperature of the transmission come up to operating temperature.

STEP 2 Apply the service brakes firmly and move the gear selector to each of the operating ranges. Leave the selector in each position long enough for each gear to become completely engaged.

STEP 3 Return the selector lever to park or neutral, depending on the transmission. Leave the engine running at idle speed.

STEP 4 Clean any dirt from the dipstick cap and remove the dipstick.

STEP 5 Wipe the dipstick clean and return it to the filler pipe, making sure that it is fully seated.

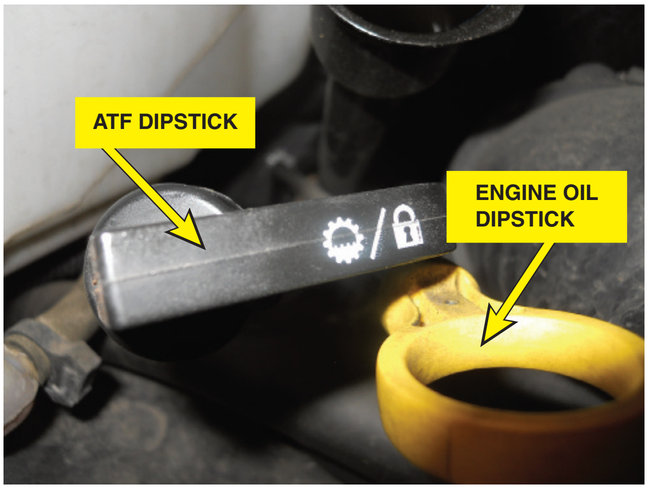

FIGURE 132–1 A typical automatic transmission dipstick (fluid level indicator). Many use a clip to keep it from being forced upward due to pressure changes inside the automatic transmission. A firm seal also helps keep water from getting into the fluid, which can cause severe damage to the clutches and bands.

FIGURE 132–2 The "add" mark on most automatic transmission dipsticks indicates the level is down 0.5 quart (0.5 liter). Always follow the instructions stamped or printed on the dipstick.

STEP 6 Pull the dipstick out again and read the fluid level. ● **SEE FIGURE 132–2**.

Carefully grip the end of the dipstick between two fingers to get an indication of the fluid temperature.

- **a.** If it feels cold, use the COLD marks.
- **b.** If it feels warm, the correct fluid level will be between the HOT and COLD marks.
- **c.** If it is too hot to hold onto, use the HOT marks.

STEP 7 Replace the dipstick completely into the filler tube.

CHECKING FLUID LEVEL WITHOUT A DIPSTICK Some units do not use dipsticks. Fluid level is checked by following the procedure stated in the service information. When checking sealed units, a general procedure is to bring the transmission to operating temperature, and then remove the fluid level plug. Fluid will trickle or weep out of the plug if the level is correct.

- If it runs out, the level is high.
- If there is no fluid, the level is low.

Some manufacturers require a special procedure or tool in order to check the fluid level of their sealed transmissions, so it is wise to review their fluid-checking procedures. A general procedure follows.

To check transmission fluid level on a vehicle without a dipstick, perform the following steps:

STEP 1 Check service information for the correct checking procedure.

STEP 2 Check the transmission temperature using a scan tool. This is very important and the vehicle will usually need to be driven for several miles before the specified fluid temperature is achieved. ● **SEE FIGURE 132–3**.

TECH TIP

Quick-and-Easy Automatic Transmission/Transaxle Diagnosis

An experienced technician told the beginning technician that automatic transmission/transaxle diagnosis is often very easy. For example:

- **If the vehicle does not move in drive or reverse,** remove the transmission/transaxle for service because the problem is likely mechanical rather than hydraulic (valve body) or electrical (computer, solenoids, or sensors). If the unit will not power the vehicle, the unit will more than likely require removal for a thorough mechanical inspection and repair.
- **If the vehicle moves, but does not shift correctly,** the problem is likely electrical (computer, solenoid, or sensor) or hydraulic (valve body) rather than mechanical. This is usually true because if the vehicle is able to move forward and backward, the major mechanical components, though not in like-new condition, are at least able to function. Therefore, correcting the nonmechanical problem should be the technician's first consideration.

STEP 3 Locate and carefully remove the fluid level plug. Note that the level plug can be small, like a pressure check plug, or large, like a conventional plug. The plug can be located in the transmission case or on the bottom or side of the pan.

STEP 4 If fluid drips or seeps from the hole, the level is correct. Add additional fluid of the correct type until the level is correct. If necessary, add additional fluid by pumping it into the fill port located at the side of the case or up through the fluid level checking plug opening.

TEST DRIVE When test driving the vehicle, try to drive the vehicle under the same conditions that the owner noticed the problem.

To ensure a thorough diagnosis, the vehicle should be driven under a variety of conditions to see if it functions correctly, including the following:

1. **From a stop, and accelerated slowly until at highway speed.** This will check if all shifts are occurring and at the correct speeds.
2. **Note how the shifts feel.** The shifts may be too harsh or too soft. This could indicate a fluid pressure problem, or a worn clutch, bands, or accumulator.
3. **Note when the shifts occur.** The shifts may occur too early or too late.
4. **Use all gear selections.** Often a different element of clutch is used for manual gears compared to the same gear when the gear selector is in drive (D). Note any differences that may help in identifying the source of the problem.

COMMANDING SHIFTS Many automatic transmission test tools or scan tools can be used to actually cause the automatic transmission/transaxle to shift electrically. The tester is connected to the electrical connector at the automatic transmission/transaxle after disconnecting the factory connector. To perform this simple test, perform the following steps:

STEP 1 Safely hoist the vehicle.

STEP 2 Start the engine.

STEP 3 Place the gear selector in the drive position and use the tester or scan tool to command the various shift solenoids to actuate.

Results: If the shift occurs when commanded, the hydraulic system is functioning. If the tester commands a shift to occur and a shift does not occur, the service technician knows that the problem is either in the solenoid itself or the hydraulic system that actuates the clutch or band to accomplish the shift. ● **SEE FIGURE 132–4**.

CAUTION: A scan tool or special tester can be used to command shift while an assistant is driving the vehicle instead of on a hoist as stated above. If commanding a shift when driving, use extreme care as some shift may be harsh and damage to the vehicle could occur if the commanded shift occurs at too high a vehicle speed.

CHECK DIAGNOSTIC TROUBLE CODES If there are any **diagnostic trouble codes (DTCs)** stored in the memory of the vehicle computer, then a problem has been detected that should be corrected before further testing. ● **SEE CHART 132–1** for transmission-related diagnostic trouble codes.

A weak or missing engine cylinder can cause the vehicle to lack power, jerk, and hesitate. These symptoms are often blamed on an incorrectly shifting or slipping automatic transmission/transaxle. If a P0300 diagnostic code (random engine misfire code) is set, repair the cause of the misfire before trying to diagnose the transmission.

SCAN DATA A scan tool can display information about the various sensors and components that can assist the service technician in determining the cause of many automatic transmission/transaxle problems.

A properly operating engine should display the following readings with the engine at idle and operating in closed loop.

- **Engine coolant temperature (ECT)**—between 180 and 215°F (82 and 102°C)
- **Throttle position (TP) sensor**—usually between 0.5 and 4.5 volts and varying directly with throttle movement
- **Accelerator pedal position sensor (APPS)** —usually two or more sensors on differing scales (0.4 to 4.6 volts) and varying with accelerator pedal movement
- **Fuel injector pulse width**—1.5 to 3.5 ms
- **Upstream oxygen sensor (O2S)**—voltage varying between 200 and 800 mV
- **Air–fuel ratio sensor(s) (if equipped)**—scan tool to read fairly low and steady
- **Transmission fluid temperature**—less than 275°F (135°C)
- **Brake switch—**scan data to show a change when brake pedal is pressed and released
- **Manifold absolute pressure (MAP) sensor**—with the engine idling in park or neutral, the voltage should be within 0.88 and 1.62 volts or between 102 and 109 Hz for a Ford MAP sensor
- **Mass airflow sensor (MAF)**—warm engine in park with no load typically reads grams per second within 20% of the engine's liters of displacement, a 3.5 liter engine will show fairly close to 3.5 g/s of airflow at idle
- **Vehicle speed (VS) sensor**—source can vary: derived from ABS wheel speed sensors, output speed sensor of transmission, or a dedicated sensor on transmission or transfer case
- **Idle speed**—check for normal idle speed; vehicles with electronic throttle control are usually 2% to 3% open at warm idle in park and vehicles with IAC (idle air control) valves are typically 10 to 30 steps if stepper motor type or 250 to 400 milliamps if linear
- **Shift solenoids**—check for the proper voltage and current of the shift solenoids using a factory or factory-level scan tool

Observe the operation of the command for the shift solenoids and the TCC solenoid while driving the vehicle. This information confirms that the computer is commanding the

operation; it does not mean that the solenoids are working correctly. Therefore, if the scan data indicates that a particular solenoid is being commanded on and nothing occurs, then the problem could be caused by a defect with the following:

1. Hydraulic component (clutch, band, etc.)
2. Solenoid
3. Fault in the wiring to the solenoid or from the solenoid to the PCM or TCM

● **SEE FIGURE 132–5.**

Use a scan tool to check the engine operation values and inputs that could affect transmission operation. ● **SEE CHART 132–2.**

CHECK TECHNICAL SERVICE BULLETINS According to studies performed by automobile manufacturers, as many as 30% of the vehicles can be repaired following the information, suggestions, or instructions concerning replacement parts found in a **technical service bulletin (TSB)**. Before an accurate search of a TSB can be performed, the technician must know the following information about the vehicle under service:

- Make, model, and year of the vehicle
- Engine size and VIN
- Transmission type
- Federal, high-altitude, or California emissions
- Build date (sometimes)

Diagnostic trouble codes must be known before searching for TSBs because bulletins often include information on solving problems that involve a stored code.

TRANSMISSION/TRANSAXLE IDENTIFICATION The identification of the transmission/transaxle can sometimes be a challenge.

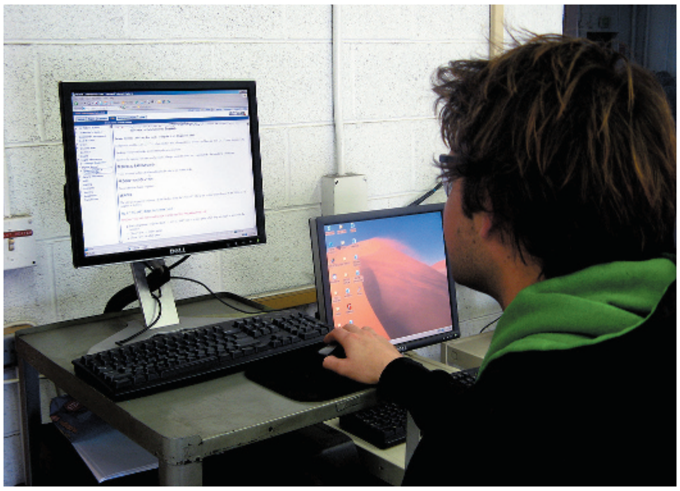

FIGURE 132–6 Checking service information for how to perform diagnosis on an automatic transmission fault is a wise step.

TECH TIP

You'd Ask a Friend, Wouldn't You?

If you were stuck on a difficult transmission problem, you would probably ask a technician friend for ideas. Think of the service information as a friend with some inside information. It is written by the people who know how the system works in detail.

Such advice is available in service information. If the technician follows the recommended steps, chances are excellent of finding the problem—just like getting the advice of an experienced technician. ● **SEE FIGURE 132–6**.

CASE STUDY

The Stalling Impala

The owner of a Chevrolet Impala complained that the vehicle would occasionally stall when slowing to a stop. The problem only occurred after at least 20 miles and occurred more frequently in warm weather. The owner also indicated even though this vehicle was equipped with an automatic transmission it felt like the clutch not being depressed on a manual transmission. Thankfully, the service technician was aware of this common problem and installed a new torque converter clutch solenoid.

When the original solenoid got hot, it became stuck in the applied position. Even though the voltage was removed from the solenoid when the brakes were applied, the solenoid and the torque converter clutch (TCC) remained applied. ● **SEE FIGURE 132–7**.

Summary:

Complaint—The owner of the vehicle complained that the engine would stall when slowing to a stop, but only after the car was driven for 20 miles or further.
Cause—A defective torque converter clutch (TCC) solenoid.
Correction—Replacing the TCC solenoid cured the engine staling problem.

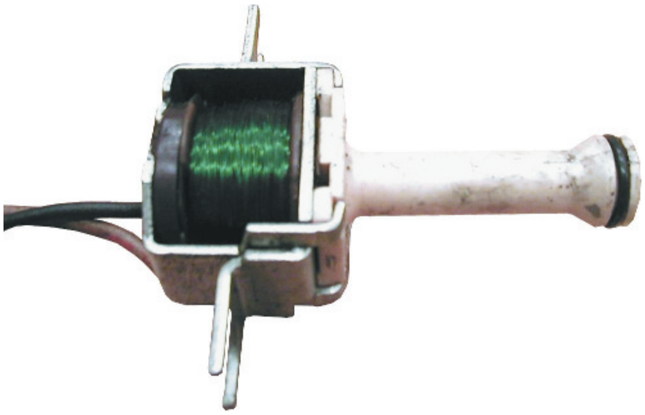

FIGURE 132–7 A torque converter clutch (TCC) solenoid. This TCC can be replaced on a General Motors vehicle without having to remove the transmission/transaxle from the vehicle.

Check service information to determine the identification of the unit based on one or more of the following:

- Vehicle identification number
- Engine (transmissions can vary internally based on engine size)
- Regular production option (RPO) code
- Transmission/transaxle identification plate information
- Pan shape and/or number of bolts used on the pan

STALL TESTING THE TORQUE CONVERTER

A stall test is often performed to verify the proper operation of the torque converter.

CAUTION: Some vehicle manufacturers do not recommend performing a stall test because it can be dangerous if the brakes were to fail during the test and it places stress on the engine. Always follow the manufacturer's recommended service procedures.

Performing a stall test includes the following steps:

STEP 1 Drive the vehicle until normal operating temperature is achieved.

STEP 2 Check the stall speed specifications for the vehicle being serviced and connect a tachometer to the engine.

STEP 3 With your left foot firmly applied to the brake pedal, move the shift selector in the drive position and depress the accelerator pedal to the floor. Observe the maximum engine speed. This engine speed is the stall speed. ● **SEE FIGURE 132–8.**

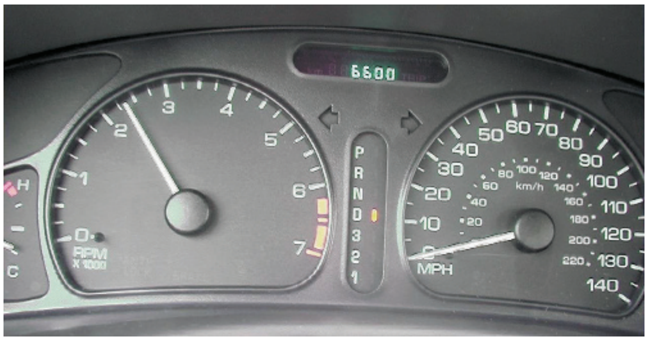

FIGURE 132–8 This 4-cylinder General Motors vehicle has a stall speed of about 2350 RPM. Notice that the gear selector is in drive and the speedometer is reading zero.

TECH TIP

Using the Wrong ATF Could Cause Shifting Problems

If the incorrect automatic transmission fluid has been used, such as during a previous repair, the following problems could occur:

- Hard shifts
- Slipping
- Shudder (feels like a vibration similar to driving over a rippled road surface)

If any of these conditions are present, check with the customer to find out if the transmission had been recently serviced or if the customer added new fluid or some additive. Often, some of the above concerns can be solved by replacing fluid with the specified fluid.

STEP 4 Release the accelerator as soon as possible to avoid the possibility of overheating the automatic transmission fluid. Repeat the test with the gear selector in reverse.

NOTE: Checking the stall speed in reverse is just a double check. This is done because the line pressure is higher in reverse and, as a result, the higher pressure will hold clutches better and keep them from slipping. A slipping forward clutch could cause the engine speed to be higher than normal and would affect the recorded stall speed.

STEP 5 Compare results with the specifications:

- *If the engine speed is higher than specifications,* then a holding clutch or band is slipping.
- *If the engine speed is lower than specifications,* then the torque converter is defective (one-way clutch or stator is slipping) or the engine is not producing normal power output.

Both conditions can result in reduced vehicle performance and slow acceleration.

NOTE: There are many other possible causes of poor performance or sluggish acceleration besides a fault with the automatic transmission/transaxle. The stall test is just one test that can be performed to help narrow the problem to the root cause.

TRANSMISSION FLUID LEAK DIAGNOSIS

VISUAL INSPECTION

To locate a leak from an automatic transmission/transaxle, the first step is to perform a thorough visual inspection. Start by checking the fluid level:

- If too high, then the fluid loss could be caused by it being overfilled and forced out of the vent opening located at the top of the unit.
- If too low, a fluid leak is the most likely cause and should be corrected as soon as possible to prevent damage, wear, or harm to the transmission/transaxle parts due to low fluid level.

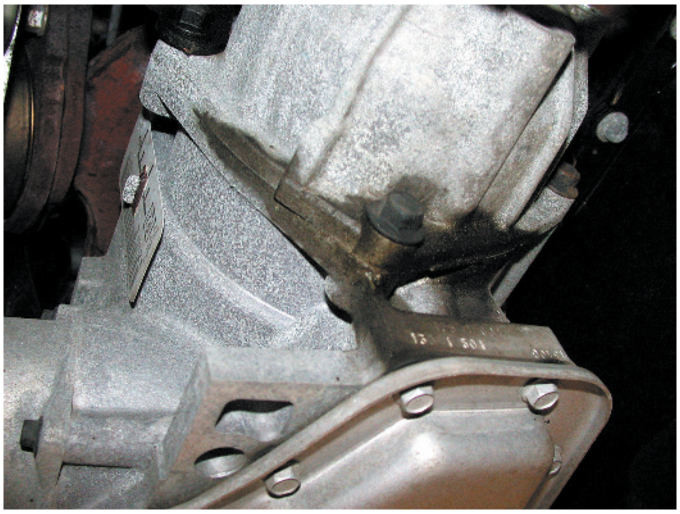

FIGURE 132–9 Sometimes the location of a transmission fluid leak is easy to see, but with others it can be difficult to find the exact location. Look closely at places where O-rings or gaskets are used, as these are the most common areas where fluid leaks occur.

Perform a visual inspection using the following steps:

STEP 1 Use a trouble light and start the visual inspection under the hood and look for signs of fluid leakage on the top of the unit. Because fluids flow downward due to gravity, the fluid will be most likely seen from underneath the vehicle; however, the source could be at or the near the top.

STEP 2 Hoist the vehicle safely and look for the highest and most forward place where fluid is seen. Due to gravity and the forward movement of the vehicle, leaking fluid will travel downward and toward the rear. ● **SEE FIGURE 132–9**.

DYE TESTING Often the exact location of a fluid leak is difficult to locate. Using a dye designed for ATF and a black light is an effective method to locate ATF leaks. To check for leaks using a dye, perform the following steps:

STEP 1 Add a small bottle of dye that is designed for use in ATF into the dipstick tube using a transmission funnel.

CAUTION: Do not use dye designed for use in coolant or air-conditioning systems or severe harm can occur to the automatic transmission/transaxle.

STEP 2 Drive the vehicle until the fluid has reached normal operating temperature.

STEP 3 Safely hoist the vehicle.

STEP 4 Using a black light, look for the highest and most forward place where a greenish stain appears. This is the source of the leak. ● **SEE FIGURE 132–10**.

TORQUE CONVERTER CLUTCH DIAGNOSIS The torque converter clutch is usually applied above 30 MPH (48 km/h) when the automatic transmission/transaxle is in second, third, or overdrive gear, depending on the vehicle speed and the throttle position. It is often difficult to distinguish between a normal shift and the application of the torque converter clutch. The torque converter clutch (TCC) may not even be applying due to a fault in the computer sensors, wiring, or the TCC solenoid.

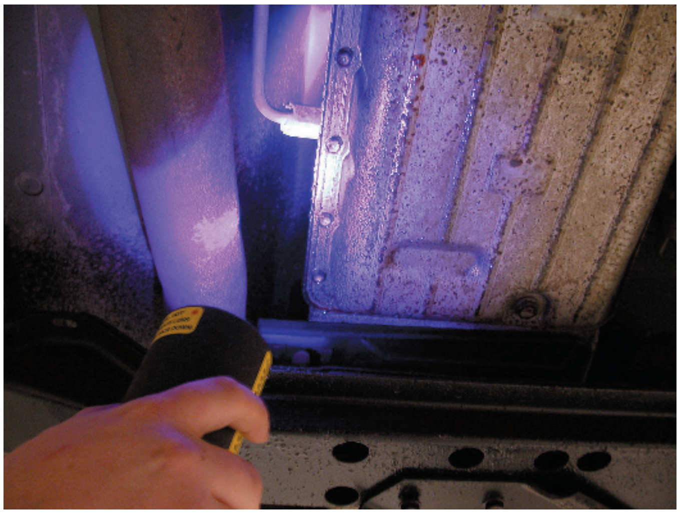

FIGURE 132–10 A black light being used to locate the source of an automatic transmission fluid leak.

NOTE: If the torque converter clutch does not apply, a drop in fuel economy of 3 to 4 miles per gallon is commonly reported. If the TCC fails to apply on an automatic transmission/transaxle, the automatic transmission fluid is likely to become overheated due to the torque converter slip. The higher fluid temperature can cause the automatic transmission/transaxle to fail.

TECH TIP

Vibration—Engine or Transmission?

A vibration is often difficult to diagnose. One method is to separate (unbolt) the torque converter from the engine drive flex plate. Push the torque converter as far toward the transmission/transaxle as possible, then start the engine. If the vibration is gone, the problem is due to a fault in the torque converter, pump assembly, or other component that is constantly rotating with the engine running. If the vibration is still present, then the cause is due to an engine or accessory problem.

TECH TIP

Look at the Command and the Engine Speed

Using a scan tool is very helpful when diagnosing automatic transmission problems. However, the display often shows when the shift has been commanded and may not show if the shift or the TCC engagement actually occurred. To help ensure that the shifts have in fact occurred, also watch the engine speed. Many factory or enhanced scan tools can also display the engagement speed. A slow engagement is usually caused by worn clutches. Check service information for the exact parameters and range of proper operation for the vehicle being diagnosed.

To test for proper operation of the torque converter clutch, simply drive the vehicle and watch either the tachometer on the dash or connect a scan tool to observe the engine RPM:

STEP 1 Drive the vehicle until the engine has reached normal operating temperature.

STEP 2 Drive the vehicle on a flat, level road away from any traffic about 50 MPH (80 km/h).

STEP 3 While maintaining constant speed with your right foot on the accelerator, gently apply the brake pedal with your left foot to open the electrical circuit for the torque converter clutch through the brake switch. The TCC will disengage and the RPM should increase about 150 to 250 RPM and then drop back when the brake pedal is released. This RPM change is evidence that the TCC is, in fact, working. If the torque converter clutch is not operating, consult the factory information for the exact procedures to follow.

NOTE: If the temperature of the automatic transmission fluid (ATF) is too high, the computer will modify the shift pattern (usually disabling overdrive) and engage the TCC at slower speeds in an attempt to drop the temperature of the ATF to less harmful temperatures. Also if the temperature is too low, the PCM may not allow lockup and may limit the number of forward gears available until the transmission fluid warms up. This computer control of the shifting may be noticeable to the driver as a fault.

RANGE CHARTS All vehicle manufacturers publish range charts that indicate which holding device is used for each gear selection. Knowing which component is being used for each gear helps the service technician determine the cause of a failure or problem. **SEE CHART 132–3**.

PRESSURE TESTING Pressure testing involves connecting a pressure gauge to pressure taps located on the outside of the automatic transmission/transaxle. ● **SEE FIGURE 132–11**.

CASE STUDY

The Customized Van Story

The owner of a customized General Motors van equipped with an electronically controlled automatic transmission (4L80-E) complained that the automatic transmission downshifted into second gear and stayed in second gear whenever the headlights were turned on. The transmission shifted okay when the headlights were turned off. After hours of troubleshooting, including the replacement of the vehicle computer (which did not help), the technician discovered that 4 volts DC were on the one wire leading from the vehicle speed (VS) sensor to the vehicle computer whenever the headlights were turned on. Obviously, there was a short to voltage between a light wire and the sensor wire. Instead of totally disassembling the van, the technician decided to replace the wire with a new one, and the problem was solved. The 4 volts DC apparently shut down the computer. With both solenoids A and B off, the transmission was in second gear. This is the default gear or the limp-in-mode gear for this transmission. After replacing the wire, the automatic transmission returned to normal operation:

Summary:

Complaint—The customer stated that whenever the headlights we on, the transmission would not shift. The transmission worked fine if the headlights were turned off.

Cause—A wiring fault caused a four-volt DC current to be applied to the vehicle speed sensor wiring.

Correction—A new wire was run and this corrected the default gear from being used when the headlights were on.

CHART 132–4

A pressure chart for the Ford 6F50N/GM 6T70 transaxle.

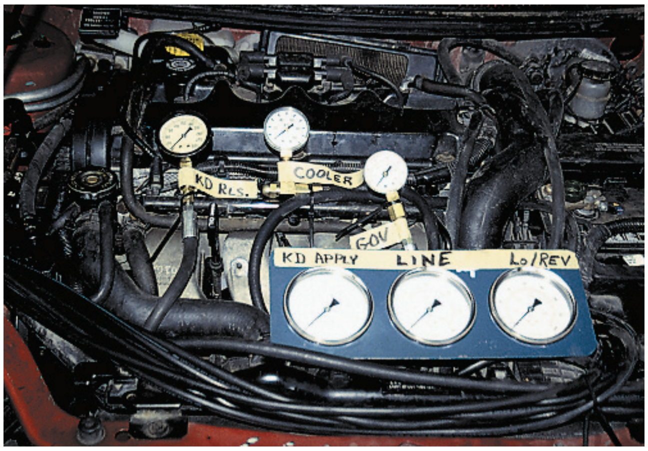

FIGURE 132–12 Six pressure gauges are installed on this vehicle to show students how the pressures vary and how the gauges can be used to find faults or possible problem areas before the unit is removed and disassembled.

After connecting the pressure gauge(s) to the transmission/transaxle, start the engine and select the gear being monitored. Check service information for the specified pressures.

● **SEE CHART 132–4** for a typical pressure chart.

If the pressure is not within specifications, then the technician knows that the fault is internal and usually involves either removing the valve body, or in many cases, removing the automatic transmission/transaxle from the vehicle. ● **SEE FIGURE 132–12.**

TRANSDUCERS Pressure switches are used to verify that solenoids and/or valves have done their job. They do not read actual pressure as they are usually controlled by a spring rated at a certain number of pounds. A transducer-equipped vehicle will usually provide an actual pressure reading on a scan tool. Many vehicles with variable line pressure will have a transducer.

IN-VEHICLE SERVICE

PAN REMOVAL Check service information for the exact procedure to follow when removing the pan. Some transaxles are equipped with a side pan that either may nor may not be needed to be removed when serving the assembly. The usual procedure includes the following steps:

STEP 1 Hoist the vehicle safely.

STEP 2 Place a large drain pan under the transmission/transaxle pan.

STEP 3 Loosen all of the fasteners except for those at one end. Allow the pan to drop down slightly at one end allowing fluid to drain into the drain pan.

● **SEE FIGURE 132–13.**

STEP 4 After the fluid has stopped flowing from the pan, carefully remove the last retaining bolts, slowly lower the pan, and allow any remaining fluid to flow into the drain pan.

STEP 5 Dispose of or recycle the used automatic transmission fluid according to state or local laws.

STEP 6 Remove all of the oil pan bolts except for two at one end. This will allow the pan to drop and empty most of the ATF into the drain container without falling. After most of the ATF has drained, remove the remaining bolts and remove the pan.

STEP 7 Inspect the inside of the pan for excessive friction material and wear metals (such as lead and copper from bushings). Use a magnet to check for steel particles, which would indicate serious wear to major components. ● **SEE FIGURE 132–14.**

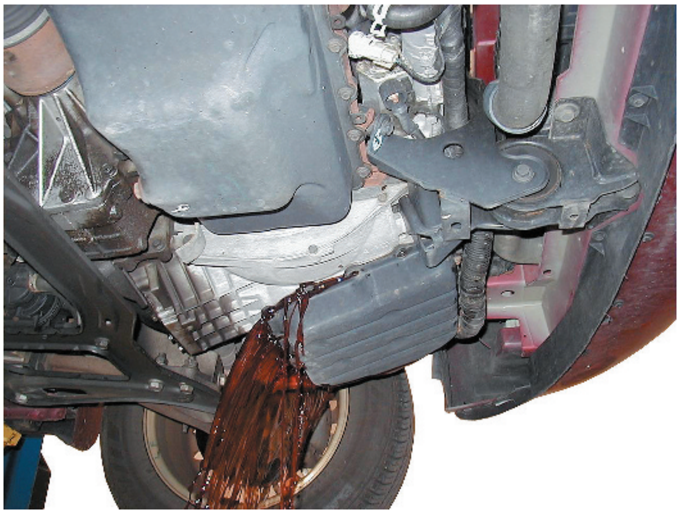

FIGURE 132–13 Draining the fluid from an automatic transaxle by allowing the fluid to flow into a container after most of the retaining bolts have been removed.

FREQUENTLY ASKED QUESTION

What Is Wrong When My Automatic Transmission Does Not Upshift?

The following examples can cause the automatic transmission/transaxle to fail to upshift:

- A *defective governor* (if so equipped) will often not allow any automatic transmission/transaxle to shift out of first gear or stuck in high gear.
- A *defective vacuum modulator* (if so equipped) or misadjusted *throttle valve* will often delay the shift until a very high speed is achieved.
- A *fault in the PCM, TCM, or a speed sensor* on electronically controlled automatic transmissions/transaxles will occur when one gear, usually second or third, is selected and the unit will not shift out of that gear.

WARNING

The automatic transmission fluid may be hot enough to cause personal injury. Wear protective clothing and avoid contact with the hot fluid.

NOTE: The presence of metal particles in the pan of an automatic transmission/transaxle does not necessarily mean that a part(s) has failed or needs to be replaced. Some wear is normal. If there are a lot of metallic particles in the pan, then this may be an indication of severe gear failure that may require replacement. Use a magnet to check for steel particles. Ask the advice of an experienced transmission expert, if in doubt, about whether the wear should be considered "normal."

FILTER REPLACEMENT Check service information for the exact procedure to follow when replacing the filter. Most are retained by a clip or a bolt. ● **SEE FIGURE 132–15**.

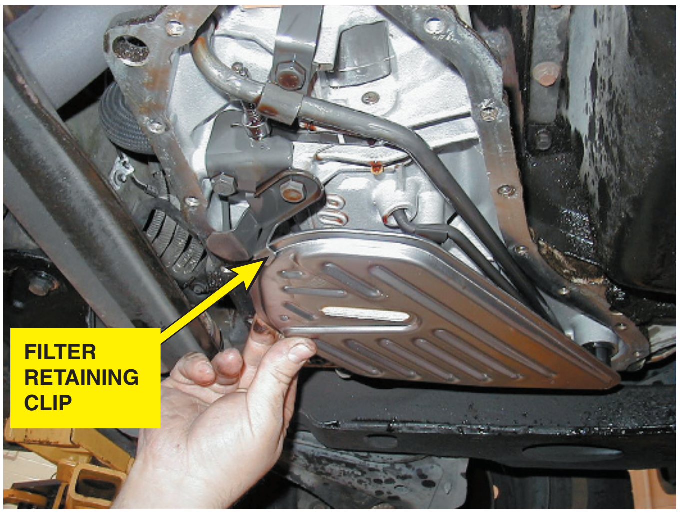

FIGURE 132–15 Always check that the filter is secured by a clip or other fastener to keep it from dropping out of location.

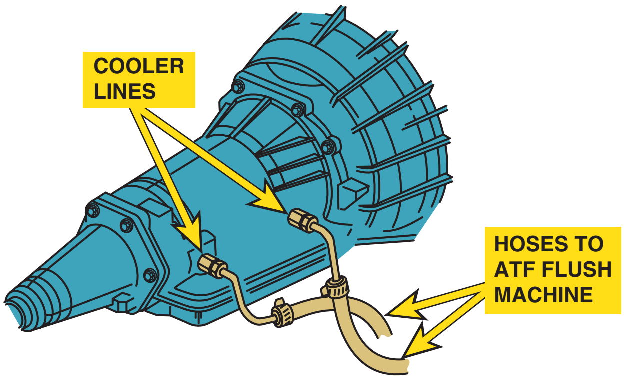

FIGURE 132–16 A fluid exchange machine uses the engine and the transmission pump to force the fluid into the machine where the old fluid is used to push against a diaphragm, which then forces new fluid back through the transmission. A sight glass is used to show the technician the fluid, so the process can be stopped when only clean, new fluid is seen flowing through the cooler line.

CAUTION: Extra or missing O-rings on filter necks and/or cracked or mispositioned filter filler necks cause many problems. The pump may intermittently ingest air, leading to transmission or driveability complaints such as rough idle or an engine stalling condition.

FLUSHING ATF The following are ways to flush automatic transmission fluid:

1. Connect the cooler lines to a machine that exchanges the old fluid with new fluid. ● **SEE FIGURE 132–16**.
2. Use a machine to draw out the old fluid though the filler tube and then refill it with clean fluid.
3. Use a machine that attaches to the pump inlet after the pan and filter have been removed. The machine uses its own pump to force all of the old fluid from the transmission or transaxle.
4. Drain and refill. Using this method, recommended by Honda and Acura, means that about 3 quarts are being replaced. The vehicle should be driven and the drain and refill formed another two times.

Most experts recommend that the filter be replaced, so the pan should be removed (except for Honda and Acura) and the filter replaced after any of the above methods are used. ● **SEE FIGURE 132–17**.

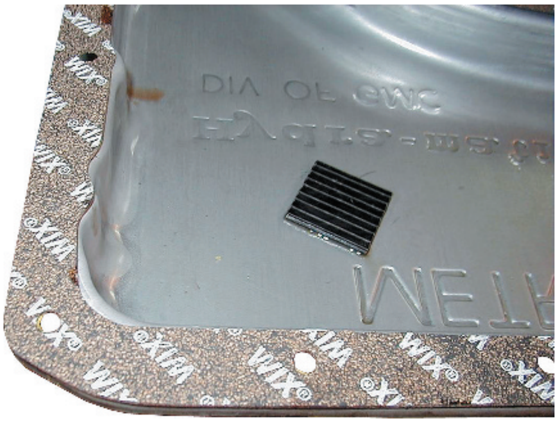

FIGURE 132–17 In this case, the cork-rubber gasket is glued to the pan and is ready to be installed. The retaining bolts need to be tightened in sequence, but be aware that overtightening will cause a leak. Also, some manufacturers recommend using only an RTV sealer, but never use an RTV sealer and a gasket together.

TECH TIP

Use Old Headlights to Check Wiring

The proper operation of any electronically controlled automatic transmission/transaxle depends on having electrical power available to operate the solenoids. Before removing the unit from the vehicle, use a headlight to check if there is enough current being sent to the unit. Unplug the electrical connection that supplies 12 volts, usually from the ignition switch. Use a headlight and attach wires to the ground and the bright filament terminals.

Attach one test lead from a headlight to the terminal that supplies 12 volts to the unit. Attach the other lead from the headlight to a good clean chassis or transmission ground such as the case. Turn ignition key on, engine off (KOEO), and observe the headlight.

- If the headlight is dim, there is a voltage drop between the source (battery) and the transmission feed. Check the wires directly leaving the ignition switch or transmission control relay. If the headlight is still dim, replace the ignition switch or transmission feed relay. ● **SEE FIGURE 132–18**.
- If the headlight is off, then there is an open circuit between the battery and the transmission/transaxle. Follow electrical troubleshooting procedures to find and repair the open circuit.
- If the headlight is bright, there is enough voltage and current being supplied to the transmission/transaxle to correctly operate all of the solenoids. ● **SEE FIGURE 132–19**.

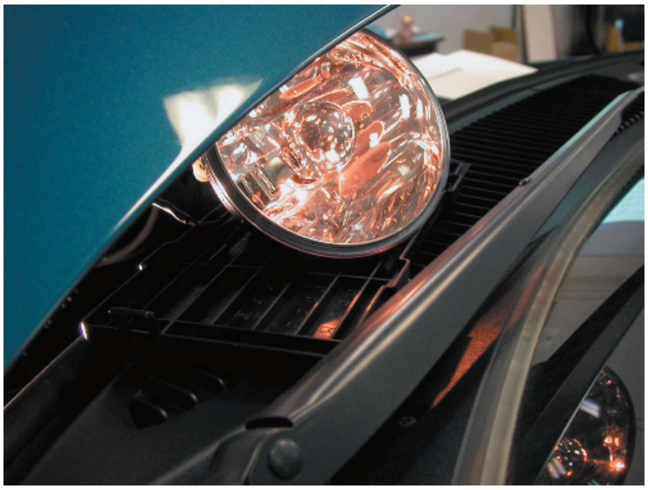

FIGURE 132–18 A dim headlight indicates excessive resistance between the battery and the electrical connector to the automatic transmission/transaxle.

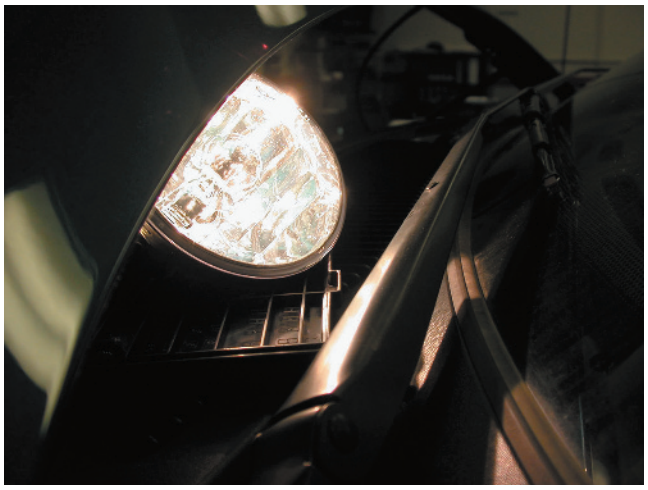

FIGURE 132–19 A bright headlight indicates that there should be sufficient current flow available at the automatic transmission/transaxle to operate all the solenoids correctly.

LINKAGE ADJUSTMENT The linkage between the shift selector and the automatic transmission should be checked for proper adjustment whenever there is a transmission-related problem. The linkage may need to be adjusted to compensate for worn linkage components. Before adjusting the linkage, check the engine and transmission/transaxle mounts carefully because a defective mount is a common reason for needing a linkage adjustment.

REVIEW QUESTIONS

1. What tests can be performed on an automatic transmission/transaxle to determine any faults while the unit is still in the vehicle?
2. How does a defective torque converter clutch solenoid cause the vehicle to stall when the vehicle is slowing to a stop?
3. How is the ATF level determined on a transmission/transaxle that does not have a dipstick?
4. How is a pressure test of the mainline and other pressures of an automatic transmission/transaxle performed?
5. What precautions have to be used when stall testing?

CHAPTER QUIZ

1. Technician A says that the PCM should be checked for any stored diagnostic trouble codes when diagnosing a transmission fault. Technician B says that technical service bulletins (TSBs) should be checked whenever there is a transmission-related customer concern. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
2. A vehicle is being tested using a scan tool. Technician A says that the throttle position (TP) sensor should read between 0 and 1 volt. Technician B says that a factory or factory level scan tool is needed to check for proper voltage and current of the shift solenoids. Which technician is correct?

AUTOMATIC TRANSMISSION/ TRANSAXLE UNIT REPAIR

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Explain how to verify the need for unit repair.
- Discuss the steps involved in removing the automatic transmission/transaxle.
- Discuss the steps involved in disassembling the automatic transmission/transaxle.
- Describe how to reassemble an automatic transmission/transaxle.
- Discuss how to flush the cooler and torque converter.
- Discuss dynamometer testing the automatic transmission/transaxle.
- Describe how to reinstall the automatic transmission/transaxle.
- Describe road testing.

KEY TERMS:

Air pressure check 1698 • Holding fixture 1694 • Tag number 1693

VERIFY THE NEED FOR UNIT REPAIR

VERIFY THE FAULT It is not unusual for a transmission or transaxle to be removed from the vehicle when the fault could have been repaired with the unit still in the vehicle. Or the fault could be due to an electrical or engine-related fault outside the transmission/transaxle. Check with all of the following to be sure that the unit needs to be removed from the vehicle:

- A knowledgeable technician
- Service information
- A hotline service provider, such as Identifix (www.identifix.com)

Use these resources to verify that the fault is inside, not outside, the unit.

IN-VEHICLE REPAIRS Not all mechanical faults require that the automatic transmission/transaxle be removed from the vehicle. Faults that can usually be repaired with the unit still in the vehicle include any valve-body-related concerns.

● **SEE FIGURE 133–1.**

Depending on the transmission/transaxle, it may be possible to disassemble and repair many mechanical components of the unit while it remains in the vehicle. Parts and components that may be replaced with the transmission/transaxle still in the vehicle include

- Pressure switches
- Transmission range switch
- Turbine and output speed sensors
- Extension housing gasket
- Drive axle seals
- Valve body replacement

Check service information for details on what can be replaced with the unit in the vehicle.

IDENTIFY THE UNIT Before removing the transmission/transaxle for replacement or repair, be sure that the unit is properly identified. This identification is critical because of the following:

1. The final drive ratio in transaxles can vary depending on the application; and using the wrong unit can cause shifting and other issues such as gear ratio–related diagnostic trouble codes.
2. The internal gear ratios can vary depending on exact application of the unit.

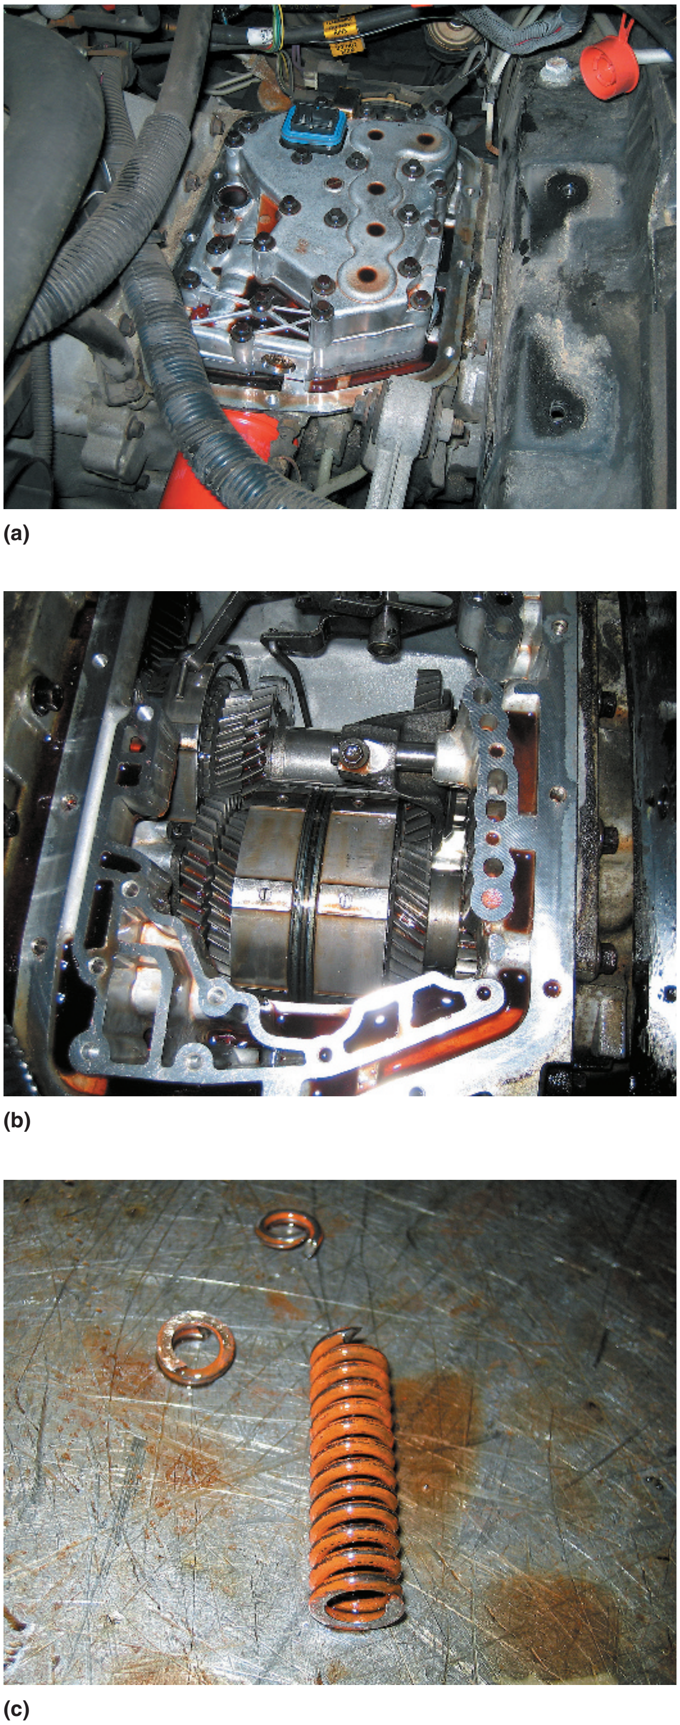

FIGURE 133–1 (a) This Saturn did not shift correctly and one technician was ready to replace the unit; however, another technician thought that the problem could be due to a fault in the valve body. (b) Removing the valve body shows the nonplanetary gears used in the Saturn automatic transaxle. (c) The valve body was disassembled and a broken pressure regulator spring was found to be the cause of the customer concern.

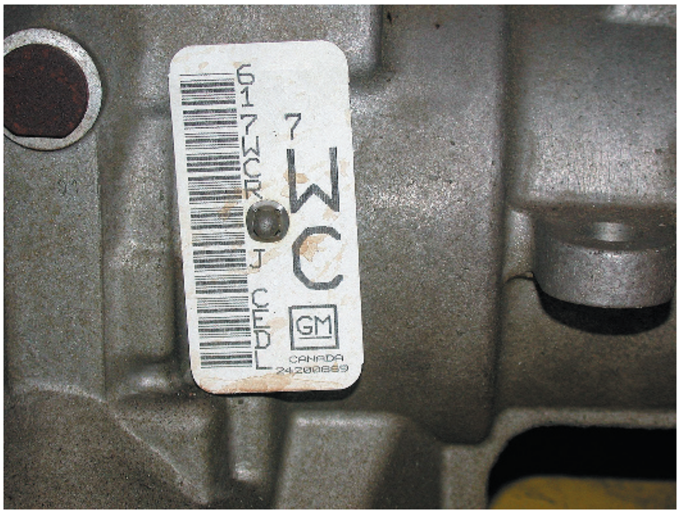

FIGURE 133–2 A transmission identification number on the side of the unit. The information on this tag is needed when ordering parts, as there are often several versions of the same transmission used in similar vehicles and the differences could affect the parts needed.

3. Sometimes the vehicle identification number (VIN) is needed to obtain the correct parts, but more often the transmission/transaxle identification number, also called the **tag number**, is the identification needed to be assured of ordering and receiving the proper parts.

   ● **SEE FIGURE 133–2**.

REMOVING THE AUTOMATIC TRANSMISSION/TRANSAXLE FOR SERVICE

STEPS INVOLVED Removing an automatic transmission/transaxle from a vehicle includes many steps to avoid doing damage to the vehicle or personal harm. Always follow the vehicle manufacturer's recommended procedures. Most procedures include the following steps:

STEP 1 Disconnect the negative (−) battery cable from the battery. This prevents the possibility of an accidental short circuit that could damage the vehicle or cause a spark that could start a fire.

STEP 2 Hoist the vehicle safely and drain the fluid from the unit.

STEP 3 Disconnect the driveshaft or drive axle shafts.

STEP 4 Disconnect all cooler lines, linkage, and electrical connections. Be sure to label each to ensure proper reinstallation. Also be sure to label all electrical connectors so that they can be reinstalled in the proper location.

STEP 5 Disconnect the torque converter from the flex (drive) plate of the engine.

STEP 6 Support the engine before disconnecting the automatic transmission/transaxle. ● **SEE FIGURE 133–3**.

STEP 7 Remove the transmission/transaxle mounting fasteners.

STEP 8 Support the transmission/transaxle on a jack and remove the attaching bolts at the bell housing of the engine. ● **SEE FIGURE 133–4**.

STEP 9 Remove the transmission/transaxle from the vehicle.

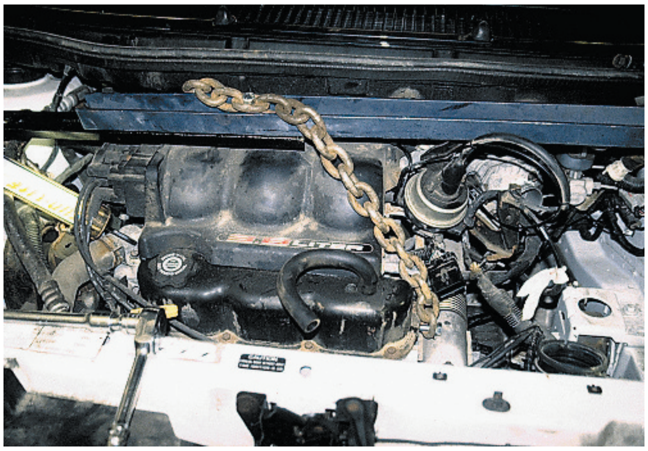

FIGURE 133–3 A chain and holding fixture being used on this front-wheel-drive vehicle to support the engine when the transaxle is removed.

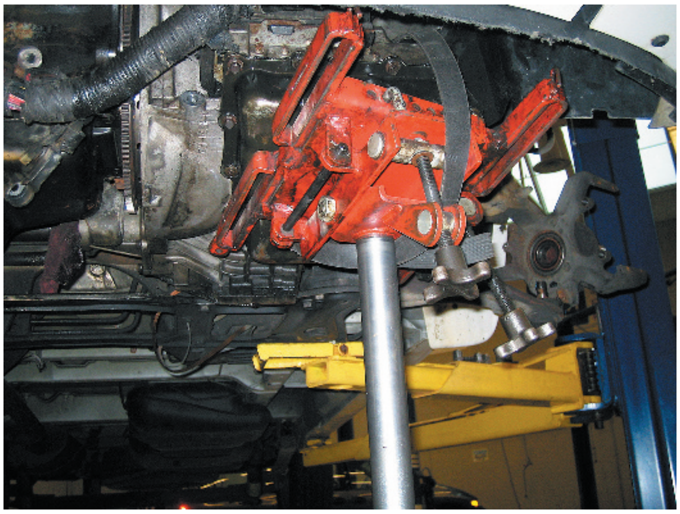

FIGURE 133–4 A transaxle being supported by a transmission jack prior to removal of the unit from underneath the vehicle.

AUTOMATIC TRANSMISSION/ TRANSAXLE DISASSEMBLY

MOUNT TO HOLDING FIXTURE For best results, the automatic transmission/transaxle should be attached to a **holding fixture** that allows the unit to be rotated yet properly supported during disassembly and reassembly. ● **SEE FIGURE 133–5**.

TORQUE CONVERTER CHECKS Remove the torque converter and drain the fluid by tipping it so the fluid runs out into a suitable container. Check the torque converter for the following:

- Visually check for wetness that could indicate a leak such as at the welded seam.
- Check for damage to the pump drive tags.
- Inspect the hub for seal and wear.
- Check that the one-way clutch of the stator is working.
- Check for end play of the stator. ● **SEE FIGURE 133–6**.

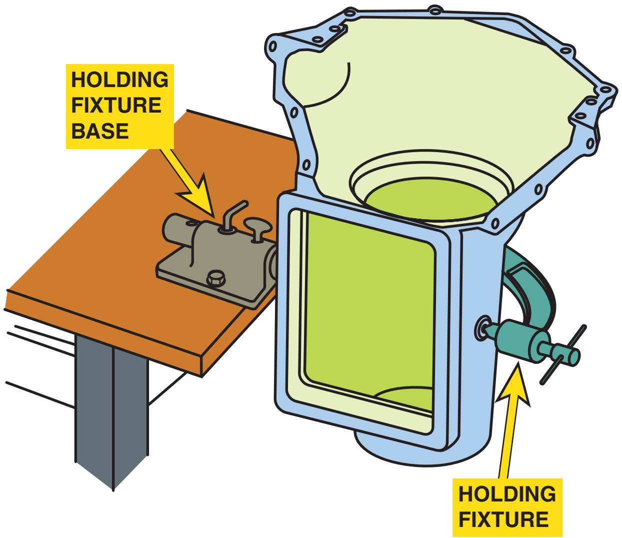

FIGURE 133–5 A holding fixture makes working on a transmission easier.

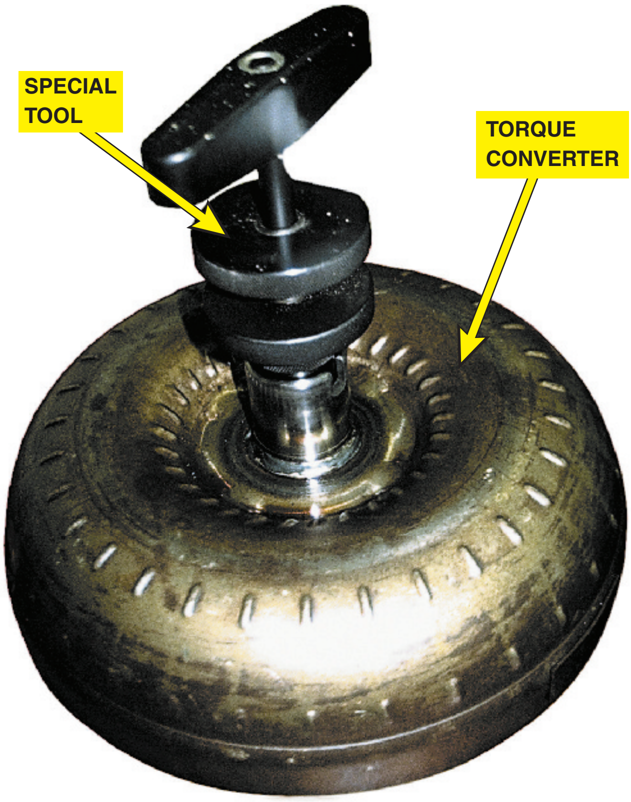

FIGURE 133–6 A special tool being used to check the end play of the stator inside the torque converter.

TECH TIP

Check the Flex Plate

After removing the transmission or transaxle, carefully inspect the flexplate for the following faults:

1. Cracks
2. Warpage
3. Stripped starter ring gear teeth

TECH TIP

Replace the Torque Converter

Many automotive transmission/transaxle experts recommend that the torque converter be replaced when the automatic transmission is rebuilt or replaced. This is because the torque converter is generally considered to be the "garbage pit" of the entire unit in that it often collects wear particles from the clutches and bands that can cause future problems. According to remanufacturers of torque converters, the majority of the torque converters being returned as cores have little, if any, friction material remaining for the torque converter clutch. ● **SEE FIGURE 133–7**.

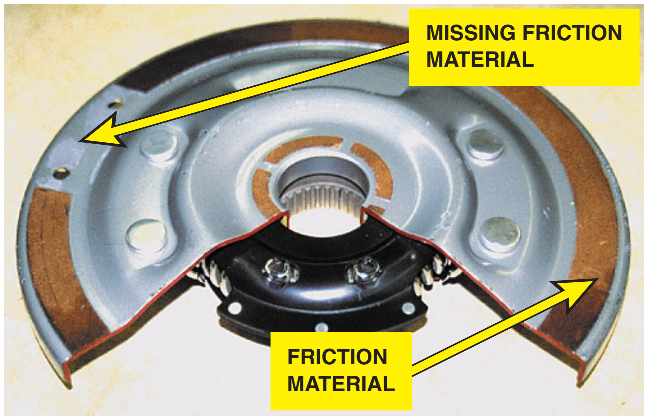

FIGURE 133–7 A cutaway of the torque converter clutch showing the paper-thin friction material.

VALVE BODY Remove the valve body and the internal electronic components found in many units. Before the valve body fasteners are removed, the following items need to be performed or checked:

1. Disconnect the manual valve linkage and "rooster comb."
2. Carefully loosen the valve body bolts starting from the outside and working toward the center or help prevent distortion.
3. Remove the lower part of the valve body.
4. Remove the separator plate. ● **SEE FIGURE 133–8**.
5. Check and note the location of all check balls in the upper valve body.
6. Carefully check the operation of all shift valves by using a plastic tool or compressed air to move the valves in their bores. All valves should be free to move and should return to the home position by spring pressure. ● **SEE FIGURE 133–9**.

To service a valve body, disassemble all the parts, identify them for reassembly, and check the valve body with a precision straightedge.

PUMP ASSEMBLY Remove the pump assembly using the proper removal tool to avoid damaging it. ● **SEE FIGURES 133–10 AND 133–11**.

Check the pump for wear by checking service information for the recommended procedure and specifications. ● **SEE FIGURE 133–12**.

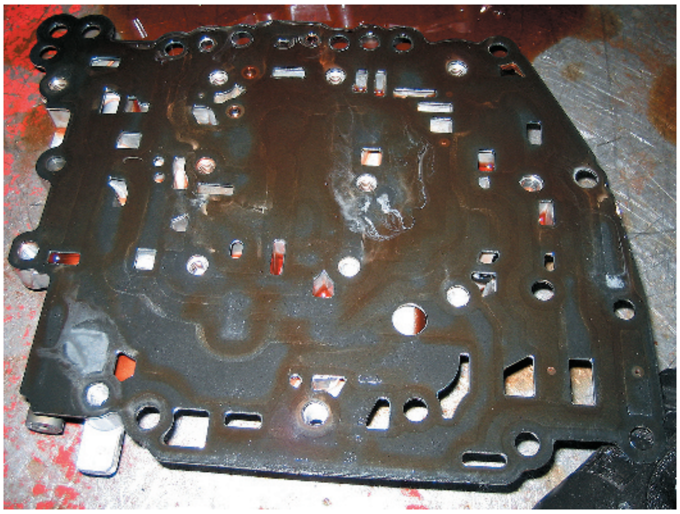

FIGURE 133–8 A typical separator plate. Check holes over check balls to make sure that the metal balls have not caused damage to the separator plate during operation.

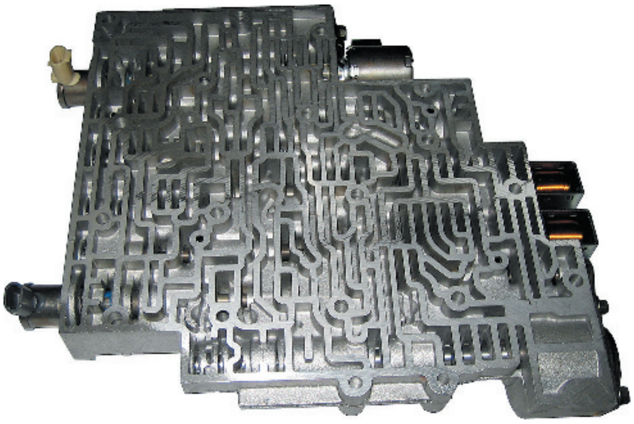

FIGURE 133–9 Check that all valves are free to move, and look for signs that the valves have caused wear to the valve bore. This causes fluid to leak around the valves, which can also cause shifting problems. If the bore is found to be worn, then the valve body will require repair using specialized tools or replacement.

TECH TIP

The Valve Body Cardboard Trick

To help remember where each bolt goes in the valve body, draw an outline of the valve body on cardboard and then stick the bolts through the cardboard in the position where they were removed. Often the lengths of the bolts are different, so this method saves time and helps prevent possible harm to the valve body of the case of the transmission/transaxle when reassembling the unit.

UNIT DISASSEMBLY Before disassembly, measure input shaft end play. Some transmissions require the measurement of output shaft end play. Always check service information for the specified procedures to follow.

The usual disassembly procedure includes

1. Removal of snap rings
2. Compressing of clutch pistons most often using special tools
3. Removal of bands (if equipped)

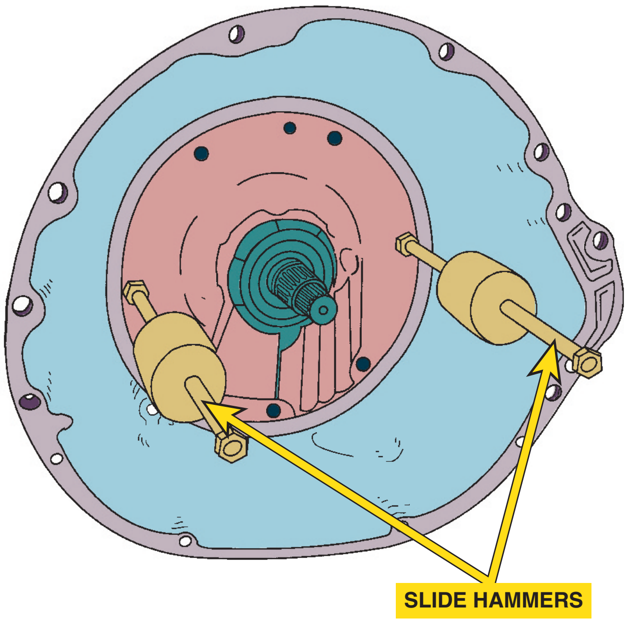

FIGURE 133–10 Two slide hammers are often used to remove a pump from older automatic transmissions.

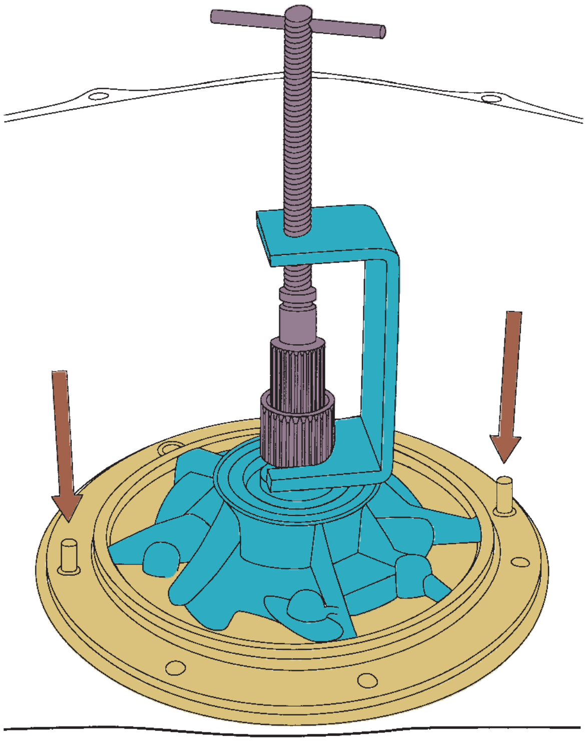

FIGURE 133–11 A special puller is usually specified to remove aluminum pumps from automatic transmission/transaxles. Alignment pins (arrows) are used to properly align the gasket and pump on the case during reassembly.

4. Removal of solenoids
5. Disconnecting and labeling of all interior wiring

Note the condition of all of the following so that any parts needed can be ordered:

- One-way clutches
- Clutches and bands (if used)
- Accumulators and springs
- Trust washers
- Snap rings

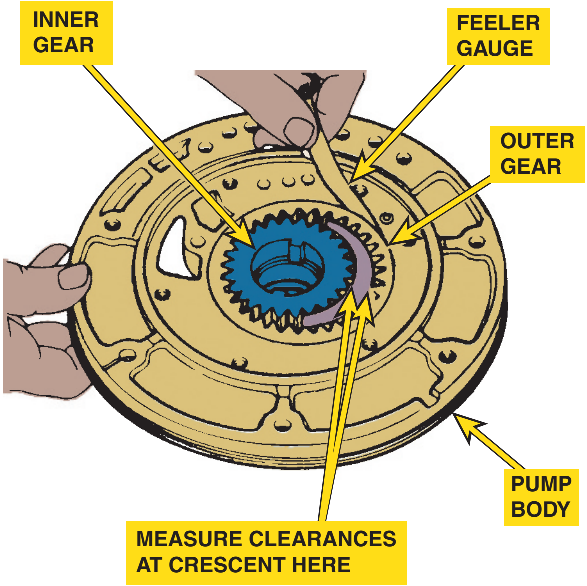

FIGURE 133–12 Checking a transmission pump assembly for wear using a feeler gauge. Compare the reading to factory specifications.

TECH TIP

A Picture Is Worth a Thousand Words

During disassembly, note items such as direction of snap rings front and back and clock position of the snap ring openings. Instead of taking numerous detailed notes, use a digital or phone camera and take pictures as the unit is being disassembled. Then the photos can be reviewed during reassembly to be sure that everything is installed in the same position as it was when it was disassembled.

- Servos and springs
- Planetary gear sets
- Final drive assembly on transaxles
- Shift and pressure control solenoids

Save the old gaskets to match with the new ones. Clean all parts in a solvent that removes all gum, varnish, dirt, and grease. Rinse clean parts in hot, running water, and then immerse them in clean mineral spirits or a similar solvent to separate water from the parts. Finish cleaning by blow drying with low-pressure, filtered, compressed air. Once clean, inspect the valve body and its components for the following:

- Scored, cracked, or burred plugs and valves
- Broken, bent, or worn springs
- Scored or rusted bores
- Plugged or restricted fluid passages
- Bent or rusted separator plates
- Stuck check valves
- Bent manual valves
- Cracked castings and distorted or nicked mating surfaces.

Shiny areas on valve lands indicate friction between the spool valve and body. On steel valves, these areas can be polished carefully with 400- to 600-grit wet or dry sandpaper, crocus cloth, or polishing stone. Take care not to round off the edges of the valve lands while polishing. Aluminum valves cannot be polished. If a valve needs polishing, the bore it rides in also requires servicing. Polish the valve bore by inserting and turning loosely rolled wet or dry sandpaper or crocus cloth. Attach a piece of crocus cloth to a slotted dowel rod or bent welding rod to reach the bottom of a deep bore. Rewash and dry any valves and bores that are polished.

After polishing and washing, lubricate the spool valve with ATF and slide it into its bore to check fit and operation. The valve should slide back and forth freely of its own weight.

CAUTION: Do not use cloth shop cloth as lint can cause a sticking shift valve.

CLUTCH PACKS Begin disassembling a clutch pack by removing the snap ring that holds the discs in the housing. Remove the snap ring from most clutches by prying one end of it free from its groove with a small screwdriver. Then, slide the screwdriver around the drum and the snap ring removes easily. ● **SEE FIGURE 133–13**.

FRICTION DISC INSPECTION Wipe each friction disc with a dry, lint-free cloth and inspect for the following:

- Excessive wear
- Cracks in the lining material
- Charred, burned, or glazed lining surface
- Pitting, flaking, or scoring
- Chips or particles embedded in the lining
- Scoring or burns on disc serrations
- Distortion and/or warping

Friction discs tend to discolor in use, which is normal. However, if any friction disc shows signs of one or more of the defects above, replace the entire set. Replace the set of friction discs if they do not fit freely in the clutch hub serrations (grooves) or if there is wear or damage to their splines.

STEEL DISC INSPECTION Clean steel discs by wiping with a dry, lint-free cloth and, once clean, inspect each disc for the following:

- Uneven heat discoloration
- Surface scuffing or scoring

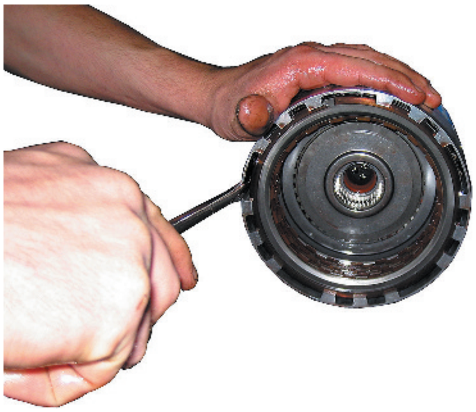

FIGURE 133–13 A straight-blade screwdriver can help remove the snap ring that is used to retain the frictions and steels in the clutch pack.

- Drive lug damage
- Distortion and/or warping

Replace the entire set of steels if you note a rough surface or there is uneven or spotty discoloration on any of the discs. Also replace steel discs if they do not fit freely into the clutch drum tang notches.

CLUTCH PISTON REMOVAL AND INSPECTION To remove the snap ring holding the clutch piston in place, compress the piston return springs using the proper compressor tool. Always check service information for proper procedure. ● **SEE FIGURE 133–14**.

Tightening a nut onto the shaft draws the fingers of the tool down, compressing the spring, and allowing the snap ring to be

TECH TIP

Smooth Is In; Rough Is Out

It used to be common practice in the automatic transmission business for the rebuilder to use sandpaper to "roughen up" the surface of the steel discs to achieve a good clutch apply. This is not true now. Sanding creates grooves and sharp peaks that decrease the oil film between the paper on the friction plate and the steel plates. There should be a thin oil film between the paper and the steel to create a holding bond and make it possible for a clutch pack to apply and release thousands of times without wear. Therefore, for consistent shifts and a long-lasting transmission/transaxle, do not sand the steel discs. Steels are often replaced with new steels along with new friction discs during an overhaul.

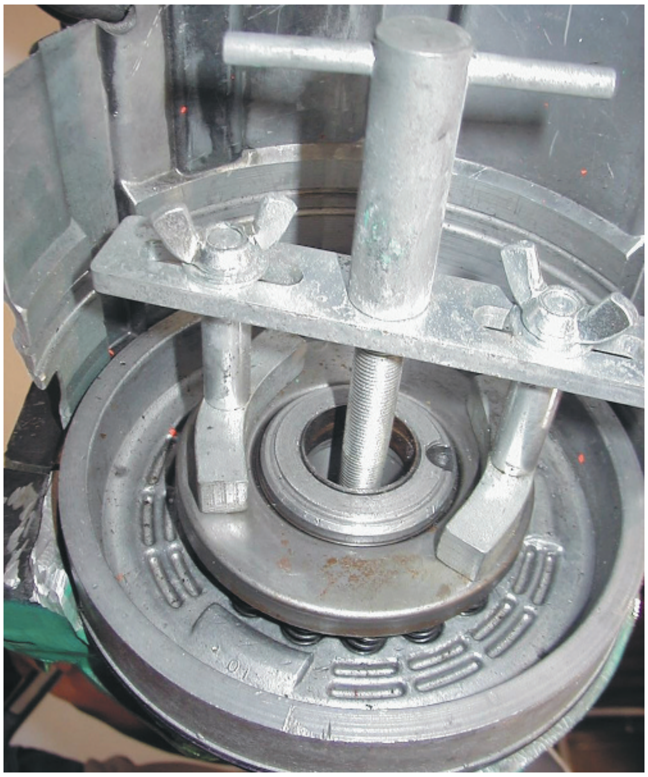

FIGURE 133–14 A compressor tool is usually necessary to compress the springs of the clutch piston to remove the snap ring.

removed. After removing the snap ring, release and remove the spring compressor, then remove and inspect the return springs.

RETURN SPRING INSPECTION Coil springs should be straight and provide proper pressure. Check for broken, distorted, or collapsed springs. If one or more of the springs requires replacement, discard them all and install a complete set of new springs.

NOTE: Individual return springs are often colored coded as to their location. Make note of the color and number of return springs for ease of reassembly.

Some coil springs are permanently attached to their retaining collar and can only be serviced as a set. There will be vacant spring seats in some applications. This allows the manufacturer to use the same piston but vary the number and location of springs to precisely match spring return rate to the requirements of a particular vehicle. In these cases, reinstall return springs in exactly the same location.

CLUTCH PISTON INSPECTION Remove the clutch piston from the hub. The drag of the piston seal can make it hard to remove the piston from its bore. Should this be the case, apply low-pressure compressed air through the hydraulic apply hole in the housing to force the piston from its bore.

CAUTION: Always use care when using compressed air as it can be very dangerous. Use regulated air pressures set to a maximum 35 PSI (240 kPa) and a rubber-tipped nozzle. Always wear safety glasses when checking valves and actuators using compressed air.

Do not use high air pressure and be careful to avoid pinching your hand or dropping the piston as it pops from its bore. Once you remove the piston, check for the following:

- Cracks or scoring in the piston bore
- Nicks, scores, burrs, or signs of wear on the piston
- Seal damage
- Fluid passage obstructions or restrictions

If the piston contains a check valve, make sure it is functional. Remove and discard seals.

HUBS, DRUMS, SHELLS, AND PLANETARIES Clutch hubs, drums, and shells transfer the torque load to the various combinations of planetary gear set members to provide different gear ratios. Hubs, drums, shells, and planetaries are *hard parts* that do not wear out under normal conditions, so they can be reused unless they are damaged. ● **SEE FIGURE 133–15**.

Carefully check drums and shells for cracks before reusing. Wash with solvent, dry with compressed and filtered air, and then inspect. Planetary gear sets should be checked for proper pinion gear end play and compared to factory specifications. ● **SEE FIGURE 133–16**.

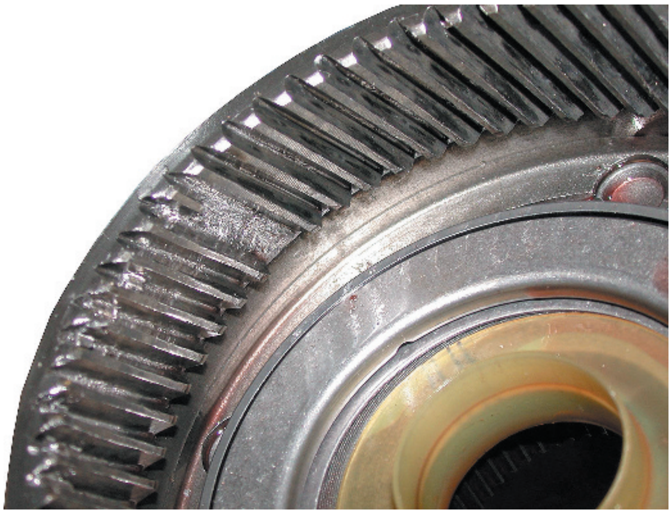

FIGURE 133–15 The ring gear has damaged gear teeth. This entire planetary gear set must be replaced because the damage also affected the gear teeth of the planetary pinion gears and the sun gear.

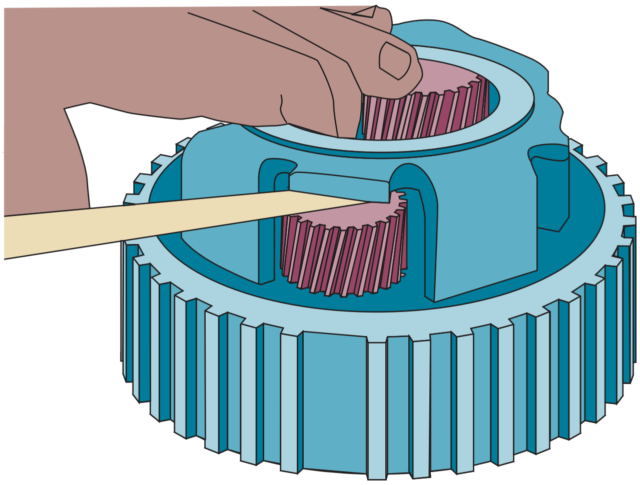

FIGURE 133–16 Pinion gear end play can be checked using a feeler gauge.

REASSEMBLING AN AUTOMATIC TRANSMISSION/ TRANSAXLE

CLUTCH ASSEMBLY Before assembling a clutch assembly, soak all friction plates in automatic transmission fluid (ATF). This should be done for as long as possible to allow the friction material to absorb the automatic transmission fluid. Check service information for the exact order of assembly and assemble each clutch pack.

AIR PRESSURE CHECKS Reassembly of an automatic transmission/transaxle involves assembling the various subassemblies, such as a clutch pack clearance, before final assembly is completed. ● **SEE FIGURES 133–17 AND 133–18**.

If the clutch pack clearance is not correct, often one clutch pack component is a selective member. The selective component could be any of the following:

- Reaction plate
- Pressure plate
- Thrust washer
- Snap ring

After making the needed changes, the clearance should be rechecked to be sure it is within factory specifications.

An **air pressure check** uses air to apply clutches and/or bands to verify that components such as clutch packs perform correctly. The air takes the place of the ATF under pressure when

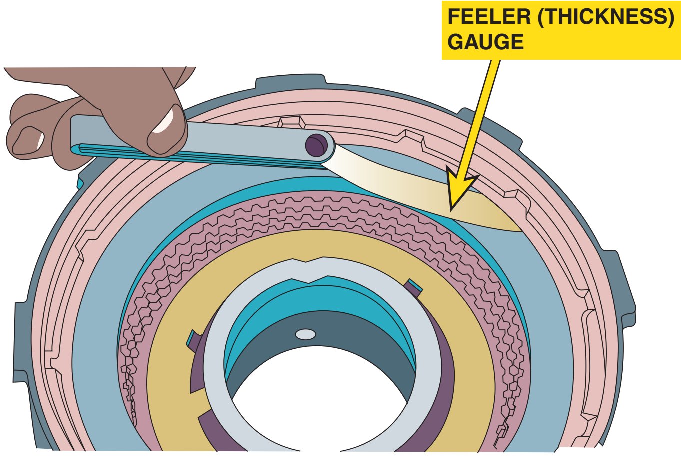

FIGURE 133–17 All clutch packs should be checked for proper clearance. Here, a feeler (thickness) gauge is used to check the clearance to make sure it is within factory specifications.

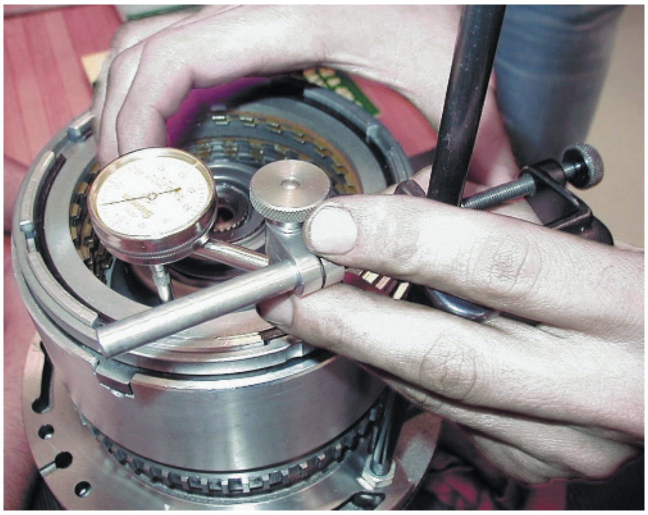

FIGURE 133–18 Checking clutch pack clearance using a dial indicator. This method is used when a feeler gauge cannot be inserted to check for proper clearance.

it is being used in the vehicle. Air checking a unit includes the following steps:

STEP 1 Use the factory service information regarding where to air check and what the results should be.

STEP 2 Use a rubber-tipped air nozzle and regulate the air supply to about 35 PSI (240 kPa).

STEP 3 A typical result is a dull thud or clunk heard when air pressure is applied to a clutch pack or servo piston. ● **SEE FIGURE 133–19**.

STEP 4 When the air pressure is removed, the unit should release. If there is a seal leak, air can usually be heard hissing from around the seal. ● **SEE FIGURE 133–20**.

BUSHINGS All bushings should be inspected and replaced if necessary. ● **SEE FIGURE 133–21**.

ONE-WAY CLUTCHES Always double check that all one-way roller clutches are installed correctly. The transmission will not work correctly if the one-way clutch is installed upside down. Check service information for the exact method to use to ensure that they are installed correctly. ● **SEE FIGURE 133–22**.

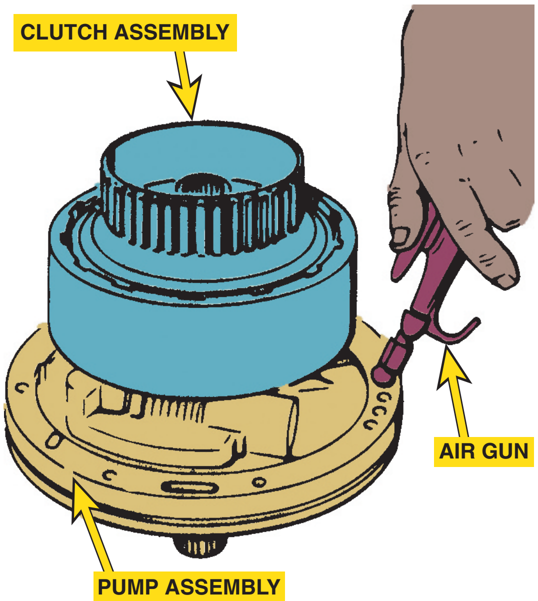

FIGURE 133–19 Air testing a clutch pack before installing it into an automatic transmission or transaxle.

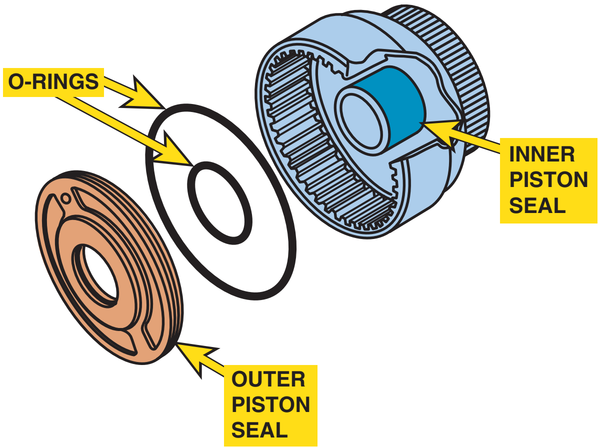

FIGURE 133–20 Both the inner and outer seals are checked when air testing a clutch pack assembly.

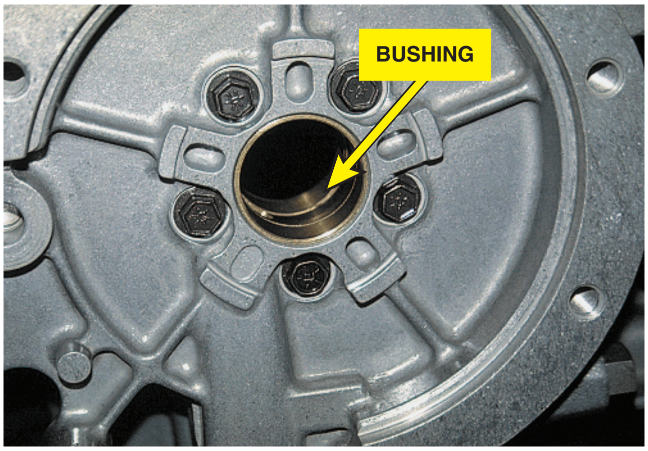

FIGURE 133–21 A typical brass bushing used in an automatic transmission.

SPECIAL TOOLS Special tools are often specified by the vehicle manufacturer. These tools allow the service technician to disassemble and reassemble the transmission/transaxle more easily without harming the unit. ● **SEE FIGURE 133–23**.

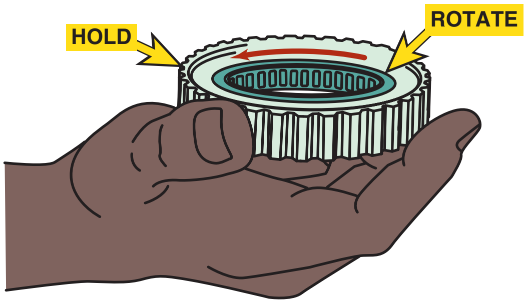

FIGURE 133–22 Service information states that this one-way roller clutch should be installed as shown. Check by holding the outer race so that the inner race is free to rotate counterclockwise as shown.

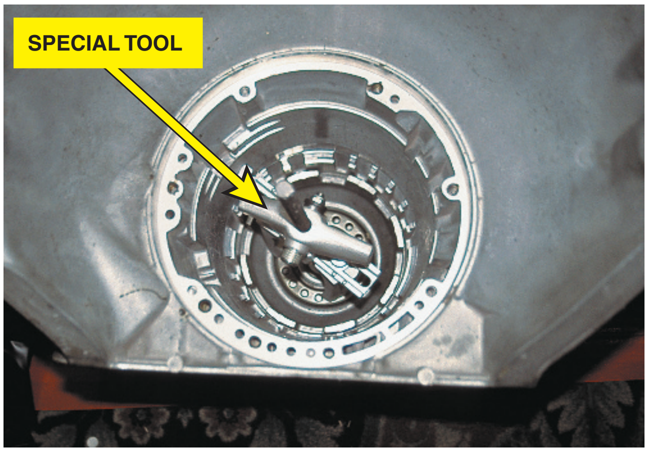

FIGURE 133–23 A special clamp makes removal and reinstallation of this clutch pack easier.

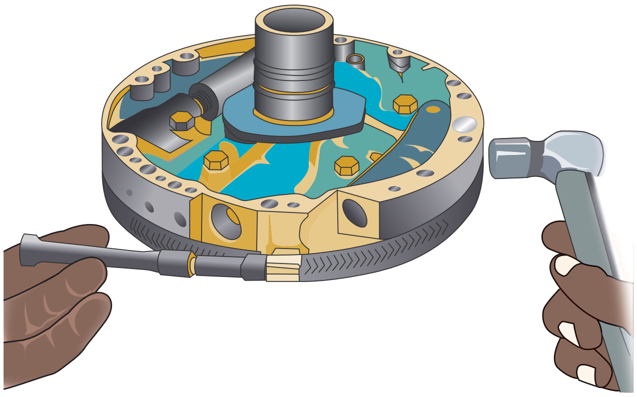

FIGURE 133–24 Using an alignment clamp to assemble both pump halves. To ensure proper alignment, many experts recommend lightly tapping the outer edges of the pump while tightening the clamp.

PUMP ASSEMBLY Follow the vehicle manufacturer's recommended procedures. For example, a special clamp is often necessary to properly assemble a pump. ● **SEE FIGURE 133–24**.

END PLAY CHECKS Perform all end play checks during assembly to ensure that the unit was properly assembled and that the proper internal clearances are achieved. ● **SEE FIGURE 133–25**.

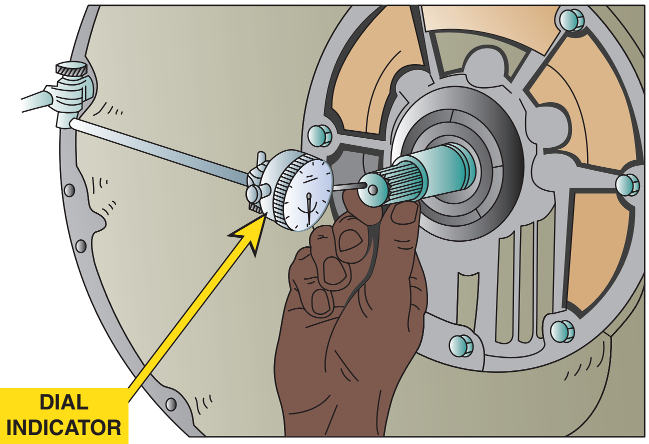

FIGURE 133–25 A dial indicator being used to measure the end play of an input shaft. If the end play is not within factory specifications, the unit may not have been assembled correctly.

TECH TIP

Avoid Using Red Assembly Lube

Assembly lube is used during the reassembly of automatic transmissions. If red assembly lube is used on seals, it may look like an automatic transmission fluid leak when the transmission gets hot and the lube melts. If you use blue, green, brown, or clear assembly lube, then the color will immediately identify it as assembly lube. ● **SEE FIGURE 133–26**.

Many transmissions have been disassembled because the service technician thought that the red liquid dripping from parts of the transmission was automatic transmission fluid when, in fact, it was only assembly lube that melted and ran when the transmission reached normal operating temperature.

FIGURE 133–26 Blue assembly lube.

VALVE BODY CHECKS The valve body can be checked using a tester especially designed for this purpose. Adapters are available for all commonly serviced automatic transmissions/transaxles, and the pressure gauges that are part of the tester are used to monitor the movement and flow through the valve body.

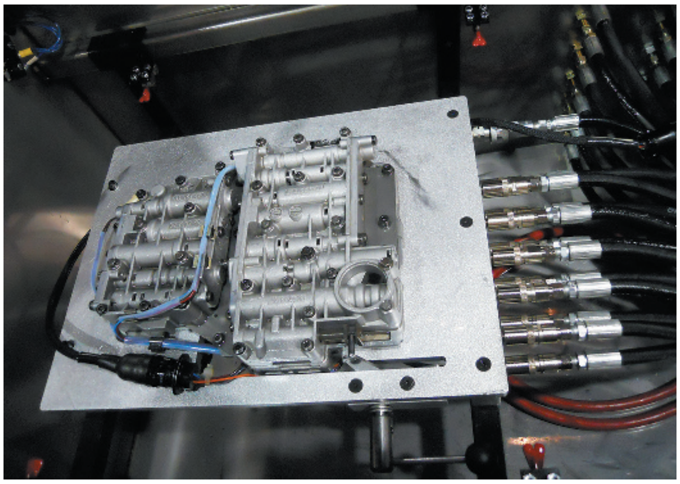

FIGURE 133–27 A valve body being tested on a valve body tester. While it takes some setup time to adapt each valve body to the proper hoses, this type of machine can find valve body problems before the transmission/transaxle is installed in the vehicle.

TECH TIP

Change the Bolts and Washers

When reassembling an automatic transmission, always replace the pump bolts and sealing washers to avoid the possibility of a leak. A leak in the area of the pump can cause quite a headache for the technician because the entire assembly must be removed from the vehicle again to fix it.

This unit also heats the automatic transmission fluid so that the valve body is being tested under the same conditions as will be occurring in the vehicle. It is easier to repair a fault with the valve body than wait until the valve body and the transmission are installed in the vehicle. ● **SEE FIGURE 133–27**.

CAUTION: It is critical that the valve body be torqued in the proper sequence to the correct specification to avoid warpage which could cause a sticking valve.

FLUSHING THE COOLER AND TORQUE CONVERTER

PURPOSE All vehicle manufacturers recommend that the automatic transmission fluid cooler be checked for proper flow and, if not, then it should be replaced whenever a replacement or overhauled automatic transmission/transaxle is installed in a vehicle. Most vehicle manufacturers are recommending to flush the cooler. Cooler can be flushed using special machines that pulsate ATF through the cooler. Solvent can be used to clean the varnish that flushing with ATF will not remove. Always follow the instructions that come with flushing machines or solvent containers.

NOTE: At least 2 quarts (liters) of ATF should flow through the cooler every 30 seconds or the cooler and/or the lines are restricted. ● SEE CHART 133–1 for the placement of the cooler-out lines on common transmissions/transaxles.

The location of the cooler-out lines varies by vehicle and transmission/transaxle. Check service information for location of the cooler lines on the vehicle being serviced.

DYNAMOMETER TESTING THE AUTOMATIC TRANSMISSION/TRANSAXLE

A rebuilt automatic transmission/transaxle can be tested on a dynamometer powered by

- An electric motor (● **SEE FIGURE 133–28.**)
- A gasoline engine (● **SEE FIGURE 133–29.**)

Most dynamometers are equipped with pressure gauges so the operation of the unit can be checked before being installing in the vehicle.

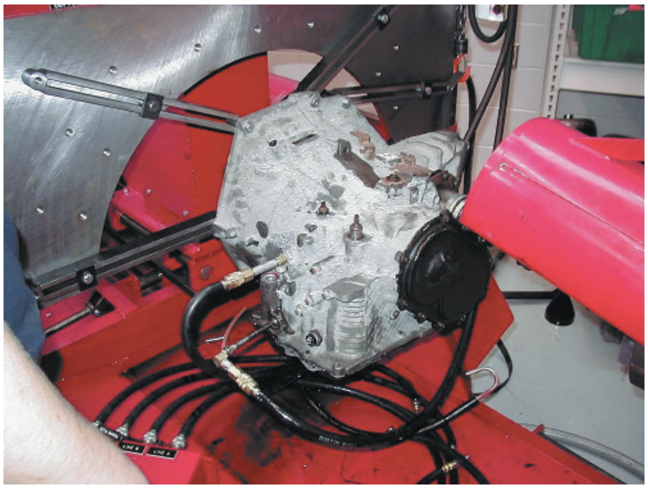

FIGURE 133–28 An electric motor-driven dynamometer being used to check the operation of a 41 TE transaxle.

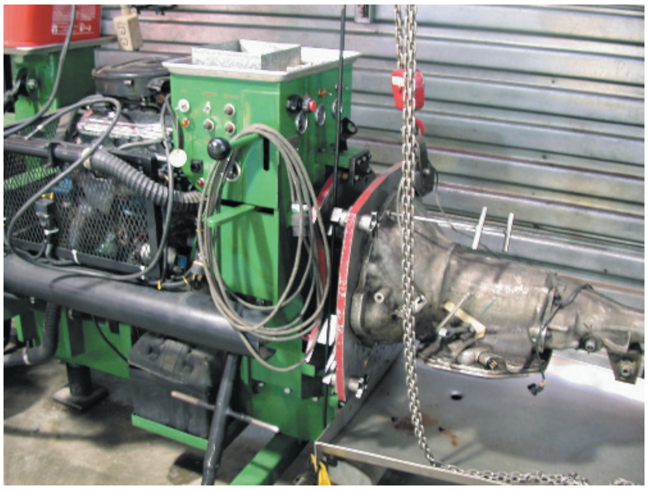

FIGURE 133–29 A gasoline-powered dynamometer being used to test a rear-wheel-drive automatic transmission.

REINSTALLING THE AUTOMATIC TRANSMISSION/TRANSAXLE

DOUBLE CHECK END PLAY After the unit has been reassembled and all end play checks indicate that the unit is properly assembled, reinstall the automatic transmission/transaxle in the vehicle. Many experts recommend that new transmission/transaxle mounts be installed to assure proper driveshaft/drive axle shaft angles.

NOTE: New mounts are particularly important if the unit was leaking automatic transmission fluid (ATF). The ATF can soften and deteriorate the rubber used in the mounts.

TORQUE CONVERTER INSTALLATION Before installing the unit into the vehicle, flush the torque converter with clean ATF. Carefully install the torque converter onto the input shaft being sure to fully engage the following:

- Pump gear
- Stator splines
- Turbine splines

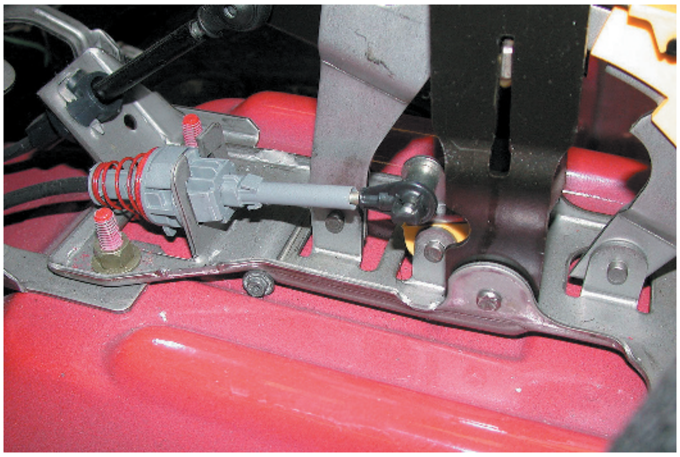

FIGURE 133–30 Check the linkage for proper adjustment so that the shift interlock works correctly and the PRNDL is aligned with the transmission range switch.

TRANSMISSION/TRANSAXLE INSTALLATION Check service information for the exact procedure to follow when installing an automatic transmission/transaxle. The following are the steps often specified:

- inspect engine core plugs and replace as required.
- Check and replace as needed the rear crankshaft seal.
- Check and correct as needed the dowel pins, dowel pin holes on the back of the engine block.
- Check the engine to transmission mounting surfaces.
- Carefully install the unit and use a torque wrench to torque the bolts to the bell housing.
- Attach the torque converter to the flex (drive) plate.
- Reattach all electrical connections, linkages, and cooler lines. ● **SEE FIGURE 133–30**.
- Lower the vehicle and add enough ATF to properly fill the unit. Consult factory information for the recommended amount, to avoid under- or overfilling.

ROAD TEST

FAST LEARN THE PCM/TCM Start the engine and check the level of the ATF. For an electronic transmission/transaxle to operate correctly, a "fast learn" or a "quick learn" should be performed

TECH TIP

Install a Transmission Cooler

An auxiliary transmission fluid cooler is recommended by most experts to help keep the temperature from becoming excessive, especially when towing or performing other heavy-duty vehicle operation. ● **SEE FIGURE 133–31**.

Most experts recommend that the cooler be connected so that the hot fluids travel through the auxiliary cooler and then through the factory cooler and return to the transmission/transaxle. Using this method of plumbing allows the radiator to warm the transmission fluid in cold weather as well as provide additional cooling of the fluid when the fluid temperature is high.

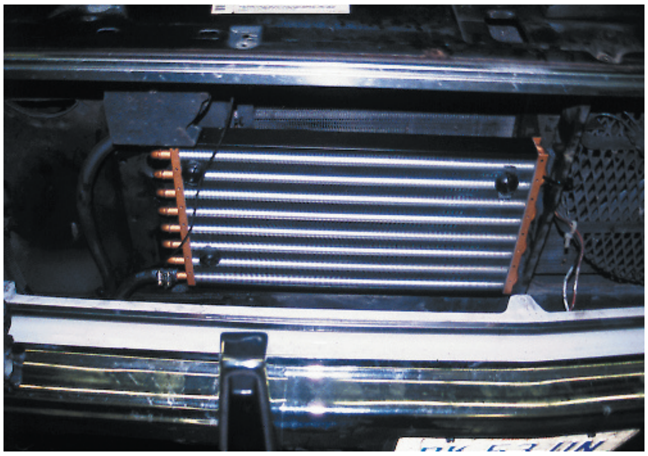

FIGURE 133–31 An auxiliary automatic transmission fluid cooler installed on a Chevrolet pickup truck used to haul a car trailer.

with a scan tool before the vehicle is driven. This action will get the adaptive settings close to what they should be and will help prevent damage to the unit if this procedure is not done.

TECH TIP

If the Torque Converter Is Dropped, Replace It

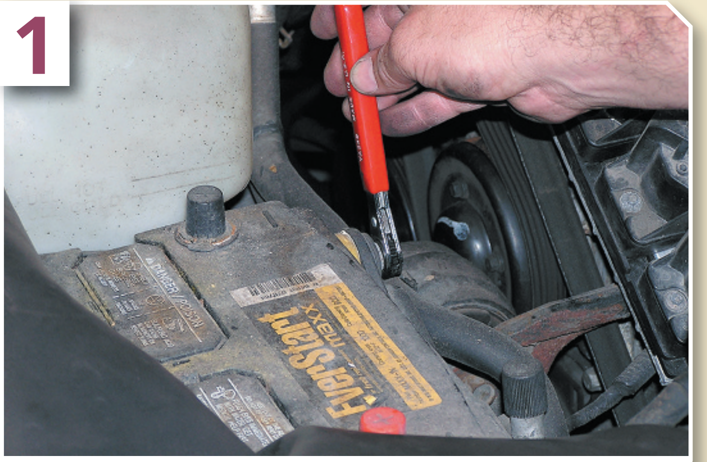
Torque converters include plastic thrust plates, which are very strong under the compressive forces of normal torque converter operation. However, if a torque converter is dropped, even from a distance of less than 6 inches (15 cm), the thrust washer can easily break, ruining the torque converter. Even though torque converts look strong and feel heavy, handle them as if they are glass.

In addition, Chrysler has a torque converter burnishing mode that can be activated on the scan tool for some models.

ROAD TEST PROCEDURE Carefully test drive the vehicle, checking for proper operation and shift points. Hoist the vehicle and check for any possible ATF leaks before returning the vehicle to the customer.

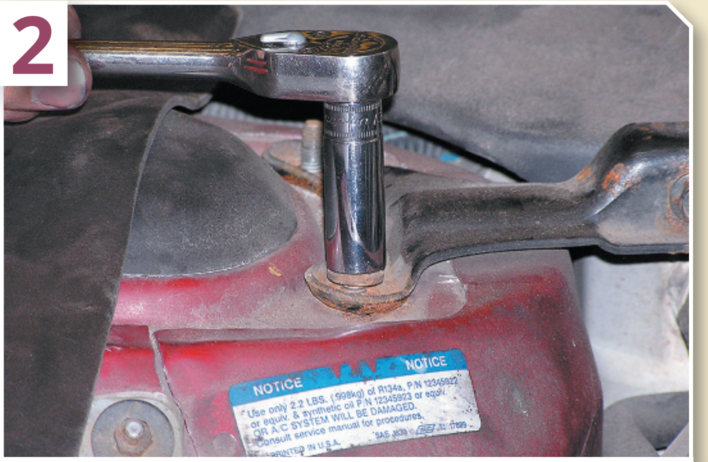
TRANSAXLE REMOVAL

1



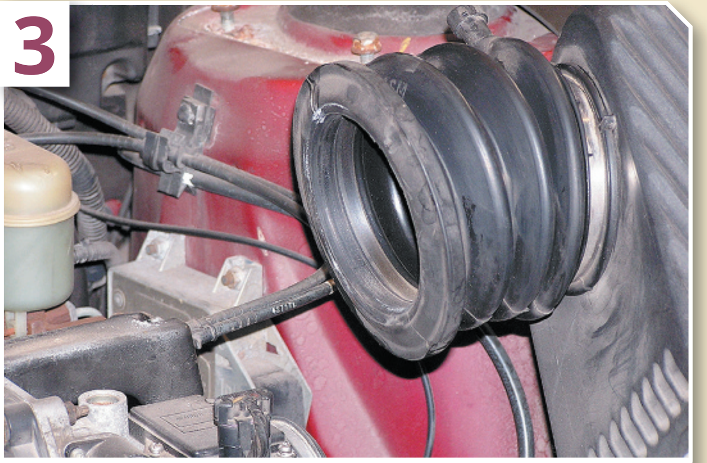
For safety purposes, remove the negative battery cable before starting the removal procedure.

2



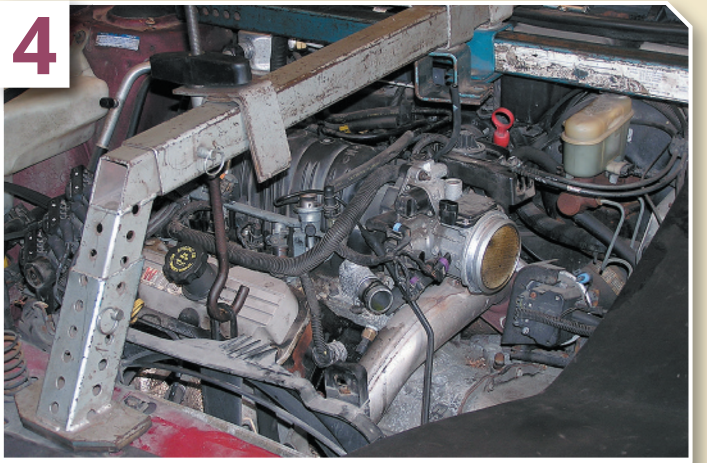
Remove engine bay cross members that may interfere with access to the transaxle fasteners.

3



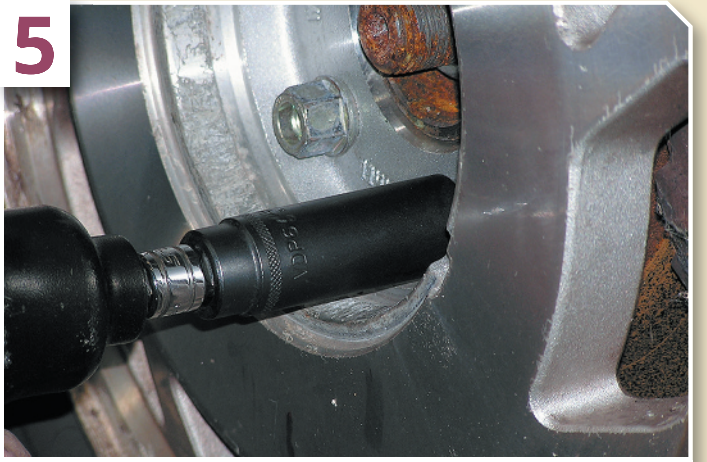
Remove the air intake and air filter assembly, which is covering the transaxle in this vehicle.

4



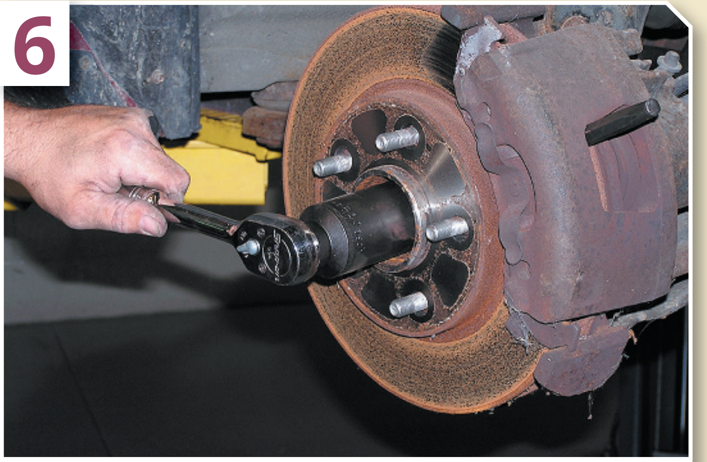
Install a support for the engine.

5



Safely hoist the vehicle and remove the wheels.

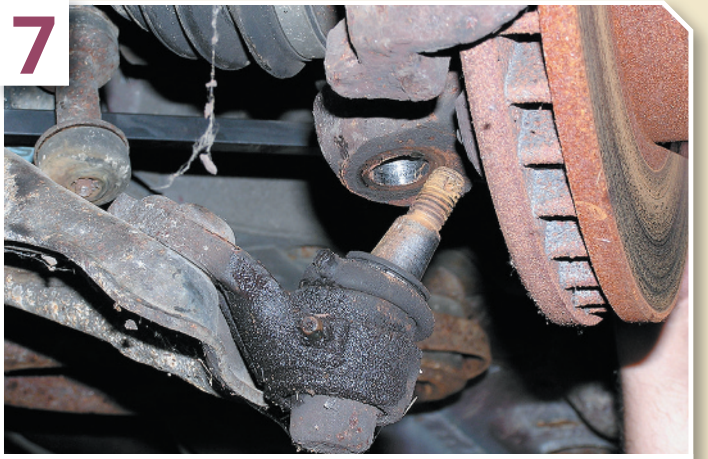
6



Remove the retaining nut from the drive axle shaft.

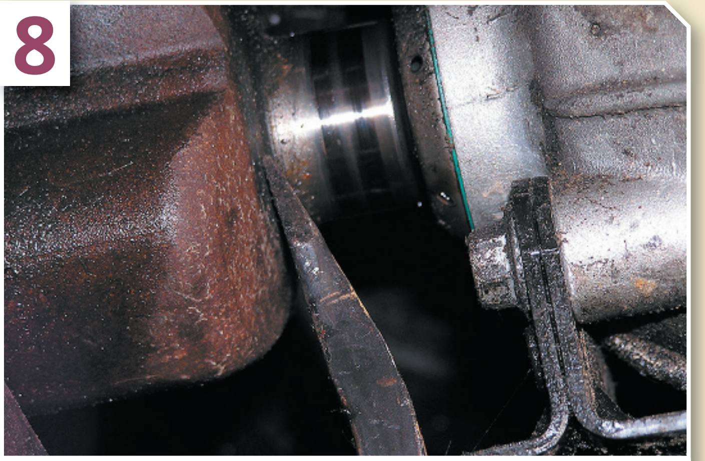
STEP BY STEP

7



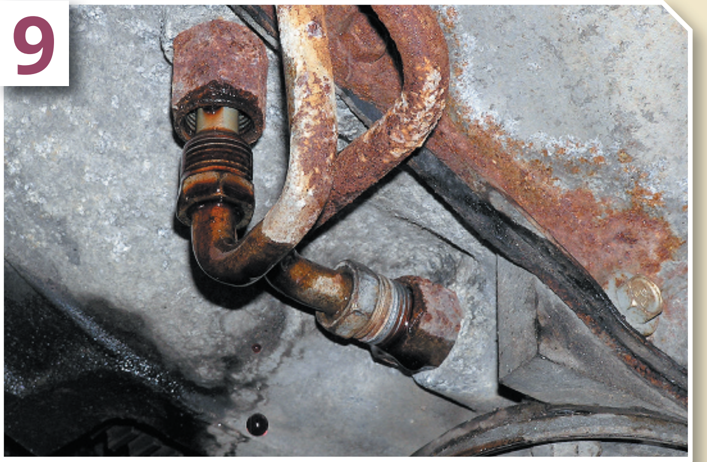
Disconnect the lower ball joint on the front-wheel-drive vehicle to allow removal of the drive axle shaft.

8



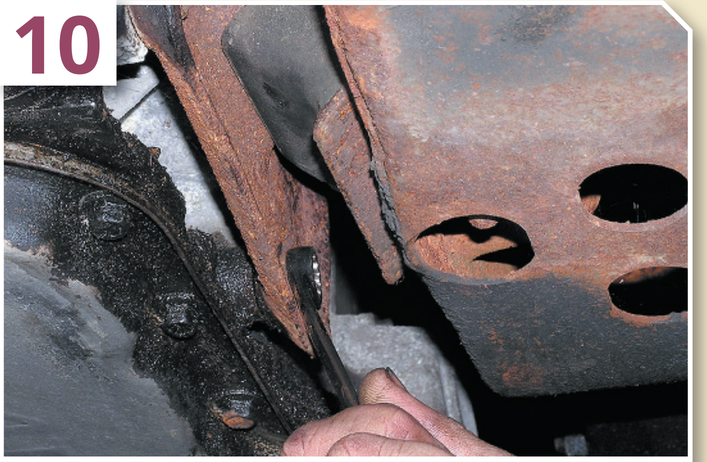
Remove the drive axle shaft from the transaxle using a pry bar.

9



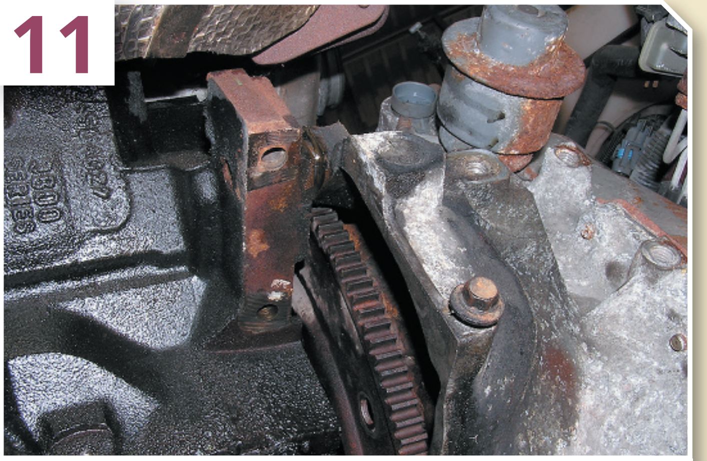
Disconnect the cooler lines from the transaxle using a line wrench.

10



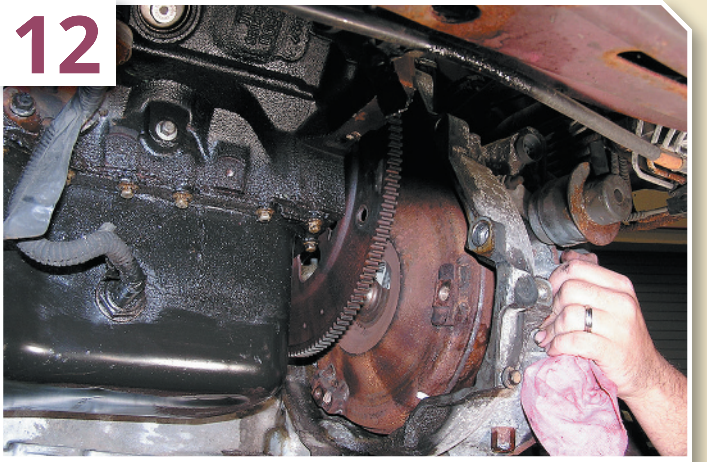
Unbolt the torque converter from the flexplate, then remove the transaxle mounts.

11



With the transaxle supported on a transmission jack, remove the retaining bolts from the bell housing.

12



Carefully remove the transaxle from the vehicle.

REVIEW QUESTIONS

1. What are the typical operations needed when disassembling an automatic transmission/transaxle?
2. What are two methods of checking a clutch pack?
3. Why is it important to perform an end play check of an automatic transmission/transaxle during the reassembly process?
4. Why is it important to flush the automatic transmission fluid cooler when a rebuilt or replacement automatic transmission/transaxle is being installed in a vehicle?
5. Why should assembly lube NOT be red in color?

CHAPTER QUIZ

1. The technician should use ___________ to verify the need for unit repair.
   - **a.** service information
   - **b.** the owner's manual
   - **c.** the parts catalog
   - **d.** Any of the above
2. What is the first step required when removing an automatic transmission or transaxle?
   - **a.** Remove the pan so all of the fluid is drained from the unit
   - **b.** Disconnect the negative battery cable
   - **c.** Disconnect the torque converter from the flexplate
   - **d.** Remove the cooler lines
3. Friction discs should be ___________ before being installed.
   - **a.** sanded
   - **b.** soaked in ATF
   - **c.** surface roughed up
   - **d.** All of the above
4. Technician A says that the torque converter should be separated from the flex (drive) plate before removing the automatic transmission/transaxle. Technician B says that the clutches should be installed “dry” when replacing the frictions and steels in a clutch pack. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
5. Air pressure checking is used to test ___________.
   - **a.** clutch packs
   - **b.** transmission filters
   - **c.** TCC solenoids
   - **d.** shift valves
6. Technician A says that all friction and steel plates in a clutch pack should be replaced during an overhaul. Technician B says that the automatic transmission fluid cooler should always be flushed when a unit is rebuilt or replaced. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
7. Which of these requires transmission removal if it needs to be replaced?
   - **a.** Range switch
   - **b.** Speed sensors
   - **c.** Valve body
   - **d.** Converter clutch
8. Most dynamometers are equipped with ___________ so the operation of the unit can be checked before being installed in the vehicle.
   - **a.** pressure gauges
   - **b.** a drive shaft
   - **c.** a powertrain control module (PCM)
   - **d.** All of the above
9. How much transmission fluid should flow through the cooler?
   - **a.** 2 quarts every 30 seconds
   - **b.** 1 quart per minute
   - **c.** 2 quarts per minute
   - **d.** 2 pints per minute
10. Road testing the vehicle should include ___________.
    - **a.** performing a fast learn procedure
    - **b.** checking for proper shifting
    - **c.** checking for any leaks
    - **d.** All of the above

PARTS SPECIALIST (P2)

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Discuss the terminology of a typical automotive parts business.
- Discuss the general operations of a typical automotive parts business.
- Describe the customer relations and sales skills needed by a parts specialist.
- Explain how to identify a vehicle, including the VIN, body style, and paint codes.
- Demonstrate basic knowledge of the systems common to every vehicle.
- Describe catalog and information system skills that a parts specialist must have.
- Explain inventory management, including physical inventory, stock rotation, and parts returns.
- Describe merchandising strategies.

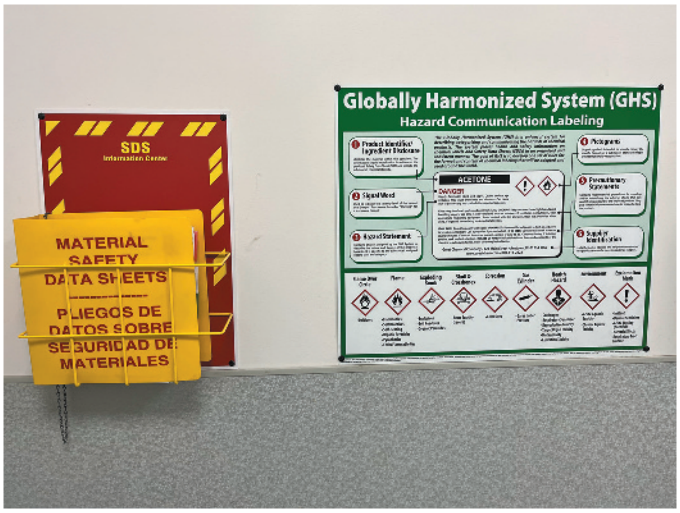
DEFINITIONS AND TERMINOLOGY

PARTS SPECIALIST Automotive parts specialists must learn the skills needed to work competently in a retail or jobber parts store. Automobile parts specialists must possess knowledge about a wide range of vehicle component systems for all makes and models. They must also have customer relations, sales, merchandising, vehicle identification, cataloging, and inventory management skills.

OEM PARTS **Original equipment manufacturer (OEM) parts** are manufactured by the same company that produced the original part used in assembly of the vehicle. Vehicle dealer parts departments carry OEM parts as well as some parts and supplies manufactured by other companies.

JOBBER PARTS **Jobber parts** (or **aftermarket parts**) are not made by the original manufacturer of the vehicle. The aftermarket industry makes up about 80% of the parts used in vehicle repair. A jobber store purchases manufacturer goods at wholesale prices, usually through a **warehouse distributor** and then sells products to consumers at retail prices.

OSHA The U.S. Congress passed the **Occupational Safety and Health Administration (OSHA)** act into public law in 1970.



Globally Harmonized System (GHS)
Hazard Communication Labeling
SDS
Information Center
MATERIAL SAFETY DATA SHEETS
PLIEGOS DE DATOS SOBRE SEGURIDAD DE MATERIALES

FIGURE 134–1 The SDS and Globally Harmonized System (GHS) information are displayed in a parts store. The GHS includes health, physical, and environmental hazards as well as SDSs.

Workers must be familiar with OSHA standards regarding health and safety in the workplace.

SAFETY DATA SHEETS (SDS) A **Safety Data Sheet (SDS)** is provided by manufacturers for all chemicals used in industry. The SDS includes warnings and precautionary information about hazardous materials. OSHA requires that SDSs "shall be maintained and kept in a readily accessible area." Any SDSs received with shipments or received separately should be placed in a local SDS binder or file. ● **SEE FIGURE 134–1.**

PARTS INDUSTRY TERMINOLOGY The parts industry has many terms relating to ordering, stocking, selling, or returning parts:

- The **invoice** lists all parts by name and is used to track inventory and purchases for billing purposes.
- A **purchase order (PO)** is used to enable a store or business to purchase parts. It describes the component and the quantity being purchased along with billing information.
- A **stock order** is used to order more parts from the supplier on a routine basis.
- A **backorder** is for parts ordered from a supplier but not shipped due to them being out of stock.

GENERAL PARTS OPERATIONS

DISCOUNTS, PRICES, AND PERCENTAGES Businesses often offer discounts and special sales to promote customer interest. Parts specialists might be expected to calculate such discount. A discount is often expressed in percentages such as "20% off." To calculate the percentage discount, perform the following steps:

STEP 1 Convert the percentage to a decimal number by moving the decimal two places to the left. For example, 5% becomes 0.05 and 20% becomes 0.20.

STEP 2 Multiply this decimal number by the price to get the amount of the discount. 20% of $50 = $10 (or 0.20 × $50).

STEP 3 Subtract $10 from $50 to get the discounted price of $40.

FREQUENTLY ASKED QUESTION

How Is Margin Determined?

All businesses must earn money from every sale in order to pay their employees, rent on the building, as well as insurance and other expenses. It is typical in the automotive parts business for each level in the parts distribution chain to earn a 35% (or higher) margin on the parts handled. For example, take a part that costs the manufacturer $5 to produce:

- **First level** The manufacturer needs to make money and sells the part to a warehouse distributor for $10 (50% margin).
- **Second level** The warehouse distributor sells the part to a parts store and adds its markup, usually 35%. To determine what the parts store pays, divide $10 by 0.65. This equals $15.38.
- **Third level** The parts store wants to make a 35% margin, so the cost that it paid ($15.38) is divided by 0.65 = $23.66, which is a 35% margin. This $23.66 is the price that retail customers pay for the part.

This formula works for all amounts.

Percentages are also used to calculate the markup value of parts being sold. If the cost is $55 and the percentage of markup is 10%, then multiply 55 × 10% = $60.50.

NOTE: Financial calculators and computers can handle these calculations, and most likely the store's system will perform these calculations automatically.

SPECIAL ORDERS AND STOCKING FEES A **special order** is placed whenever a customer purchases a part that the business does not normally keep in stock. A customer who places a special order may be asked to pay shipping or handling charges, which may be based on the purchase price. If a customer returns a part, a **stocking fee** may be charged based on the original purchase price. For example, if a customer returns a $50 component and is charged a 5% restocking fee, 5% of $50 is $2.50 and subtracting $2.50 from $50 equals $47.50.

UNIT CONVERSIONS AND MEASURING Parts specialists should have a working knowledge of units of measurement, measuring, and converting from conventional to metric units. For example, engine displacement can be specified in either cubic inches or liters. Converting liters to cubic inches or cubic inches to liters is performed by dividing the volume value of cubic inches by 61 (liters = cubic inches/61).

A ruler, dial caliper, or micrometer might be needed to verify the size and fit of a replacement part, so parts specialists should know how to use and read these tools.

ALPHA, NUMERIC, AND ALPHANUMERIC SEQUENCES An alphanumeric listing is a series of numbers and letters starting from the left digit and working across to the right. If the part numbers are the same but there are slightly different versions of the part, then the order sequence might continue with an A, B, C suffix.

CASH, CHECKS, AND CREDIT/DEBIT/GIFT CARDS Cash sales are more profitable than credit card sales because there are no credit card charges or additional paperwork. Processing sales with other forms of payment differs only in the payment method. Follow these steps when accepting payment using a personal check:

1. Get a driver's license number and write it on the check.
2. Compare the license photo ID to the customer's appearance.
3. Use a check verification process.
4. Apply store endorsement to the check before placing it in the cash drawer.
5. Post the check number.

Credit cards and debit card concerns include the following:

- Make sure the credit/debit card belongs to the customer.
- Check the information on the credit/debit card against the customer's photo ID.

E-COMMERCE E-commerce refers to the process of buying or selling products or services over the Internet. E-commerce sales involve the following:

1. The online order is received.
2. The order is processed using the store's back-office system.
3. The customer is notified that the order has been received.
4. A request for fulfillment is sent to the warehouse.
5. The order is picked from stock at the warehouse.
6. The order is packed at the warehouse.
7. The order is shipped from the warehouse.
8. A shipping notification is sent to the customer.
9. The customer receives the order.

REFUNDS AND CREDIT INVOICING Parts specialists need to be familiar with the store's **charge policy** to provide the best customer service. If a sale needs to be voided or credited, parts specialists should know the steps necessary to complete this action. The procedure for refunds should be specific to the business and to the specific processor.

HOUSEKEEPING SKILLS **Housekeeping** relates to keeping all areas of the business clean and orderly; everyone in a parts store must have housekeeping skills. Lost sales can result from a disorderly and sloppy appearance. Countertops, shelves, and displays should all be neat and clean. Good housekeeping leads to a safe, clean, and productive environment. The following are some general housekeeping guidelines:

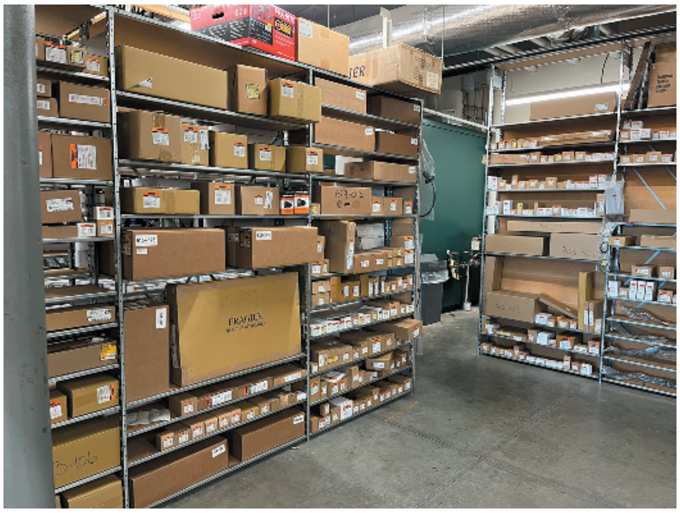


FIGURE 134–2 Even areas customers do not see should be clear of clutter to provide a path for employees to walk.

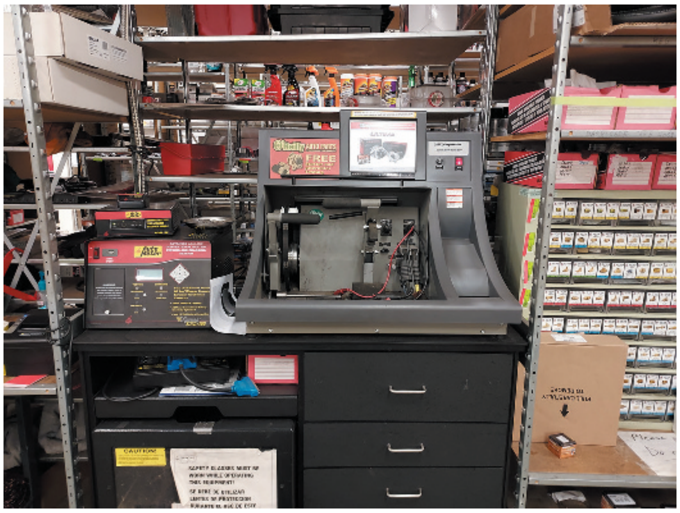

FIGURE 134–3 Most parts stores offer starter and alternator testing as part of their customer service policy.

- Keep aisles and walkways clear of tools, equipment, and other items. ● **SEE FIGURE 134–2.**
- Make sure that garbage containers are conveniently located and emptied regularly.
- Keep all lights in working order.

ADDRESS CUSTOMER CONCERNS Parts specialists should always sell the right parts to customers. This may involve educating the customer about the parts being bought and the importance of related items or tasks to be performed in combination with the parts installation. If a customer comes in for a starter while carrying a pair of jumper cables, the wise parts specialist will ask: "What is the problem that makes you think you need a starter motor?" The specialist may also mention that the battery or wiring could be the problem. ● **SEE FIGURE 134–3.**

PROPER SAFETY PRACTICES All parts specialists must maintain a safe environment to avoid personal injury or damage to the merchandise or customers. Safety includes the following:

- Learning about all safety precautions.
- Applying this safety precaution knowledge while working by developing safe working habits.
- Receiving training on how to lift heavy objects. Some heavy components should be moved with handling equipment like a forklift.

Following safety practices results in protecting employees and customers from harm.

POTENTIAL SECURITY RISKS Expensive items should be displayed behind the counter in locked cases. Parts specialists should give thought as to what is displayed near entrances and exits to avoid theft. It is best to use a video surveillance system and keep the areas around entrances clear.

FREQUENTLY ASKED QUESTION

What Is a Customer Satisfaction Survey?

A **customer satisfaction survey** is a study of customers' perceived satisfaction with a product or service. A completed survey provides answers for a list of questions that a company has concerning its products or services. Identifying unhappy customers is as important as identifying extremely happy ones (i.e., potential advocates). Parts stores can use a number of survey websites to help determine their level of customer satisfaction.

CUSTOMER RELATIONS AND SALES SKILLS

CUSTOMER SATISFACTION **Customer satisfaction** is defined as the customer's overall feeling of satisfaction with an interaction with the store. Customer satisfaction recognizes the difference between customer *expectations* and customer *perceptions*. Satisfaction may develop quickly or may be refined over time.

APPEARANCE All aspects of the parts specialist's appearance, including clothing, personal hygiene, and outward demeanor, create a first impression with customers. First impressions affect the level of trust achieved. It is harder to convey a message effectively if the customer is distracted by some aspect of the parts specialist's appearance. Thus the parts specialist should always have a professional appearance.

ACKNOWLEDGING AND GREETING CUSTOMERS From the moment customers walk through the door until they leave, employees should welcome and acknowledge them in a friendly manner. Parts specialists should not hold personal conversations with one another when a customer is at the counter. The first step toward making customers feel noticed is to make eye contact with them and say "Good morning/afternoon" and "I'll be with you in a few minutes." Customers should be waited on in the same order in which they came into the store.

HANDLING DIFFICULT CUSTOMERS When confronted with a difficult customer, consider doing the following:

- Listen. It is important to allow the customer to explain the problem or concern even if it involves a long and drawn-out story.
- Do not get angry. Remember that the customer is upset at the situation, not at the parts specialist.
- Ask questions. Seek clarification of the problem and determine the variables involved.
- Show empathy. Attempt to understand what the customer is experiencing.
- Determine the most appropriate solution to the problem. Use creativity and follow company policies to create a positive outcome for both the customer and the business.
- Follow up. Restate what has been decided and how the situation is being resolved. Ask the customer whether they have any further questions.
- End on a positive note. Thank the customer for their understanding. Bid them farewell in an enthusiastic manner so they remember the professional manner used to resolve their problem. Customers are more likely to remember the end of an interaction than the beginning.

UNDERSTANDING WARRANTIES AND RETURN POLICIES Parts specialists should help customers understand the terms of sale, such as cash or credit sales. **Warranties** are almost always offered by the part manufacturer. Some warranties are for 30 to 90 days or for one year after purchase. An extended warranty may apply to parts such as batteries or tires. A lifetime warranty may be offered on products that can be returned with proof of purchase at any time after the sale for a replacement. **Return policies** vary by store. For example, for some companies, electrical and electronic parts are sometimes not returnable for reimbursement.

ANSWERING THE TELEPHONE The telephone is a powerful tool for sales, information gathering, and relationship building. A telephone call is often the first point of contact a customer has with the store. Creating a good first impression helps establish positive feelings about the store. Some useful telephone tips include the following:

1. Answer calls promptly and be prepared to handle them. Answer at the second ring if possible. When the telephone rings longer, callers get the feeling that no one is available and that their call is an intrusion.
2. Have paper and pens handy to take notes. Use a computer-based customer system for reference. Get the caller's name and number as soon as possible, and summarize the conversation briefly at the end—especially mentioning any commitments that need to be followed up on.
3. The best way to answer a business call is for the parts specialist to simply state their name or department and ask, "How may I help you?"
4. Use proper titles for people when communicating. If in doubt about whether to use a customer's first name, call the person by the more formal Mr. or Ms. If they prefer that their first name be used, they will say so. It is better to be a little too formal than overly familiar.
5. "Thank you" is the most powerful phrase in human relations. Express appreciation regularly. Some companies use it as a greeting: "Thank you for calling Jones Buick." A "Thanks for calling" at the end of a conversation is also a strong customer satisfaction booster.
6. Keep the conversation businesslike. Nothing turns off a customer or caller like forgetting their name. If this happens, simply say, "I'm sorry, I didn't get your name, sir/ma'am. Would you please repeat it?"
7. Speak clearly and distinctly. Avoid using speaker phone.
8. Do not allow "dead air." When dead air occurs, callers have no idea what is going on and are often annoyed if the silence persists.
9. Take messages cheerfully and accurately. Get customers' full names and correct spelling by asking callers to spell their names. Also ensure their correct telephone number is recorded.
10. Try to picture customers on the phone. Physically smiling somehow travels through the telephone line via voice tones.

FIGURE 134–4 Smiling while talking on the telephone conveys a positive attitude to customers.

TECH TIP

How to Handle Customers When Times Are Busy

Sometimes the phone will ring while the parts specialist is waiting on a customer. When no one else is available to answer the phone, the parts specialist should ask the customer to stand by and then answer the phone, requesting the caller to hold. The parts specialist should never pick up the phone and press the hold button without talking to the caller. If it appears that the call will take some time, the parts specialist should try to explain to the caller that they are with another customer at the moment. Return the call as soon as possible or tell the caller to call back in a few minutes.

Keep a mirror by the telephone to remember to smile. It really does come through to callers. ● **SEE FIGURE 134–4**.

11. When the phone rings, the first thing all associates should think is, "There's an opportunity on the phone—here we go!" It's time to smile, breathe, and project energy and enthusiasm with a heartfelt greeting.
12. Make sure the conversation is finished before hanging up. If the parts specialist initiated the call, the parts specialist should take responsibility for ending it. Use conclusion words such as, "Thank you for the help."
13. When leaving a message on a customer's voicemail, be sure to state the following:
    - Your name
    - The time and day of the call
    - A brief explanation of why the call was made
    - A phone number
    - When the customer can reach the parts specialist
14. Don't let a telephone call interrupt an important live conversation. One concern of many customers is having their discussion with a parts specialist interrupted by a phone call. If a phone call must be answered, always indicate this to the customer in a polite way. Ask the caller if they are able to hold. If they are not, they should be called back promptly.

HANDLING DIFFICULT PEOPLE ON THE PHONE

Here are some tips for handling upset callers:

STEP 1: Try to understand why they are upset. Three common causes of anger or frustration arise from people feeling that

- They are not valued or important
- They are helpless
- "It" just isn't fair

STEP 2: Try diffusing their anger or frustration with statements or questions such as the following:

- "Help me to understand." This encourages customers to explain why they are upset. Do not try to defend or argue with their perceptions—they know what they feel, even if it does not make a lot of sense.
- Express empathy by saying, "I can understand feeling that way." Do not say "I know exactly what you mean," because that may not be true. Instead, convey an idea of what they might be feeling.
- Ask, "What would be a good solution from your point of view?" This begins to shift the conversation away from the venting of emotion toward solution seeking.

Always ask, "Is this a convenient time to talk?" If it really is not a good time, let the caller know and arrange another time to talk that would be more convenient. Then arrange a callback.

SELLING RELATED ITEMS

If a customer comes into the store to purchase a product, the parts specialist should suggest buying related items. Selling related parts when a customer buys a particular part can boost sales. For example, when selling brake pads, suggest Brake Clean to prevent brake dust from going airborne, brake pad silencing gel or spray, and caliper slide lube. ● **SEE FIGURE 134–5**.

HANDLING SALES OBJECTIONS

Sales objections may occur when a customer has a problem with the price or item. Wise parts specialists should say: "Why do you feel that way?" This approach politely tries to find out the customer's real objection. By explaining the features and benefits of the product, the customer may understand the price better. Parts specialists should understand different customer types and determine their needs. Customers may need to be convinced that a repair can and should be performed sooner rather than later if safety is involved.

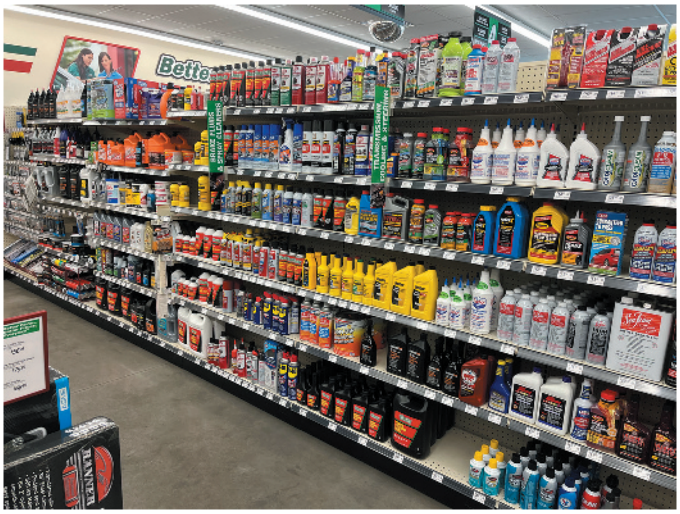

FIGURE 134–5 Products that are related are often arranged together so customers see related items while shopping.

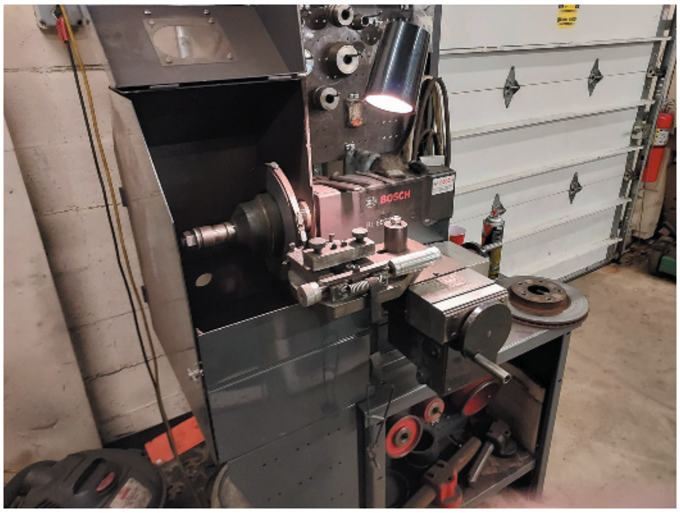

FIGURE 134–7 Many parts stores are also equipped to handle brake drum and rotor machining.

FREQUENTLY ASKED QUESTION

What Is Meant by "Upselling"?

Upselling refers to the attempt to increase sales above and beyond what the customer first wanted. For example, parts specialists could suggest that brake cleaner would also be helpful when they sell brake pads to a retail customer. Other examples of upselling include

- Recommending a funnel and gloves to a customer purchasing engine oil and an oil filter.
- Recommending a new accessory drive belt to a customer purchasing an alternator.
- Recommending a new battery or battery cable to a customer purchasing a new starter.
- Recommending microfiber cloths to a customer purchasing wax or polish.

Additional sales help the store be more profitable by increasing the total revenue of the store.

PROMOTING SALES AND STORE SERVICES Parts specialists should always promote sales and store services. For example, if a customer asks for brake pads, let the customer know that the store has a machine shop service that can machine the rotors. If a customer is purchasing tires, suggest mounting, balancing, and wheel alignment service. If the store does not do this, recommend a reputable shop that can. ● **SEE FIGURES 134–6 AND 134–7.**

CLOSING THE SALE Closing the sale means getting a commitment from the customer. Parts specialists need to overcome objections customers may have to purchasing at that time. For example, to help close a parts sale, a parts specialist could tell the customer:

- "This part has very good reliability."
- "This special price will end soon."
- "This is the best price."
- "This product has a longer warranty."

PRODUCT APPLICATION INFORMATION AND VEHICLE IDENTIFICATION

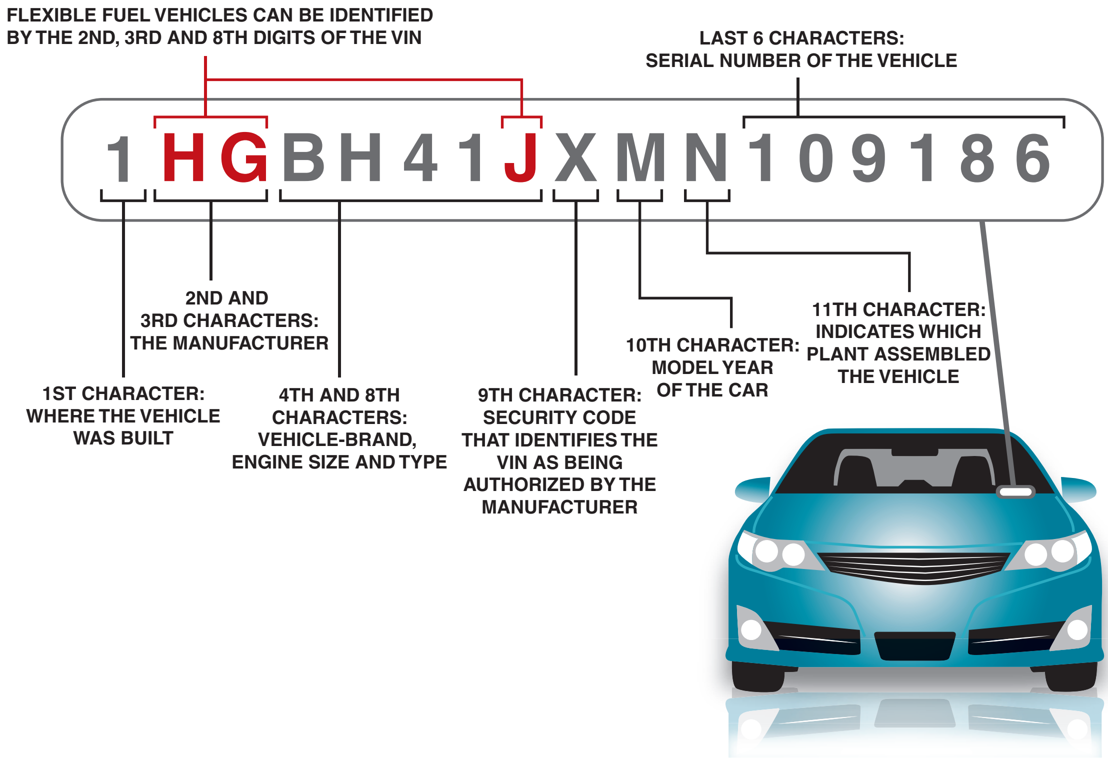
Proper selling techniques help customers leave the store with the part they need. To get the correct part, parts specialists must obtain the right vehicle information, including the following:

- year
- make
- model
- engine
- drive line

Sometimes, additional information such as the wheel or tire size, wheelbase, presence or absence of air conditioning, or the 17-character **vehicle identification number (VIN)** may be needed from customers when researching their parts needs. Having the right information will ensure the customer is sold the correct parts. ● **SEE FIGURE 134–8.**

Although every vehicle manufacturer assigns various letters or numbers within these 17 characters, there are some constants, including

- The first number or letter designates the country of origin.
- The model of the vehicle is commonly the fourth and/or fifth character.
- The eighth character is often the engine code.
- The tenth character represents the model year (MY) on all vehicles.



FLEXIBLE FUEL VEHICLES CAN BE IDENTIFIED BY THE 2ND, 3RD AND 8TH DIGITS OF THE VIN
LAST 6 CHARACTERS: SERIAL NUMBER OF THE VEHICLE
1 H G B H 4 1 J X M N 1 0 9 1 8 6
2ND AND 3RD CHARACTERS: THE MANUFACTURER
11TH CHARACTER: INDICATES WHICH PLANT ASSEMBLED THE VEHICLE
10TH CHARACTER: MODEL YEAR OF THE CAR
1ST CHARACTER: WHERE THE VEHICLE WAS BUILT
4TH AND 8TH CHARACTERS: VEHICLE-BRAND, ENGINE SIZE AND TYPE
9TH CHARACTER: SECURITY CODE THAT IDENTIFIES THE VIN AS BEING AUTHORIZED BY THE MANUFACTURER

FIGURE 134–8 Explanation of the VIN code located on the dash visible through the windshield and also on the driver's side door pillar.

Parts specialists should also know how to find the following additional information about the vehicle:

- Vehicle build date
- Vehicle-specific options
- Body style and chassis type
- Paint color codes

VEHICLE SYSTEMS KNOWLEDGE

Parts specialists should have a basic knowledge of vehicle systems and components. Review the chapters in ● **CHART 134–1** for more information.

CATALOG/INFORMATION SYSTEM SKILLS

CATALOGING SYSTEMS Parts specialists must be familiar with digital and/or online cataloging systems. **Subscription-based electronic information retrieval systems** serve both the OEM and the aftermarket. Program jobbers like NAPA, CARQUEST, AutoZone, and Advance Auto contract for the use of electronic parts systems to make information retrieval faster, easier, and up-to-date.

USING THE PROPER RESOURCE TO IDENTIFY PARTS To obtain the correct replacement part, often the owner or parts specialist must supply additional, specific information. For example, when parts are ordered for a differential assembly, the exact axle specification must be determined. OEMs use differentials from more than one axle manufacturer. Each OEM has its own individual ratios, parts, service procedures, and specifications.

Chapters containing information regarding vehicle systems information and parts identification.

INTERPRETING ADDITIONAL INFORMATION Parts specialists must refer to an online catalog to reference additional information, determine parts exceptions, or find alternative parts. A **footnote** is used to provide additional information for multiple applications. The footnotes themselves are important and should be referenced systematically in order to define parts.

Parts bulletins inform the parts store personnel about technical changes to a part. New vehicle information is found on parts bulletins. A **technical service bulletin (TSB)** alerts parts specialists of technical information regarding the part and any new model information. A **supersession bulletin** alerts parts specialists of a superseded part.

CONSULTING ADDITIONAL REFERENCE MATERIAL

Besides parts catalogs, other **reference materials** provide information to parts specialists. These include

- New item bulletins
- Product information bulletins, which contain specific information about a product, such as a defect or a unique method of installation
- Correction bulletins, which refer to catalog errors due to keystroke errors or incorrect parts numbers
- Parts specification guides, which help determine correct parts based on their dimensions, and electrical connections
- Illustrated part guides, which help parts specialists identify the correct replacement part if the original part number is not known or the old part is not available for inspection
- Cross-reference lists and supersession lists, which offer replacement part numbers if earlier issued parts are no longer available

IDENTIFYING TERMINOLOGY AND ABBREVIATIONS

The Society of Automotive Engineers (SAE) releases practices for nomenclature (parts names) in the industry. Parts specialists must be familiar with these and the OEM counterpart names if used. OEMs include aids for using these information-retrieval systems. These include an abbreviation list, which can be helpful since abbreviations can often have more than one meaning. For example:

- OD can mean overdrive or outside diameter.
- AC can mean alternating current or air conditioning.

INVENTORY MANAGEMENT

LOST SALES REPORTING

The main benefit of a **lost sales report** is to spot trends in the parts business. This type of report shows new part numbers that the store does not stock along with older part numbers that are increasingly in demand. Some part numbers have an instant demand, such as those found in some newer vehicles. Other parts grow in demand. The store owner or buyer must investigate not only part numbers that are selling, but also those that they do not stock.

VERIFYING INCOMING AND OUTGOING MERCHANDISE

A shipment order must be carefully picked, packaged, and documented. The packing list or slip is included with each shipment. This slip contains a detailed description of all parts included in the shipment. A separate packing list can be placed in each part of a shipment, but often a single all-inclusive list is packaged with or secured to the first part of a multiple-part shipment.

KNOWING REASONS FOR PHYSICAL INVENTORY

Physical inventory should be performed once a year, when all the stock is counted on the shelves and checked to determine what is actually in the store versus what the computer system shows. This helps keep the computer inventory current and can help provide customers with faster and more accurate parts service. Some parts stores perform inventory on one product line per month as part of a continuous process; others do a complete inventory every year. A physical inventory may show whether parts are missing from the store and whether some part numbers have been incorrectly invoiced.

IDENTIFYING AND REPORTING INVENTORY DISCREPANCIES

After a physical inventory has been completed, any discrepancies must be recorded and logged into the computer system. The cause of the discrepancy needs to be identified (e.g., wrong stock numbers, stolen products, transfers to other stores, incorrect part numbers, or quantities of parts picked off the shelf). Parts specialists must attempt to eliminate discrepancies by using an **inventory discrepancy form**. Such forms should be kept for future reference. When a discrepancy is discovered in the inventory, the records need to be changed.

STOCK ROTATION

Stock rotation means selling older stock ahead of newer stock. This can be done by placing older parts or chemicals in front on shelves where they are visible and where customers can easily select them. This **FIFO (first-in-first-out) stock rotation** prevents older stock from getting an aged appearance. ● **SEE FIGURE 134–9**.

OUTSIDE PURCHASES

An **outside purchase** is a non-stocking part that has been ordered from an outside supplier. A part that repeatedly appears on a lost sales report and needs to be special ordered or that appears on outside purchase reports should be considered as a candidate for normal stock.

CORE HANDLING

A **core charge** is a charge that is added when the customer buys a remanufactured component like a starter or alternator. The core charge is refunded to the customer when the old core is returned. To make sure that customers return the core, the store should charge the core charge to the customer upfront when the rebuilt component is purchased.

PRODUCT PACKAGING

Parts specialists need to be knowledgeable of how various products are packaged to bill and sell them. The term *EACH* is for a single item. A *CARTON* or *CASE* is several parts that are packaged together and sold as a unit. The term *PAIR*

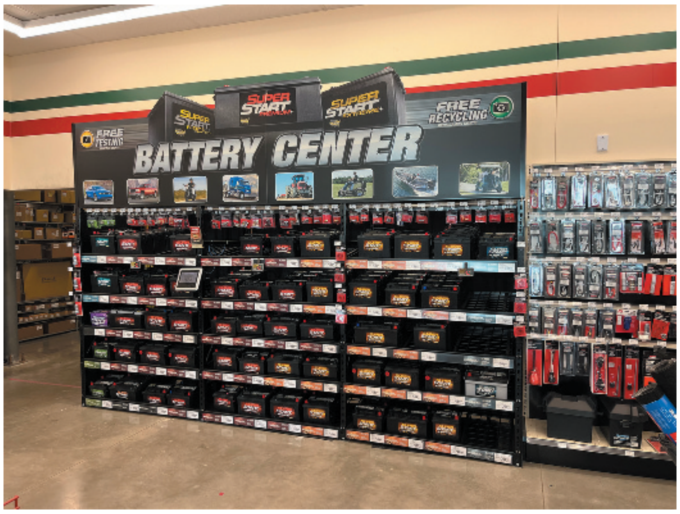

FIGURE 134–9 Batteries are one example of a product that shops need to keep up to date because batteries lose capacity over time. Most batteries have a date sticker, which can help parts specialists determine when batteries have been on the shelf unsold for a period of time.

is two of something. *SET* is two or more compatible items. A *KIT* is a package of parts used to rebuild a component. For example:

- Brake pads are sold as one unit in one box.
- Shocks are sold as individual units.
- Engine oil is shipped by the case but can be sold by the quart.

RETURNS AND EXCHANGE PARTS Freight charges may be added to emergency-order parts to cover the cost of special transportation to the store. Some parts have a restocking fee that is charged to the customer when a product is returned for a refund. Broken kits may not be acceptable for refund, or if a kit is accepted for refund, it must be checked to ensure the kit is resalable, with no missing or damaged parts. Exchange parts must be inspected for resalable condition.

CASE STUDY

The Case of the Overwhelmed Parts Store Manager

The manager of a locally owned and operated automotive parts store felt overwhelmed every day. It seemed as if there was always more to do. Plus, the store was hard to keep looking clean because many of the part cores were dirty and often leaked fluids. The parts manager saw an advertisement for an automotive expo nearby that offered both technical as well as management training sessions. The parts store manager signed up to attend the management classes. During one management session, the parts manager learned one important lesson:

> *"Nothing should be on the floor that does not have to be on the floor."*

Everything should be placed off the floor and on shelves or in cabinets, and only those items that are heavy, such as a brake lathe, should be on the floor. By keeping almost everything else off the floor, cleaning is made easier and the store appears neat and clean for a longer period of time.

After returning from the expo, the parts manager spent about a week making a place for everything and putting everything in its place. Now instead of placing cores on the floor or on the steps leading to the upper level of shelving, the parts manager purchased plastic bins and placed the cores in the plastic bins on a shelf. Larger cores, such as rack and pinion assemblies, were kept on a shelf and off the floor. After about a week, the parts manager finally had a handle on the store. By keeping almost everything off the floor, cleaning was a lot easier. Customers even noticed that the store always looked clean and neat.

Summary:

Complaint—The parts store always seemed to be messy and was hard to keep clean, making the parts manager feel overwhelmed.

Cause—Almost everything, especially cores, were on the floor of the parts store, making it difficult to clean and keep clean.

Correction—The parts store manager learned to keep the store looking clean by keeping almost everything off the floor.

INVENTORY TURNOVER Inventory turnover is crucial to maintain profitability. When inventory sits for too long, it can eventually become wasted inventory that is no longer salable, which hurts profitability. When ordering and stocking inventory, the product turnover and sale likelihood must be considered.

MERCHANDISING

POINT-OF-PURCHASE The best place for a display is in an open area near the front of the store. An attractive display will catch customers' eyes when they enter. A display should be large and appealing to the customer. This can be accomplished by building the display out of the product being sold with the intent of the customer picking the item from the display. Many times, the OEM of a product will send a display kit, which is assembled in the store. Often included with such kits are shelves, banners, signs, and handouts. Displays are also often built near the cash register as a **point of purchase (POP)** display, so that customers notice the product when they pay. ● **SEE FIGURE 134–10**.

PRICE DISPLAY PRODUCTS The practice of display pricing is to feature an item that is specially priced as a display in an open part of the store or department. Along with the display is a noticeable sign that calls out the special pricing. The product that is specially priced may remain in its assigned shelf position, but this additional display lets customers know the part is on sale. A customer is more likely to notice a display with a posted price than notice a specially priced item on the shelf in its normal position. This type of display and pricing is also used to introduce new items. A vendor may also choose to put up a display when certain items are overstocked. This helps promote the item and possibly leads to increased sales.

IDENTIFYING SEASONAL, IMPULSE, AND RELATED ITEMS A **seasonal item** is something that is stocked only at certain times of the year or throughout the entire year but not in large quantities. For example, dry gas is an alcohol-based product used to remove moisture from fuel lines and tanks on gasoline-fueled vehicles in the winter months. Batteries fail more often in the winter, so more of them should be kept in stock during the winter months. An **impulse item** is a product that the customer

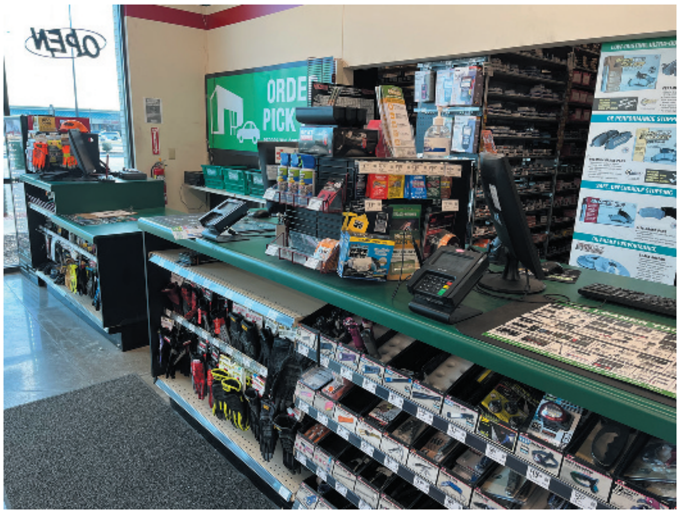

FIGURE 134–10 The point of sale is often another place where a potential sale can be made by displaying small and popular items near where customers pay.

TECH TIP

End Caps

An **end cap** is a rack or counter at the end of a store aisle used to display promotional or sale items. Studies repeatedly show that end caps sell better than in-aisle displays of the same product(s). Frequent rotation of products displayed on end caps rather than the regular shelves often makes economic sense because they grab customers' attention. ● **SEE FIGURE 134–11.**

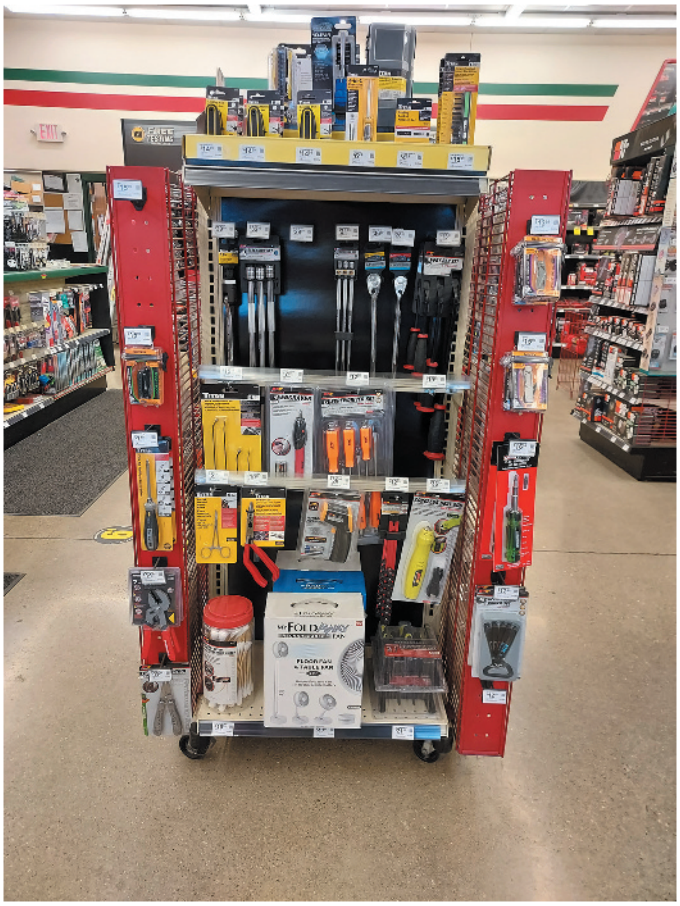

FIGURE 134–11 End caps are a highly visible location where select products are showcased.

FREQUENTLY ASKED QUESTION

What Is a Loss Leader?

A **loss leader** is a product that is sold for less than the usual or expected price in an effort to entice customers to visit the parts store to purchase the item. Once customers are in the store, they often purchase other items or services that are not highly discounted. It is these purchases of the higher-priced items that make selling a loss leader at a discount worth it to the store.

buys to fill a want rather than a need. Some examples of impulse items include

- speakers
- phone adapters and cables
- chrome accessories
- interior items like extra cup holders or seat covers

CHAPTER QUIZ

1. A customer comes into the store while a parts specialist is on the telephone with another customer. Which of the following should the parts specialist do?
   - **a.** Finish with the telephone customer first.
   - **b.** Put the telephone customer on hold and wait on the walk-in customer.
   - **c.** Acknowledge the walk-in customer and finish with the telephone customer.
   - **d.** Finish with the telephone customer before greeting the walk-in customer.
2. To obtain the correct part, parts specialists should know how to locate what vehicle information?
   - **a.** Vehicle options
   - **b.** VIN
   - **c.** Build date
   - **d.** All of the above
3. Parts specialists should have a basic knowledge of which of the following?
   - **a.** Computer programming
   - **b.** Excel spreadsheets
   - **c.** Vehicle systems
   - **d.** Store shelving systems
4. Which of the following plays a role in creating a positive first impression for customers?
   - **a.** Clothing
   - **b.** Personal hygiene
   - **c.** Outward demeanor
   - **d.** All of the above
5. What is the purpose of an end cap?
   - **a.** To hide the end of the shelf
   - **b.** To showcase merchandise
   - **c.** To store unneeded parts
   - **d.** Any of the above
6. Parts catalogs are normally available in ___________ format.
   - **a.** digital
   - **b.** online
   - **c.** paper
   - **d.** Either a or b
7. Which of the following is NOT a topic of the parts specialist P2 ASE certification test?
   - **a.** Customer relations
   - **b.** Tire repair
   - **c.** Vehicle identification
   - **d.** Merchandising
8. Parts Specialist A says that there is no reason to use a lost sales report. Parts Specialist B says that many stores use a lost sales report to analyze parts that do not sell very well. Which specialist is correct?
   - **a.** Parts Specialist A only
   - **b.** Parts Specialist B only
   - **c.** Both Specialists A and B
   - **d.** Neither Specialist A nor B
9. Which of the following parts orders would be considered a special order?
   - **a.** An order placed once a week
   - **b.** An order for a part the store does not normally stock
   - **c.** An order for new customers only
   - **d.** An order intended only for store employees
10. To provide the most effective product sales promotion, where should the product display be placed?
    - **a.** Less than 3 feet high
    - **b.** Near the stocking area
    - **c.** Above eye level
    - **d.** Where it can be seen

SERVICE CONSULTANT (C1)

LEARNING OBJECTIVES:

After studying this chapter, the reader should be able to:

- Discuss the communication and customer relations skills required of a service consultant.
- Discuss how to project a professional image as a service consultant.
- Describe how to greet customers.
- Discuss how to write work orders.
- Describe how to handle customer complaints.
- Explain effective service sales skills.
- Discuss automotive product knowledge needed for service consultants.

KEY TERMS:

Appointment 1730 • Appointment log 1730 • Communication 1722 • Customer satisfaction 1727 • Estimate 1729 • Ethics 1728 • Eye contact 1725 • Five basic needs 1728 • Listening 1722 • Nonverbal communications 1723 • Repair order log 1730 • Service history 1727 • Service pricing menu 1729 • Trust 1730 • Vehicle safety certification label 1731 • Voice inflection 1722 • Work order (repair order) 1725

COMMUNICATION AND CUSTOMER RELATIONS

Communication refers to the process of sending and receiving messages with other people. If the outcome of the communication is not what we intended, the communication was not effective. Communication is a vital skill for service consultants. Two basic types of communication include listening and talking.

LISTENING TO CUSTOMERS

Listening to customers is more difficult than it may seem. A person speaks at the rate of 150 to 200 words per minute, yet we talk privately to ourselves at the rate of 1,300 words per minute. The problem is that our brain may start talking to us before the other person has finished speaking. Good listening requires that we focus our attention on those speaking to us. The following are tips for being a good listener:

- Be attentive; concentrate and focus on the speaker.
- Show interest about what other people think and feel.
- Show understanding and demonstrate empathy.
- Balance input; do not dominate conversations.
- Do not finish the sentence for the other speaker or interrupt.
- Paraphrase what was said to ensure accurate understanding.
- Share positive comments.
- Make eye contact when appropriate.
- Control body language; try not to show impatience or disapproval.

When service consultants listen to customers it shows they care about and respect their questions and concerns. However, it takes practice and dedication to improve listening skills. Listening is a skill that must continuously be developed, but by focusing on customers and on what they are saying, misunderstandings are less likely.

TALKING TO CUSTOMERS

Voice inflection refers to the variation in pitch, timing, or loudness of the voice. Problems with voice inflection can be amplified by the telephone. To improve voice inflection, try the following:

- Record yourself.
- Ask friends for their honest assistance.
- Make a conscious effort to improve.
- Keep listening to yourself. It is easy to slip back into old habits. Excellent voice inflection takes practice!

FREQUENTLY ASKED QUESTION

What Is the Circle of Communication?

The *circle of communication* involves two individuals transmitting and receiving messages in an easy-to-understand way. ● **SEE FIGURE 135–1.**

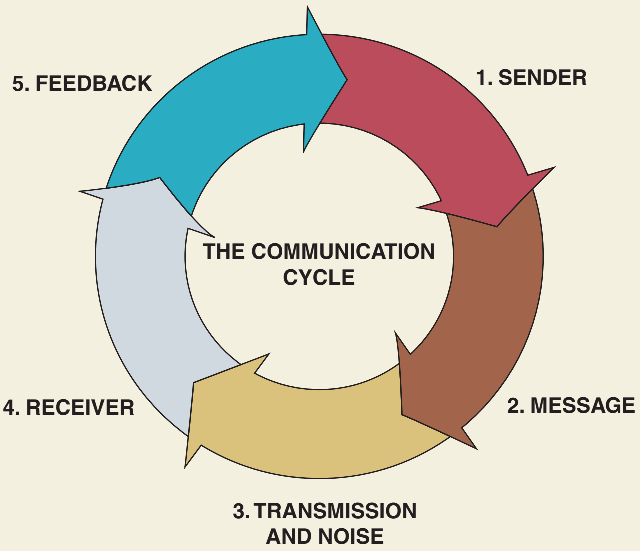

FIGURE 135–1 The circle of communication includes the sender transmitting a message and the receiver understanding it, as well as responding and providing feedback.

NONVERBAL COMMUNICATION **Nonverbal communication** includes such things as:

- Eye contact/lack of focus
- Gestures
- Body movements
- Mannerisms
- Posture

Having one's arms crossed or looking at other things rather than paying attention to what is being discussed can result in communication problems. Body language can override poor verbal communication, but there are generally no words that can override poor body language.

A customer's nonverbal communication may indicate that they are not interested in or do not believe or understand what is being said. If this type of nonverbal communication occurs, consider doing the following:

- Ask questions, which would require the customer to pay attention and express their lack of understanding, plus it demonstrates interest in what they think.
- Give the customer options rather than just ask them what they want, such as saying, "Would you prefer to have this work done all at the same time or spread out over several weeks?"

TELEPHONE COMMUNICATION A telephone call is often the first point of contact a customer has with the shop. A phone call therefore creates a first impression in customers' minds about the shop, its efficiency, and employees' communication skills, friendliness, and expertise. However, on a phone call, people interact without the visual feedback that helps us assign meaning to spoken messages. The following are some tips for using the telephone professionally:

1. Answer promptly. An answer after two rings or less conveys efficiency and a willingness to serve. The best way for service consultants to answer a business call is to simply state their name or department and ask, "How may I help you?"
2. Have paper and pens handy to take notes. Use a computer-based customer system for reference. Get the caller's name and number as soon as possible, and summarize the conversation briefly at the end—especially mentioning any commitments that need to be followed up on. ● **SEE FIGURE 135–2.**
3. Use proper titles for people when communicating. If in doubt about whether to use a customer's first name, call the person by the more formal Mr. or Ms. If they prefer that their first name is used, they will say so. It is better to be a little too formal than overly familiar.
4. Express appreciation regularly. Some companies use it as a greeting: "Thank you for calling Jones Buick." A "Thanks for calling" at the end of a conversation is also a strong customer satisfaction booster. It reassures customers that their calls are not an intrusion.
5. Keep the conversation businesslike. Nothing turns off a customer or caller like forgetting their name. If this happens, simply say, "I'm sorry, I didn't get your name, sir/ma'am. Would you please repeat it?"
6. Some service consultants find it helpful to list "Words to Use" and "Words to Avoid" on a card so that it is available for easy reference. ● **SEE CHART 135–1.**
7. Speak clearly and distinctly and avoid using speaker phone.
8. Do not allow "dead air." When dead air occurs, callers have no idea what is going on and are often annoyed if the silence persists.
9. Take messages cheerfully and accurately. Get customers' full names and correct spelling. If the name isn't clear, ask the caller to spell it. Also ensure their correct telephone number is recorded.
10. Smile. Smiling while speaking on the phone creates a friendly tone.

FIGURE 135–2 When answering the phone, be sure to have paper and pen or pencil handy.

Would you like	We'll try
Opportunity	Haven't had time
Challenge	I don't know
Regret	Hang on for a second

CHART 135–1

A list of suggested words to use compared to a list of words to avoid when talking to customers.

11. When the phone rings, the first thing all associates should think is, "There's an opportunity on the phone—here we go!" It is time to smile, breathe, and project energy and enthusiasm with a heartfelt greeting.
12. Make sure the conversation is finished before hanging up. If the service consultant initiated the call, it is their responsibility to end it. Use conclusion words such as, "Thank you for the help." If the service consultant received the call, the caller should be finished before hanging up.
13. Don't let a telephone call interrupt an important live conversation. One concern of many customers is having their discussion with a service consultant interrupted by a phone call. If the service consultant must answer the phone call, ask the caller to hold. If they are not able to hold, call them back promptly.

VOICEMAIL Most shops use some form of voicemail system. Service consultants must be comfortable using such systems. When leaving a voicemail, do the following to increase customer responsiveness:

- Speak clearly and slowly. Service consultants should provide their name, the name of the company, the day and date, and the time.
- State the reason for the call.
- Suggest to the customer what the next step should be. Do they need to call back or wait for more information?
- Leave appropriate contact information and indicate when they can return the call. Provide contact information again, including a phone number.
- Close with a positive farewell.
- Remember that when leaving a voicemail, time may be short, so be as brief and to the point as possible.
- Customers may become frustrated with having to talk to "a machine" when they have a question or problem. When answering complaints about voicemail, do not dismiss the complaint as being unimportant. Ask questions to find out what really went wrong.

TECH TIP

How to Handle an Upset Customer

Here are some tips for handling upset customers:

STEP 1 Try to understand why they are upset. Three common causes of anger or frustration arise from people feeling that:

- They are not valued or important
- They are helpless
- "It" just is not fair

STEP 2 Try diffusing their anger or frustration with statements or questions such as the following:

- "Help me to understand." This encourages customers to explain why they are upset. Do not try to defend or argue with their perceptions—they know what they feel, even if it does not make a lot of sense.
- Express empathy by saying, "I can understand feeling that way." Do not say "I know exactly what you mean," because this may not be true. Instead, convey an idea of what they might be feeling.
- Ask, "What would be a good solution from your point of view?" This begins to shift the conversation away from the venting of emotion toward solution seeking.
- Always ask, "Is this a convenient time to talk?" If it really is not a good time, arrange another time to talk that would be more convenient. Then arrange a callback.

EMAIL/TEXT The ability to communicate with customers is one of the most critical aspects of the service business. Other than direct contact, communication can also be by email or text message. Ask the customer which method they prefer. Many prefer the quick and easy text message, whereas others prefer talking on the phone.

TECH TIP

Email Etiquette

Email etiquette includes the following:

- Double check grammar, spelling, and punctuation
- Avoid long and detailed emails. If an email conversation has exceeded two emails on both sides already, call that person instead.
- Writing in a very friendly manner can come across as too casual, whereas a formal approach can seem too impersonal. Try to write as if addressing a close business contact.
- Reply to emails from others promptly.

CASE STUDY

Telling the Customer It Will Be Ready in an Hour

A customer called to check on the status of their vehicle in the shop for a timing belt replacement. The service consultant checked with the technician and found out that the vehicle would be ready in about 15 minutes. However, the service technician told the service consultant to tell the customer that it would be ready in an hour. This way, the customer would be very happy when it was ready sooner rather than later than promised. Plus, the extra time allowed the technician plenty of time for a test drive to confirm that the repair was successfully completed.

Summary:

Complaint—Customer wanted their vehicle back as soon as possible.
Cause—The repair would be completed in less than 30 minutes, but the technician wanted to be sure so told the service consultant to tell the customer it would be ready in an hour.
Correction—The customer was notified that the repair was done before the hour was up, making the customer very happy.

PROJECTING A PROFESSIONAL IMAGE

Customers notice the personal appearance of service consultants and other team members as well as the appearance of the service center. Appearances often give customers a feeling about the care the service center will give to their vehicle. To convey a professional image, service consultants should be clean and neatly dressed.

When a service consultant projects a "whatever it takes" attitude and shows interest in solving the customer's needs, the customer will be more at ease and be more receptive to the service consultant's recommendations and suggestions. Try to keep the conversation on the subject, ask questions, and listen to let the customer know that the shop cares about them and their vehicle concerns.

NOTE: When all team members are committed to a set of common goals, they can contribute in positive ways to the success of the team. Customer service has a direct impact on the ability of employers to hire employees, provide wages, and offer promotions. In fact, vehicle manufacturers place great importance on the customer satisfaction index rating at their dealerships.

GREETING CUSTOMERS

Follow these steps when greeting customers:

1. Recognize the customer's presence by smiling and cheerfully saying "Hello," even when the service center is very busy. Smiling helps customers relax and feel more comfortable. Remember, they are in an unfamiliar area, one that they may view as being a negative place to visit. If customers are recognized and made to feel comfortable, they are more likely to be patient and wait until they can be helped.
2. Make **eye contact** with customers. In American culture, eye contact conveys sincerity and interest. Avoiding eye contact may suggest a lack of concern or lack of honesty. Customers may perceive that a customer service provider is not interested in what they are saying if they do not periodically make eye contact with them.

NOTE: When dealing with people from other cultures, customer service providers should be aware of cultural differences. In many other cultures, avoiding eye contact is a sign of respect. Be sensitive to others, but use eye contact whenever possible.

3. Service consultants should introduce themselves and state their position at the shop or dealership. Explain what will be happening and the steps that will occur, so the customer is aware of what to expect. For example, the customer needs to know that an accurate estimate may not be possible until a diagnostic procedure has been performed. Let customers know that the shop will contact them after diagnostic procedures have been performed to inform them of the results plus any other additional information.
4. Mention and repeat each step so the customer is assured that the shop is doing exactly what it said would be done. Customers do not like surprises, and while the news is often not good news, keeping customers informed is the best way to avoid misunderstandings.

Customers may be nervous when entering a shop or any other business where they know they may have to spend a great deal of money. Being professional at all times helps customers know that they are in good hands. Ask if they understand what will be done to their vehicle, try to answer all their questions accurately, and avoid using slang terms that may be misunderstood.

WRITING WORK ORDERS

PRIMARY JOB The primary job of a service consultant is to write an effective and accurate **work order** (also called a **repair order**) with repair/service authorization, warranty repair, and customer follow-up. Most dealerships and shops use an electronic repair order system. The process may differ from shop to shop. Some considerations include

- If this is a new client or a new vehicle, missing information may need to be gathered.
- If this is an existing customer (i.e., one that is already in the database), verify the customer information and update it if needed.
- It is very important to capture the customer concern exactly the way the customer states it. For example, if the customer states that their vehicle runs rough, shakes, and sputters when they give it gas from a stop, we know there is an engine running problem. So, the service consultant would enter "Engine Diagnostic" and then the exact customer statement. Determine whether it is a predetermined service such as a brake inspection or tire rotation.

FREQUENTLY ASKED QUESTION

What Is the Purpose of the Pre-Service Inspection?

The service consultant, or another designated person, should perform a quick visual inspection of the vehicle before service work is performed to check for any preexisting body damage or other faults. Any issues found should be brought to the attention of the customer and noted on the work order. If, for example, worn or damaged tires are found, it may be time to recommend that they be replaced during this service visit. The primary reason for the pre-service inspection is to protect the shop from claims of damage that were not caused when the vehicle was under the control of the shop. Many shops have installed cameras to record all views of the vehicle, making a physical inspection unnecessary.

The work order includes:

- Customer details such as name and address
- Vehicle make, model, and year
- Vehicle identification number (VIN)
- Odometer reading
- Date
- Customer concern information
- Cause of the problem(s)
- Correction for the problem(s)
- Hours of labor
- Parts used for the repair

The repair order should always include all of the information pertaining to the customer, vehicle, and cost of repair. The most important part is the VIN. There may be many white Chevrolets, but there is only one vehicle that matches a particular VIN. Repair orders are legal documents that can be used as evidence in the event of a lawsuit. Make sure the information is complete and accurate when filling out a repair order and store it in a safe place or electronically on a secure computer network.

TECH TIP

Listen to the Entire Story

It is important to allow the customer to explain the problem or concern even if it involves a long and drawn-out story. Customers often provide important clues about the problem if the technician or the service advisor is carefully listening. For example, the customer could say that during the previous day before the problem started that the "kid next door slammed the driver's door shut." This one clue could be the root cause of a problem that otherwise would be very difficult to locate. Try to avoid talking or adding to what the customer is saying, no matter how difficult that may be.

DETERMINE THE CUSTOMER'S PRIME CONCERN The service consultant needs to know the customer's main concern for their vehicle on this visit to the shop. To help determined this, ask questions such as:

- What is your main concern?
- Why are you here today?
- What can we do to help?
- When does the problem occur?
- How often does it occur?
- What does it sound like?
- What does it feel like?

Follow with more focused questions that help zero in on the customer concern. These questions could provide additional information such as what type of road the vehicle was being driven on when the problem occurred or whether the vehicle was towing something when the problem happened. The purpose of these additional questions is to gather as much information as possible for the technician so that the root cause can be found and corrected.

CONFIRM WHAT IS EXPECTED When speaking with customers, do not use unnecessary technical jargon. When discussing issues with customers, do the following:

- Speak clearly and concisely.
- Always start with a diagnosis to confirm the fault.
- List the procedures that should be followed according to the online service information to pinpoint the root cause followed by the service procedure.
- State that the repair will be confirmed to assure that the original concern has been addressed.

DOCUMENT THE WORK ORDER The complaint or concern is why the customer brought the vehicle in for service. The service consultant enters the technician's diagnosis on the work order based on the concern. To properly verify the concern:

- Make sure the customer's complaint and the service writer's repair order description are understood before starting work.
- Make sure the correct operation of the system is understood by the customer or the service consultant.
- Check the online service information to verify all aspects of normal system operation.
- Once the repair is complete, provide a short, concise statement about the cause of the concern and the correction or repair necessary to solve the customer's original concern or complaint. ● **SEE FIGURE 135–3.**

THE THREE Cs The three "Cs" are Concern, Cause, and Correction. Remember that each of these sections needs to be written up as concisely and completely as possible. For example:

- **Concern:** The vehicle overheats within about 10 minutes of vehicle operation from a cold start, no matter whether it is hot or cold outside. The coolant is full and protected to −30°F. The engine was started and engine temperature was monitored with a temperature gun. The temperature exceeded the specified 195°F thermostat opening temperature and still did not open at 205°F.

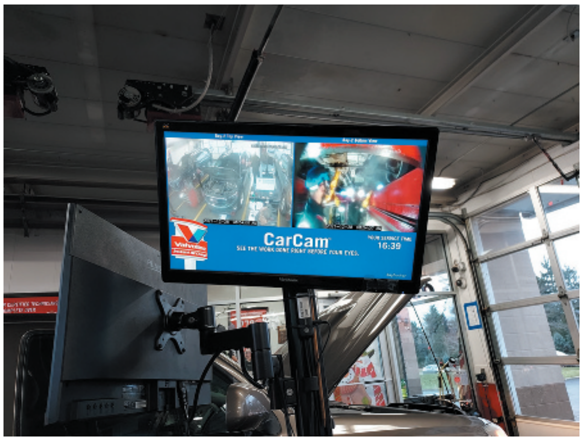

FIGURE 135–3 Some shops are equipped with cameras that show the work being done so customers can view their vehicle while service is being performed. Some shops are equipped with glass between the waiting area and the service area for the same reason.

- **Cause:** Thermostat faulty, not opening at specified temperature. Removed, no external damage noted.
- **Correction:** Replaced the thermostat with a new thermostat. Using a scanning tool, retested and determined that thermostat starts to open at 205°F, which is within specifications.

VEHICLE SERVICE HISTORY Good customer relations require knowing the **service history** of the vehicle. Having service history information available allows the service consultant to track previous service work and to recommend future maintenance. This helps avoid misunderstandings that can occur, such as the request from a customer for an alignment when the actual problem is a vibration that an alignment may not correct. Therefore, be sure that the customer is aware that the shop will try to fix the concern rather than selling parts or service procedures.

SCHEDULED MAINTENANCE NEEDS After reviewing the vehicle service history, the service consultant can suggest any needed maintenance. Multipoint inspections cover many vehicle systems and should be completed at regular intervals. What is inspected and the inspection results should be documented on the work order or on a separate inspection checklist.

CUSTOMER LOUNGE AREA Show the customer a comfortable location where they can wait for the diagnosis or service. Offer the customer a snack or beverage while they wait. The furnishings and cleanliness of the client reception area should be constantly monitored. Often, these areas become cluttered and are not noticed by those working in the area. Try to look at service areas as customers would if they were seeing the area for the first time.

ALTERNATIVE TRANSPORTATION OPTIONS A service consultant may need to offer alternative transportation options to the customer. Car rental sources are often found near repair shops and dealers. Many of these businesses can pick up the customer from the shop. Some shops provide substitute transportation or pay the rental depending on the situation. A free loaner vehicle may be provided under some circumstances involving a warranty repair, liability, or other special consideration. Many shops and dealers provide shuttle service for customers. When shuttling a customer, the following should be adhered to:

- Radios should be off or light music/news stations should be on. Always ask clients what they would like to listen to.
- The climate-control settings should be set to make clients comfortable; again ask clients what they would prefer.
- Ask whether they need to make any special stops while on the way to their destination.

HANDLING CUSTOMER COMPLAINTS

CUSTOMER SATISFACTION **Customer satisfaction** is defined as the customer's overall feeling of satisfaction with an interaction with an automotive service and repair facility. Customer satisfaction recognizes the difference between customer *expectations* and customer *perceptions*. Satisfaction may develop quickly or may be refined over time. Customers have many concerns, and the task of the service consultant is to reduce the stress of vehicle service and to create a pleasant customer experience, while providing current information and helping to solve customers' vehicle repair concerns.

EXAMPLES OF CUSTOMER SERVICE Customer service may involve the following:

1. Calling the customer by name
2. On-time delivery of repaired vehicles
3. Courtesy
4. Enthusiasm
5. Demonstrating care for the customer
6. Excellent follow-up
7. Empathy in handling customer complaints and questions
8. Well-explained repairs
9. Suggesting a less expensive option

CUSTOMER NEEDS Every customer has different needs. While what the customer wants is frequently hard to identify and may

FREQUENTLY ASKED QUESTION

What Is a Customer Satisfaction Survey?

A customer satisfaction survey is a study of customers' perceived satisfaction with a product or service. A completed survey provides answers for a list of questions that the company has concerning its products or services. A survey can also help determine inactive leads. The general purpose of customer satisfaction surveys is to assess how satisfied customers are with different aspects of the product/service. Identifying unhappy customers is as important as identifying extremely happy ones (i.e., potential advocates).

occasionally be unrealistic, all customers have the following **five basic needs**:

- **Service.** Customers expect the service they think is appropriate for the level of purchase they are making. A small, spontaneous purchase may have a smaller service need than a large purchase that has been carefully planned and researched. Exceeding customers' expectations, such as under-promising and over-delivering, is beneficial for businesses as it often results in repeat sales and free word-of-mouth advertising.
- **Price.** People and businesses want to use their financial resources as efficiently as possible. Many products previously considered unique are now considered commodities. This makes the component price even more important to customers.
- **Quality.** Customers want the products they purchase to be durable and functional until they decide to replace them. This requirement of quality mandates that manufacturers and distributors produce products that live up to customers' expectations of durability. Customers are much less likely to question price if they are doing business with a company that has a reputation for producing high-quality products.
- **Action.** Customers need action when a problem or question arises. Customers like to think that they are an important priority and that when a need or question arises, someone will be ready and waiting to help them.
- **Appreciation.** Customers need to know that the shop appreciates their business. Service consultants can convey this appreciation in many ways. Saying "thank you" to the customer through their words and actions is a good starting point. Additionally, letting them know their business is appreciated conveys a positive message.

EXCEEDING CUSTOMERS' EXPECTATIONS To begin attempting to exceed customers' expectations, try the following:

- Become familiar with customers. Get to know who they are and why they do business at the shop. Find out their likes and dislikes.
- Ask customers what their expectations are. Find out what they see as the benefit of doing business at the shop.
- Tell customers what they can expect. Convey to customers a commitment to them.
- Live up to their expectations. Follow through by accomplishing what was promised.
- Always deliver a consistent service. Customers like to know that they will have the same positive experience every time they interact with the shop.

One important key to exceeding customers' expectations is to remember that expectations are always changing.

ETHICS IN CUSTOMER SERVICE Most individuals periodically face ethically challenging situations. **Ethics** are a set of principles that govern the conduct of an individual or group. Sometimes ethical decisions are easy to recognize and are perceived as popular choices of behavior by the people around us. At other times, the spectrum of potential choices falls into gray areas in which the "right" or "wrong" course of action is difficult or nearly impossible to identify.

There are really no shortcuts when it comes to telling the truth and determining an appropriate course of action. Individuals in business must be seen by those around them as honest or they will not succeed for long. The bottom line in decision making is that individuals must face the consequences of their decisions—good or bad. When faced with an ethically challenging situation, ask the following questions:

- Is it legal?
- Is it fair?
- How do I feel about it?
- Would the court of public opinion find my behavior incorrect?
- Am I fearful of what those I trust would say about my actions?

The above questions can be quite revealing when attempting to choose an ethical course of action. This is not to suggest that ethically challenging situations are easily resolved. Analyzing a situation may make the appropriate decision easier to identify.

One final consideration regarding ethical behavior is that it is not always popular to do the right thing. Maintaining individual integrity and an organization's reputation will better enable all involved to choose the most appropriate course of action.

WHY ARE SOME CUSTOMERS DIFFICULT? Customers may be perceived as challenging for reasons such as the following:

- They are visibly upset about something.
- The facility did not repair their vehicle correctly.
- They do not have expertise regarding the specific product or situation.
- They are quiet and noncommunicative.
- They are impatient.
- They have difficulty making decisions.

Every customer should be the most important person at the moment. They come into our shops with past experiences, perceptions, expectations, frustrations, the stresses of daily life, and the desire for us to show that we value them as customers. Customer service providers also bring their own unique backgrounds to an interaction. The difference between customers and customer service providers is that the customer service provider is responsible for building the bridge of communication.

AVOIDING DIFFICULT CUSTOMER INTERACTIONS The following are some tips for avoiding difficult customer interactions:

1. Respect the customer's time. Stay focused on the customer.
2. Do not impose bad or negative mood on anyone else.
3. Recognize regular customers with a smile and try to learn their names. It is not too much for regular customers to expect they would be remembered from one interaction to another. Giving someone a look of recognition is a great place to start. Try for one week to call everyone by name, including coworkers. This may increase the morale in the work area. People usually choose to do business with people who they like.
4. Avoid destructive remarks. Jokes that seem creative and "smart" may seem inappropriate to customers. In the long run, destructive remarks are just that—destructive.
5. Go the extra mile for customers. It is refreshing to do business with someone who offers to do a little something extra and carries through a project to the end.

FREQUENTLY ASKED QUESTION

What Should Service Consultants Do When They Are Wrong?

Customer service providers are only human and may make mistakes. When service consultants believe that they have made a mistake, they should try the following:

- Examine the behavior and words. Try to look at the situation from the customer's point of view.
- Observe the customer's reaction. Is the customer visibly upset? Does the customer seem surprised or hurt by the service consultant's actions?
- Admit the mistake. Regardless of whether it was an error in information or judgment, it is always best to acknowledge it.
- Apologize for the actions or error. Express regret about the problem to the customer, but do not make excuses for why it occurred.
- Find a solution and implement it. The most effective way to undo the improper treatment of a customer is to create an effective solution and to put it into effect as quickly as possible.

HANDLING DIFFICULT CUSTOMERS When confronted with a difficult customer, consider the following:

1. **Listen.** Allow customers to express their concerns or to share their side of the story.
2. **Try not to take it personally.** Remember that the customer is upset at the situation, not at the service consultant personally.
3. **Ask questions.** Seek clarification of the problem. Determine the variables involved.
4. **Show empathy.** Attempt to understand what the customer is experiencing.
5. **Solve the problem.** Determine the most appropriate solution to the situation. Use creativity and follow company policies while seeking to create a positive outcome for both the customer and the business.
6. **Follow up.** Restate what has been decided and how the situation is being resolved. Ask the customer whether they have any further questions.
7. **End on a positive note.** Thank the customer for their understanding. Bid them farewell in an enthusiastic manner so that they remember the professional manner used to resolve their problem. Customers are more likely to remember the end of an interaction than the beginning.

SALES SKILLS

ESTIMATES The service consultant is the first person to discuss concerns customers have about their vehicle and is ultimately responsible for writing up the repair order and providing the initial estimate of repair. An **estimate** is the suggested service cost to the customer, which is determined by the service consultant. It is the estimate of what the expected service costs will be. Labor time guides list how much time will be involved in performing a standard or warranty-related service or repair. Flat-rate servicing costs are usually derived from a labor time guide. The writeup is the same as a repair order. The service estimate can be part of the repair order or a separate document.

SERVICE PRICING A **service pricing menu** provides a quick reference for service consultants to identify and accurately quote the cost for the most common repairs that the shop performs. It is a valuable tool to help service personnel quickly and accurately provide estimates for common light, medium, and heavy repairs. Preventive maintenance is one of the easiest items to sell to every customer because it is based on the manufacturer's scheduled vehicle maintenance.

NOTE: The service consultant should sell only what is needed. Be sure that the repairs and services recommended are based on sound practices.

COST OF REPAIR AND APPROVAL All work must be documented on the work order. It is important to have the customer's approval before working on the vehicle. This approval must be in writing or verbal approval if the telephone call is documented with the telephone number and time when the call was made. The customer could refuse to pay for unapproved repairs. In some areas, customers legally do not have to pay if they did not sign the repair order first.

These are very important steps, and if done correctly, they help build customer loyalty and avoid possible misunderstandings when the work has been completed.

SHOP MANAGEMENT SOFTWARE Shop management software allows shop owners and service consultants to evaluate work, prepare estimates, sell and buy vehicle parts, and control the whole operation using one integrated computer system. Garage software is convenient for all businesses as it offers multiple functionalities. It includes service assessment and vehicle tracking and generates point-of-sale invoices.

SUBLET PROCEDURES A sublet repair is a repair (or a part of a repair) performed by another person or company outside the shop. For example, an engine needing repair that also has a defective or leaking radiator would be repaired by the original repair facility, but the radiator may be sent to a specialty radiator repair shop. The radiator repair cost is entered on the work order as a sublet repair. Radio repair, radiator repair, and glass replacement are all examples of sublet repairs.

TECH TIP

Separate "Needed" from "Suggested"

The service consultant should always separate items into

- Service that is required because the part or system no longer meets factory specifications.
- Service that is suggested because those items are close to the end of their service life or are in need of replacement based on the extensive and informed experience of the technician.

ESTABLISH COMPLETION EXPECTATIONS The **appointment** is the best time to discuss when the customer will get their vehicle back. The appointment is the earliest point in the repair process where the customer expectations can be addressed. Appointments provide customer preferential treatment, effective shop management, qualified technician availability, bay space availability, proper equipment available, permits pre-ordering of parts, determine client's initial concerns, and allows more time for new customers.

The **appointment log** is created by the service consultant to record all the vehicles that are scheduled to come in on a particular day. There are now computer-generated logging and scheduling systems.

MANAGE AFTER-HOURS VEHICLES A drop off box with a write-up envelope can manage after-hours vehicle drop offs. The customer fills out a form and places the keys and form in an envelope and drops it in the opening of a locked box. Extending the business hours is another way to accommodate customers who work late.

MONITOR REPAIR/SERVICE PROGRESS A **repair order log** (or daily work control log) is used to track the repair and completion process or the lead time for each repair order. It provides an overview of all the vehicles that are in the shop on a given day.

DOCUMENT SERVICES PERFORMED/DECLINED An inspection form is a useful guide when conducting a vehicle inspection. By following the checklist, all the components can be tested in a systematic way to ensure that they are operational or serviceable. It also becomes a record for the shop to bring a customer's attention to needed service, or if a customer declines repairs, shows that the shop made the customer aware of them.

TRUST Once the service is completed, the results should be reviewed with the customer to confirm that the repairs have successfully resolved the customer's concerns and that the vehicle has been returned to the condition in which it was received. It is important to accurately communicate with the customer so they have a decent understanding of the service that was completed and so that any remaining questions are answered. This conversation should be based on **trust** and the relationship built with the customer during their experience with the shop. The service consultant must make sure the vehicle service was completed in a timely manner to maintain satisfied customers.

Having a conversation with the customer also gives the customer an opportunity to add something to the project that they may have forgotten. The added items may include those that were suggested at the time the work order was written. Once the original job has been completed, the customer may wish to have the additional work done when the vehicle is already at the shop.

THANK YOU NOTE Place a business card in the customer's car with a written thank you on the back. This little item seems as if it would not be important to customers, but it helps personalize the vehicle repair. Instead of a faceless service technician, the business card and/or note makes the transaction a personal one and helps build customer loyalty.

PRODUCT KNOWLEDGE

VEHICLE SYSTEMS KNOWLEDGE The service consultant should have a basic knowledge of vehicle systems and components. There is too much to cover within this chapter, but this text has other chapters that contain that information. ● **CHART 135–2** lists the subject areas and the related chapters to study.

Engine Systems (Includes Computer Controls, Mechanical, Cooling, Fuel, Ignition, Exhaust, Emissions Control, and Starting/Charging)	Chapters 15, 17, 21, 47, 49, 51, 80–82
Drive Train Systems (Includes Computer Controls, Manual Transmission/Transaxles, Automatic Transmission/Transaxles, and Drive Train Components)	Chapters 121–126, 128
Chassis Systems (Includes Computer Controls, Frames, Brakes, ABS, Traction Control, Suspension, Steering, Wheels, Tires, and TPMS)	Chapters 93, 105, 107–109, 111
Body Systems (Includes Computer Controls, Body Components, Glass, Heating and Air Conditioning, Electrical, Restraint and Accessories)	Chapters 46, 56, 57, 60

CHART 135–2

SERVICES/MAINTENANCE INTERVALS Online service information provides a systematic procedure and identifies special tools, safety precautions, and specifications relevant to the maintenance task. Maintenance and lubrication information includes topics such as:

- Maintenance reminder reset procedures
- Specified oil and other lubricant specifications
- Chassis lubrication points
- Component location
- Tire rotation methods
- Periodic vehicle inspection services (items to check and time/mileage intervals)
- Maintenance item part numbers, such as oil and air filter numbers, and specifications, such as oil capacity and tire pressures

WARRANTY, SERVICE CONTRACTS, BULLETINS, AND CAMPAIGNS/RECALLS Service consultants need to be familiar with the warranty of a vehicle that has one to be able to answer any questions customers may have. All new vehicles are provided with a warranty document when the vehicle is delivered.

NOTE: No vehicle manufacturer provides warranty coverage for tires. Tires are only covered for defects by the tire manufacturer.

Some shops or dealers sell a service contact through an insurance company and documents are also issued by the seller. These contracts like Car Shield generally require preapproval of repairs.

Service campaigns and recalls are usually conducted by original equipment manufacturers (OEMs) when a safety issue is discovered with a particular vehicle. Recalls are costly because they may require the repair of an entire model or production run of vehicles. This could involve many thousands of vehicles. Depending on the nature of the problem, recalls can be mandatory and enforced by law, or OEMs may choose to voluntarily recall these vehicles.

The service consultant should use the online service information to check for technical service bulletins for any concerns that enter the shop. Also check for recall campaigns or use the NHTSA website at https://www.nhtsa.gov/recalls by inputting the VIN.

The recall notice is sent to the customer and the OEM dealer. The service information indicates what campaigns are covered for that vehicle by VIN, but not the specific vehicle notice.

VEHICLE IDENTIFICATION Service work requires that the vehicle, including the engine and accessories, be properly identified. The most common identification is the make, model, and year of the vehicle. The VIN provides most of the information needed for identification.

Since 1981, all vehicle manufacturers have used a VIN that is 17 characters long. Although every vehicle manufacturer assigns various letters or numbers within these 17 characters, there are some constants, including

- The first number or letter designates the country of origin.
- The model of the vehicle is commonly the fourth and/or fifth character.

CHAPTER QUIZ

1. A service consultant receives a phone call from a customer. Which of these must the service consultant do before they hang up?
   - **a.** Answer all other calls
   - **b.** Make sure the customer was finished
   - **c.** Make sure they made their point
   - **d.** Pause for two seconds of dead air before hanging up
2. Two service consultants are discussing alternative transportation options for customers. Service Consultant A says that the shop should always provide alternate transportation for a customer under all circumstances. Service Consultant B says that many car dealers have vehicle rental companies nearby to help with transportation needs. Which service consultant is correct?
   - **a.** Service Consultant A only
   - **b.** Service Consultant B only
   - **c.** Both Consultants A and B
   - **d.** Neither Consultant A nor B
3. Which of these is a good reason for reviewing the vehicle service history?
   - **a.** It keeps the cost of repair low
   - **b.** It helps address concerns
   - **c.** It maximizes shop profits
   - **d.** To repeat the service
4. The performance of maintenance and service activities depends on the shop's ability to ______________.

EXHAUST SYSTEMS SPECIALIST (X1)

LEARNING OBJECTIVES:

After studying this chapter the reader should be able to:

- Discuss the purpose and function of an automotive exhaust system.
- Discuss the components of an automotive exhaust system.
- Describe exhaust system mounting hardware.
- Describe how to inspect the exhaust system.
- Discuss exhaust system repairs.
- Explain exhaust emission control systems.
- Discuss the exhaust system fabrication process.
- Discuss MIG welding.
- Discuss oxy-acetylene welding.
- Discuss flame types.

EXHAUST SYSTEM

PURPOSE AND FUNCTION The job of the automotive exhaust systems is to rid the internal combustion engine (ICE) of spent gases (the gases are left over from the burning of the hydrocarbon fuel, with oxygen, and nitrogen). The ICE draws in the fresh air charge that is needed for combustion and uses the exhaust system to remove what has been spent. Exhaust gases must be removed with as little resistance as possible. The cylinders will not fill with the proper air charge if combustion gas pressure builds up in the exhaust system.

Backpressure is the resistance to exhaust gas flow in the system, which is often due to restrictions, such as exhaust pipe blockage, mufflers, catalytic converters, or resonators. Exhaust systems that do not remove exhaust gases efficiently may have unwanted backpressure.

EXHAUST SYSTEM COMPONENTS

EXHAUST MANIFOLD The **exhaust manifold** bolts directly to the cylinder head and mates with the cylinder head exhaust ports. Inline engines are equipped with a single exhaust manifold, while "V" design engines have one exhaust manifold for each cylinder head. ● **SEE FIGURE 136–1**.

EXHAUST MANIFOLD REMOVAL The exhaust manifold must be cool before being removed. Penetrating spray is often needed on the mounting fasteners to get the nuts or manifold bolts off of the cylinder head. Some vehicles have secondary air injection (SAI) tubes and a check valve that may have to be removed. Often

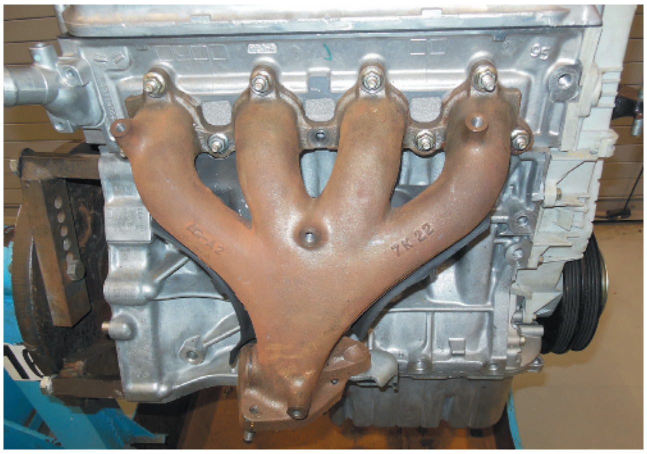

FIGURE 136–1 An exhaust manifold on a four-cylinder engine.

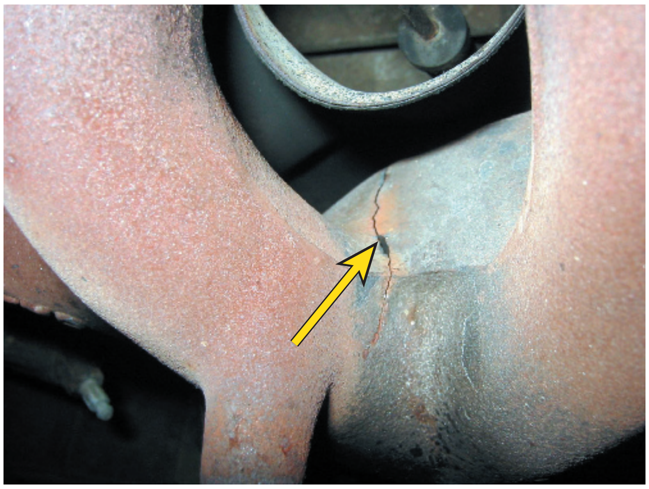

FIGURE 136–2 A cracked exhaust manifold is often hard to see because the manifold is covered by a heat shield.

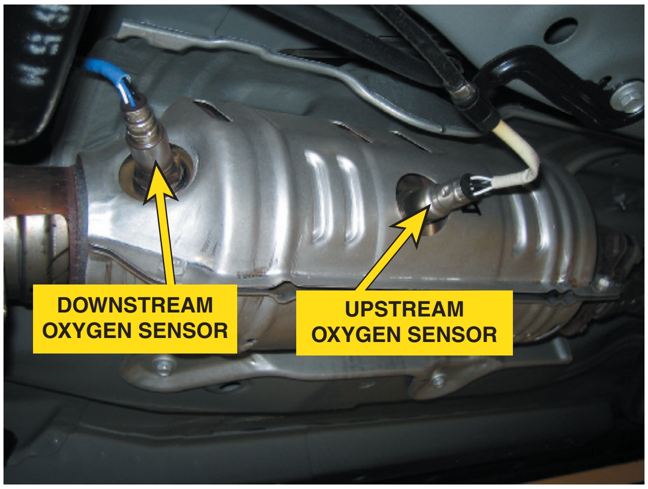

FIGURE 136–3 Upstream and downstream oxygen sensors are used to monitor the operation of the catalytic converter.

there will be tubing for the exhaust gas recirculation (EGR) that also needs to be removed.

EXHAUST MANIFOLD INSPECTION Carefully examine the exhaust manifold for cracks or other damage. ● **SEE FIGURE 136–2**.

Depending on the design of the manifold, some areas get hotter than others. Thoroughly clean off all dirt and old gasket material from the mating surface of the exhaust manifold. Check the cylinder head mating surface of the exhaust manifold using a straight edge and a feeler gauge and compare to the manufacturer specifications. If the mating surface of the exhaust manifold is warped or damaged, it may be necessary to resurface it or replace the exhaust manifold. Sometimes a gasket is available for these applications, which may take up for the warpage or damage. Also inspect the manifold studs for any corrosion or damage. Replace or repair the studs as needed.

CATALYTIC CONVERTER The **catalytic converter** converts harmful exhaust emissions into non-harmful compounds. The converter structure contains small amounts of rhodium, palladium, and platinum. When the converter is heated by the exhaust gasses, the three elements act as catalysts and convert the exhaust gases of hydrocarbon (HC), carbon monoxide (CO), and oxides of nitrogen (NOx) into harmless emissions such as water (H_2O), carbon dioxide (CO_2), and nitrogen (N_2). The catalytic converter can be clogged if an overly rich air fuel mixture overheats the converter and melts the substrate brick. The catalytic converter substrate or brick can melt or break into pieces if the engine over-fuels due to a misfire or defective oxygen sensor or air-fuel ratio (AFR) sensor.

The catalytic converter monitor of OBD II uses an upstream and downstream oxygen sensor to test catalyst efficiency. When the engine burns a lean air–fuel mixture, higher amounts of oxygen flow through the exhaust into the converter. The catalyst materials absorb this oxygen for the oxidation process, thereby removing it from the exhaust stream. If a converter cannot absorb enough oxygen, oxidation does not occur. The oxygen content after the converter is monitored by the downstream oxygen sensor. ● **SEE FIGURE 136–3**.

Some methods of testing the catalytic converter include the following:

- Use an infrared thermometer to determine whether a catalytic converter is working. The outlet temperature should be around 10% hotter than the inlet temperature. When the catalytic converter is not working, the inlet temperature is hotter than the outlet temperature.
- The **tap test** involves tapping on the catalytic converter with a rubber mallet. If the substrate inside the converter is broken, the converter will rattle.
- When the catalytic converter is being tested for contamination and operation, use a scan tool that can access mode 6 and look at the test results for each of the catalyst monitors. When using mode 6, research must be done for the specific codes that the manufacturer uses to identify each catalyst monitor, as well as the coding for the actual results.
- A digital storage oscilloscope (DSO) can be used to compare the upstream and downstream oxygen sensor patterns to determine whether the catalyst is working efficiently.

FREQUENTLY ASKED QUESTION

How Long Must a Shop Keep a Removed Catalytic Converter?

An aftermarket installer can only keep a catalytic converter after it has been removed from a vehicle for 15 days. In 1986, the U.S. Environmental Protection Agency (EPA) issued new guidelines for the construction, efficiency, and installation of aftermarket catalytic converters. EPA guidelines state that replacement converters may be installed only in the following situations:

1. Vehicles manufactured prior to 1996 must have more than 50,000 miles, and a legitimate need for replacement must be established and documented.
2. In cases of OBD II-equipped vehicles (1996 and later), the original equipment manufacturer's 8-year/80,000-mile warranty must have expired, and a legitimate need for replacement must be established and documented.
3. The vehicle is missing a converter.
4. A state or local inspection program has determined that the existing converter needs replacement.
5. Please note that federal law prohibits removal or replacement of a properly functioning original equipment catalytic converter.

MUFFLER The **muffler** is used in the exhaust stream to help quiet the sound of engine combustion. The muffler is a can or container with an inlet and an outlet pipe attached. Inside the muffler is a series of baffles designed to deflect the exhaust inside the muffler. The baffling or deflecting of the exhaust gases inside the muffler quiets the sound of combustion before the gases move out of the tailpipe.

In an exhaust system, pressure pulses create sound waves that travel down the exhaust pipe and into the muffler. The sound waves enter a reverse-flow muffler (most common type) through the center tube, bounce off the back of the muffler, and are reflected through a hole into the muffler main body. Then, they pass through more holes into another chamber and turn and exit the muffler outlet. Mufflers are designed so that the size of their chamber, tubes, and baffles allow the sound waves to cancel each other out, reducing engine noise. There are also straight-through mufflers that use perforations inside the muffler to break up the pulsations and glass insulation inside the muffler to absorb some of the pressure pulses. Straight-through mufflers are less restrictive and are used for performance-based engines. They do not reduce sound level as well as reverse-flow mufflers and may not be legal in your state.

NOTE: Some mufflers use a small hole in the lower rear part to drain accumulated water. About a gallon of water is produced in the form of steam for each gallon of gasoline burned. The water vapor often condenses on the cooler surfaces of the exhaust system unless the vehicle has been driven long enough to fully warm the muffler above the boiling point of water.

UNIVERSAL MUFFLER A universal muffler may require cutting existing pipes, pipe adapters, and new clamps and hangers. Using an original equipment manufacturer (OEM) exact fit replacement muffler eliminates the need for pipe adapters. A **pipe adapter** is used to connect nonstandard exhaust components to existing OEM components like the one used to connect the catalytic converter to the existing exhaust systems or connect one size pipe to another.

RESONATOR The **resonator** is similar to a muffler and is usually connected in the exhaust stream before the muffler. The resonator helps to quiet the sound of combustion before the exhaust gases reach the muffler.

TAILPIPE The **tailpipe** is the last pipe in the exhaust system; it carries the exhaust fumes out from under the vehicle and into the atmosphere.

EXHAUST SYSTEM MOUNTING HARDWARE

PURPOSE Mounting hardware is used to attach the exhaust system to the vehicle using brackets hangers and clamps.

CLAMPS **Clamps** are U-bolts that come in different sizes that correspond to the pipe diameter that secure the slip joint connections that are attached to some exhaust system components. Clamps may also be used to attach hangers in some applications. Ensure the inside pipe is fully inserted in the slip joint connection and the clamp is positioned around both pipes, but not too close to the edge of the outer pipe. Position the clamp so that the ends of the U-bolt will not contact other components or snag objects that may pass under the vehicle. Tighten the clamp only enough to secure the connection. Overtightening may distort the pipes, causing an exhaust leak.

HANGERS **Hangers** are O-ring or fabric devices that attach to brackets mounted on the underside of the vehicle to support the exhaust system. Some are welded to the exhaust system. Hangers can also be made of reinforced fabric that are bolted or clamp to the exhaust system. Hangers must be flexible enough to allow the exhaust system to expand as it gets hot and move with the torque of the engine. The hangers also isolate the vehicle from vibrations in the exhaust system. When installing exhaust system components, make sure to take the necessary steps to properly position them. Hangers should be used to support the exhaust system and not pull or force the exhaust system into position. Hangers that are used this way will be under constant stress and most likely break.

HEAT SHIELDS **Heat shields** are used to protect the underbody of the vehicle from excessive heat created by the exhaust system. Heat shields are usually riveted or screwed into the bottom of the vehicle floor pan above the exhaust system. ● **SEE FIGURE 136–4**.

EXHAUST SYSTEM INSPECTION

VISUAL INSPECTION Exhaust system inspection starts by raising and safely supporting the vehicle. Visually inspect the exhaust system for physical damage, holes, cracks, separated components, bulging muffler seams, and broken or missing clamps and hangers. A catalytic converter that appears bluish or brownish indicates that it has been overheated. Wiggle the exhaust system at various points to look for excessive movement caused by broken or cracked connections or broken or missing hangers. Tap on the exhaust system components with a mallet. An exhaust component in good condition will make a solid metallic sound, while a component that is worn out will have a dull sound. Rattling noises can be caused by loose heat shields, loose clamps, or an exhaust pipe interfering with another exhaust component. When tapping on the muffler or catalytic converter, listen for the sound of loose rust particles.

DIAGNOSING NOISE The first step in diagnosing a noise or exhaust leak under the vehicle is to discuss the noise with the vehicle owner because the owner or driver is the best resource to find out the nature of the noise. Exhaust system components can fail due to physical or chemical damage. The exhaust system is subject to damage and wear from dirt, stones, water, and other road hazards. It can also rot out from the inside from moisture or internal corrosion from poor combustion. Many vehicles are driven short distances, so the exhaust system never gets warm enough to evaporate the moisture. Whether caused by physical or chemical damage, the result is cracks, holes, or other damage to the exhaust system that can cause excessive noise and can allow harmful exhaust gases to enter the passenger compartment. Exhaust system damage can result in a restriction. A blockage can be caused by physical damage, such as a dented exhaust pipe, or clogged muffler, resonator, or catalytic converter. A restriction can also be caused by a collapsed inner exhaust pipe.

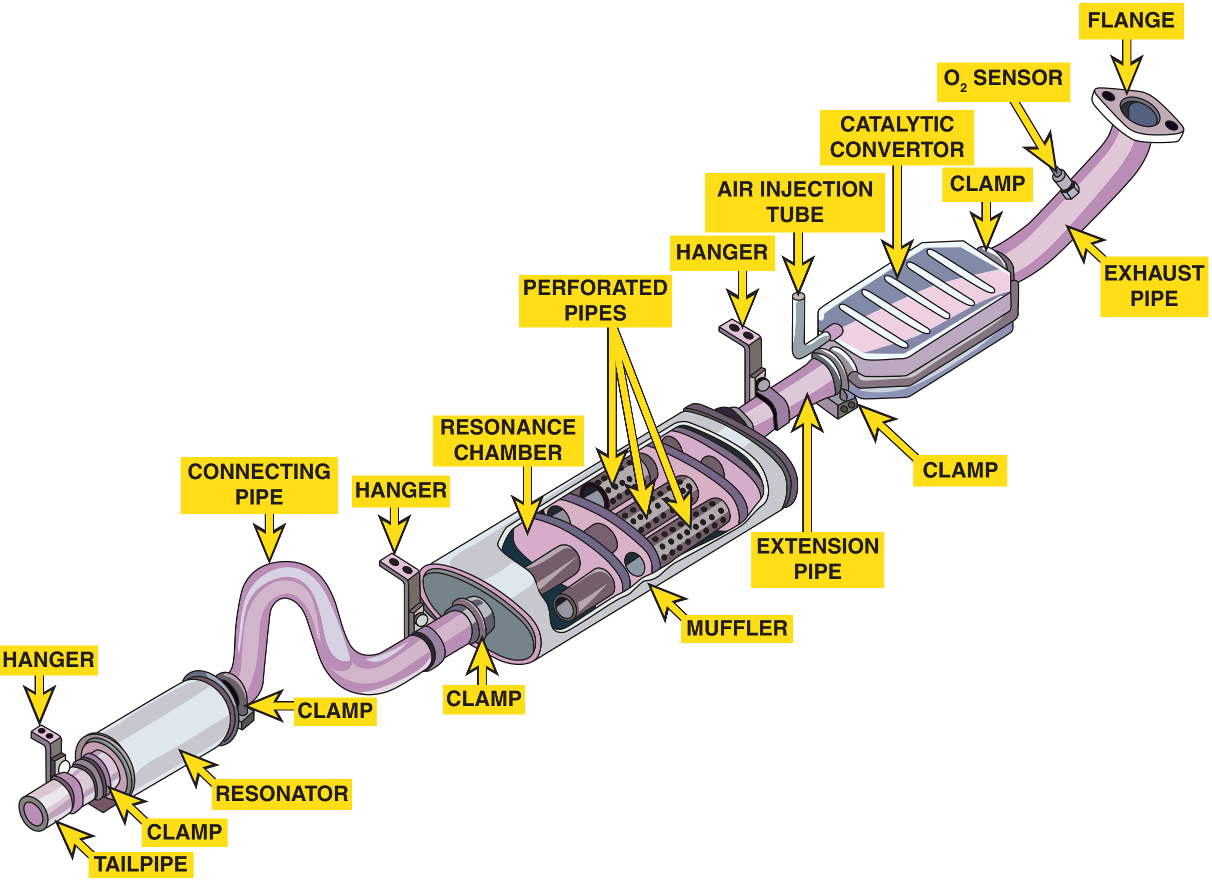

FIGURE 136–4 An exhaust system has many individual parts Each has its own purpose and function, and all must be working as designed.

WARNING

Engine exhaust contains carbon monoxide (CO), which can cause headache, nausea, and drowsiness, and if enough is inhaled, it can even result in unconsciousness and death. Any exhaust system damage that results in exhaust leakage must be repaired as soon as possible.

TECH TIP

A Rubber Mallet Is a Technician's Friend and Helper

Some vehicles use double wall tubing for exhaust pipes. The inside tube can collapse or rust inside the outer tube and cause a restriction, even when the outer tube looks good. Tap on the exhaust pipes with a rubber mallet and listen for rattling or rust breaking loose, which would indicate a problem inside the pipe. A restricted exhaust system can cause low power, poor fuel economy, and, if it is completely clogged, the engine may not run at all.

CHECKING FOR EXHAUST LEAKS Black streaks or soot on the outside of a component can be signs of leakage. If the source of exhaust leakage is not seen, start the vehicle and listen carefully for exhaust leaks at all joints and seals. Never overlook any welded connections because they can crack and leak as well. A small exhaust leak will make a hissing or popping noise. A significant exhaust leak can show up as a diagnostic trouble code (DTC) set for a poor-performing turbocharger or catalyst.

A tapping sound that may sound like valve train noise can be an exhaust leak at the exhaust manifold connection to the cylinder head. To check for leaks, perform the following steps:

STEP 1 Use a rag to block off the exhaust flow from the tailpipe. If the exhaust system is not leaking, pressure will build and force the rag out of the pipe. If there are leaks in the exhaust, hissing will be heard from the exhaust system through the leaks. It may be necessary to have an assistant perform this test (block off the tailpipe with a rag) while the technician listens for exhaust leaks.

STEP 2 Use a technician's stethoscope to help pinpoint small leaks while this test is being performed.

STEP 3 Use a smoke machine with an exhaust pipe adapter to fill the exhaust system with smoke. With the engine off, any signs of smoke will be pinpointed.

ELECTRONIC LEAK DETECTOR TESTING Obtain an electronic exhaust gas leak detector, which can be purchased at a reasonable cost. The first step is to test for a known gas such as at the tailpipe to verify the tester is capable of measuring gas. Raise the vehicle on a lift or safety stands using a floor jack and go down the exhaust system from the turbocharger to the tailpipe and look for leaks. If any leaks are found, take the necessary steps to repair the exhaust system.

SOAPY WATER TESTING FOR EXHAUST LEAKS Obtain an empty spray bottle and mix water and a small amount of dish washing detergent to make a soapy water solution. Raise the vehicle on a lift or safety stands using a floor jack and check the exhaust system starting at the turbocharger. Spray the joints and pipe looking for soapy bubbles. If any leaks are located, take the necessary steps to repair the exhaust system.

EXHAUST SYSTEM BACKPRESSURE Excessive exhaust system backpressure can cause poor engine breathing due to a clogged or restricted exhaust system. A low power complaint with a whistling sound may indicate an exhaust system restriction. High exhaust backpressure can cause several destructive engine operating conditions, including the following:

- High exhaust valve temperatures can be caused by an inadequate flow of fresh intake air over the exhaust valve, especially during the valve overlap period. High exhaust valve temperatures can cause a valve to burn, resulting in an engine misfire.
- Overheating of cooling systems can be caused by transfer of heat energy from slow-moving exhaust gases lingering near the exhaust ports into the cylinder head.
- Excessive crankcase pressure can result from exhaust gas pressure retained in the cylinder that will leak past piston rings and enter the crankcase.
- Increased engine blow-by gases can cause the combustion gases to leak past the piston rings into the crankcase.
- High exhaust emissions due to poor combustion quality can be caused by high exhaust backpressure.
- Low turbocharger boost pressure caused by high exhaust backpressure. Turbine speed is dependent on the pressure drop between the turbine inlet and outlet, and high exhaust pressure reduces the pressure differential across the turbine. This causes turbocharger speed and boost pressure to fall.

TESTING BACKPRESSURE Two methods can be used to check for exhaust system backpressure:

1. **Vacuum Measurement at Intake Manifold** A vacuum gauge measures engine vacuum with the engine running and installs to a port on the intake manifold. To measure engine backpressure, install a vacuum gauge into an intake manifold port. At idle, the vacuum will be from 17 to 22 inches of mercury (in. Hg). Raise the engine speed by opening the throttle by hand or with a scan tool to about 2,000 to 2,500 RPM. When the engine is kept at a constant speed, the manifold vacuum on the gauge will drop gradually if there is a restriction. ● **SEE FIGURE 136–5**.
2. **Exhaust Manifold Pressure Measurement** Back pressure can be measured directly by installing a pressure gauge into an exhaust opening. A manometer is the best gauge to use for this test. The upstream oxygen or air fuel ratio sensor is a convenient place to install the pressure gauge. Using a modified or discarded oxygen sensor is an easy way to connect the gauge. The maximum backpressure should be less than 1.5 PSI (10 kPa) at idle and less than 2.5 PSI (17 kPa) at 2,500 RPM.

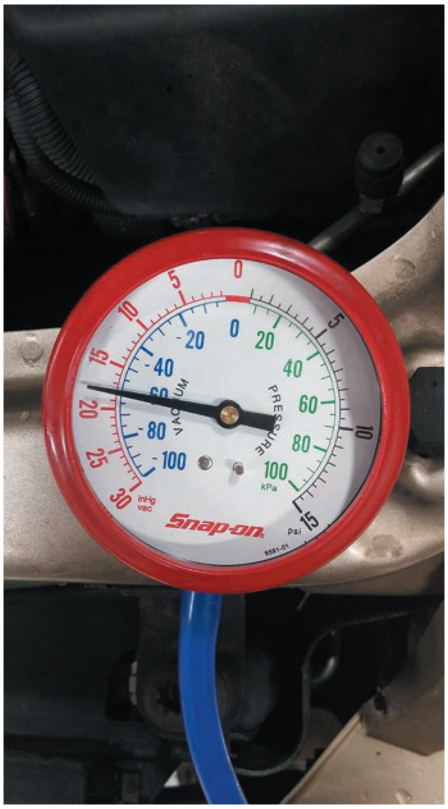

FIGURE 136–5 A vacuum gauge can be used to determine whether an engine has an exhaust restriction.

EXHAUST SYSTEM REPAIR

RUST AND CORROSION Always wait until the exhaust system is cool to the touch before beginning exhaust system repairs to help avoid possible personal injury. The greatest hindrance found during exhaust repair is rust and corrosion. To help address rust and correction problems, keep in mind the following:

- Nuts rust solid to clamps, and exhaust manifold studs and other components rust together at their connection points.
- Threaded fasteners that must be reused can be soaked with penetrating oil or heated for removal.
- Always use six-point sockets to remove exhaust fasteners, as a 12-point socket will round off the corners of a corroded fastener.
- Support the exhaust system with a tall jack (safety) stand and remove the necessary clamps, fasteners, and hangers from the component being replaced.
- Remove the nuts from the exhaust manifold studs, and pull the pipe flange away from the studs.
- Remove the exhaust pipe from the catalytic converter and remove the exhaust pipe from the vehicle.
- Inspect the exhaust manifold studs for corrosion. It is a good idea to replace the studs.

Many exhaust system components use a **slip joint** connection. These connections use an inner pipe that fits inside an outer pipe or an inner pipe that fits inside the muffler. When separating

TECH TIP

Use a MIG Welder

A time-saving option is to use the stud welding attachment that is available on some MIG welders. With this tool, a new stud can be welded to the exhaust manifold without removing the manifold from the vehicle.

these connections, be careful not to damage the parts that are not being replaced. On these types of connections, if the part that is being replaced is the inner pipe, the pipe can be cut in half just outside the outer pipe using a hacksaw, air chisel. or cutoff wheel. Cut a slit in the remaining part of the pipe, which will allow it to be pulled from the muffler or outer pipe. There are slitting tools that can be attached to air tools that are used for this purpose. When replacing the muffler outer pipe, use the slitting tool to cut the outer pipe open, which will allow it to be removed from the inner pipe.

If replacing a component that has been welded together, is not necessary to weld the replacement component in place. Adapters are available that allow a slip joint connection and clamps to be used to secure the component. When installing a new pipe into an old muffler outer pipe, the new pipe may not fit because the muffler or outer pipe opening was distorted, damaged, or overtightened. A cone-shaped pipe-shaping tool and a hammer can be used to make the pipe opening round. A pipe expander can also be used to smooth out or enlarge the diameter of the pipe. Install the expander and tighten the bolt with the socket ratchet until the pipe has been enlarged. Install clamps and hangers, but do not tighten them yet if installing a new exhaust pipe using a new gasket at the exhaust manifold. Replace the exhaust pipe flange nuts with brass, which will not rust to the studs. Make sure the exhaust system is properly aligned and there is enough clearance between the system and all underbody components. Tighten all clamps and hangers, but do not overtighten clamps because this could distort the pipes and create a leak. Install any heat shields or other components that were removed. Start the engine and check for leaks.

POWERTRAIN MOUNTS Broken **powertrain mounts** can cause stress on the exhaust system to wear and even cause components to break. Exhaust system hangers are designed to allow normal system movement with the torque of the engine. If a broken mount allows the powertrain to move more than intended, the exhaust system can be damaged. On a rear-wheel-drive (RWD) vehicle, to inspect the mounts, carefully raise the engine just high enough to remove weight from the mount. This will place a slight tension on the mount to see if it is broken. Repeat this process at the transmission to relieve pressure on the rear mount reattached to the cross member. On a front-wheel-drive (FWD) vehicle, perform the same procedure by raising the powertrain at support points along the subframe. With the weight removed from the mount, look for signs of cracking or splitting in the rubber section. ● **SEE FIGURE 136–6**.

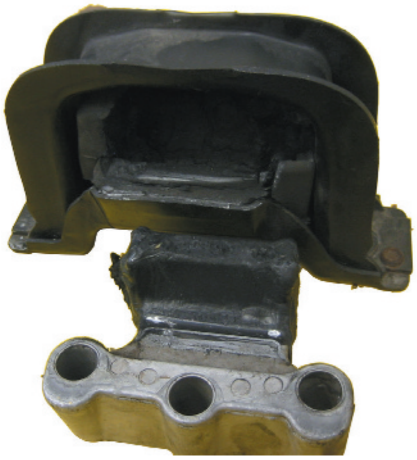

FIGURE 136–6 All powertrain mounts should be carefully inspected for damage. This mount has separated from the support frame and needs to be replaced.

EXHAUST EMISSION CONTROL

VEHICLE IDENTIFICATION NUMBER The vehicle identification number (VIN) is a 17-character code that identifies the vehicle. In 1981, the National Highway Traffic Safety Administration of the United States standardized the format. It required all on-road vehicles sold to contain a 17-character VIN. ● **SEE CHART 136–1**.

VEHICLE EMISSIONS CONTROL INFORMATION (VECI) The **Vehicle Emissions Control Information (VECI)** label is located under the hood of the vehicle. The VECI label (sticker) can be located on the bottom side of hood, the radiator fan shroud, the radiator core support, or the strut towers. The VECI label usually includes the following information:

- Engine identification
- Emissions standards that the vehicle meets
- Spark plug type and gap
- Valve lash, if adjustable
- Major emission control systems on the vehicle
- Emission calibration codes

VEHICLE EMISSION SYSTEMS The exhaust system specialist needs to have a working knowledge of emission control systems that are used on today's vehicles. This information can be found in other chapters. ● **SEE CHART 136–2.**

TECH TIP

Always Comply with Exhaust System Repair Regulations

Any and all exhaust system repairs must comply with federal state and local laws including the following:

- Comply with the standards for the proper operation of the EGR, oxygen sensors, and turbocharger system, if equipped.
- Verify that the catalytic converter requirements are met for the type and location, as well as proper record keeping if a converter is replaced.
- Ensure that the exhaust system is routed correctly, and that the exhaust exits the vehicle according to regulations and is leak free.

EXHAUST SYSTEM FABRICATION

PIPE BENDING There are three methods of bending exhaust pipes:

1. **Program cards** are provided by the pipe-bending equipment manufacturer and contain all the information necessary to duplicate the exhaust pipes found on most vehicles. The number of the program card is found by looking up the make, model, year, and engine in the card catalog. There are separate cards for each pipe in the exhaust system. The program card lists the length and diameter of the pipe, the distance between the center of the bends, and the rotation and depth of the bends in degrees. There may also be remarks that describe bending instructions for peculiar applications. Using this information, the technician can make a pipe identical to the one originally installed by the vehicle manufacturer.
2. **Pattern bending** means measuring and comparing the old exhaust pipe to make a new one. This may be necessary when making a pipe for an older or low-production vehicle for which no program card exists.
3. **Custom bending** is necessary when there is no program card or existing pipe. Applications for which custom may be necessary include installing other than the original.

SAFETY TIP

Safety Precaution When Operating a Pipe Bender

When bending exhaust pipe, always follow the instructions from the bending tool manufacturer and the following:

- Always wear eye protection, gloves, and protective shoes or boots.
- Do not wear loose-fitting clothing that could be snagged by the machine or a pipe.
- Make sure the area around the machine inside the length of the pipe being bent is clear.
- The pipe will move as it is bent, so make sure that the pipe will not contact anything during the bending procedure.
- Do not operate the machine without the safety guards in place, and keep hands clear of the bending dies when the machine is in motion.
- Use caution when handling the ends of pipes that have just been cut, as they can be sharp.

PROGRAM BENDING To use a program card to bend pipe, perform the following steps:

STEP 1 Using make, model, year, and engine information, look up the program card in the card catalog for the pipe that is needed, and remove the card from the card file. Thoroughly read and understand all the information on the card before proceeding with the bending operation.

STEP 2 Select a straight length of pipe in the outside diameter listed on the program card, which is 12 inches longer than the cutoff point listed on the card.

STEP 3 Wipe the excess oil and dirt from the pipe and turn on the bending machine. Install the dies and back shoes on the machine that correspond with the pipe diameter and the radius of the first bend that will be made.

STEP 4 The die fits on the hydraulic ram that pushes against the pipe during the bending operation, while the back shoes mount on the swing gates and clamp the pipe in position during bending and also form the outside radius of the pipe.

STEP 5 Position the pipe on the machine, seam side up, and engage the die using the ram until the pipe is held firmly, with the greater portion of the pipe extending from the left side of the machine.

STEP 6 Using a sharpie pen, mark the points of the pipe where the bends will be made, as listed on the program card. At each point, position the marker on the pipe and then rotate the pipe until the mark is completely around the pipe. The last mark made is the final cutoff point for overall length.

STEP 7 Release the pipe from the machine and reposition it so it extends from the right side of the machine, seam side up, with the first bending mark between the back shoes. Engage the die until the pipe is firmly held in place. Position the rotation dial at the right end of the pipe, at least 12 inches from the final bend. Rotate the dial so that the indicator points to zero, which should also line up with the pipe seam. Secure the dial to the pipe.

STEP 8 Adjust the depth-of-bend setting on the machine according to the program card. Operate the machine until the bend is made. Some machines must be operated manually, while others will automatically make the bend, reverse the ram, and then stop, with the touch of a button.

WARNING

Read, understand, and follow all of the operating instructions of the pipe bender being used to help prevent personal injury.

PATTERN BENDING To use a pattern bending to bend pipe, perform the following steps:

STEP 1 Measure the outside diameter of the old pipe. Dies come in different radiuses, so fit the bends of the old pipe into various radius dies in that diameter until the necessary die is identified. Install that die and back shoes that will be used for the first bend on the pipe bending machine.

STEP 2 Measure the overall length of the old pipe and select a new pipe that is long enough for the job.

STEP 3 Place the new pipe in the bending machine and position it so the largest portion extends from the right side of the machine. Place the old pipe over the back shoes so that the center of the first bend is between the shoes. Push the new pipe from the left side of the machine until the end of the pipe lines up with the old pipe.

STEP 4 Position the first bend of the old pipe on top of the back shoes parallel with the new pipe, and gradually bend the new pipe until the bends of both pipes match. Retract the ram and move the pipe to the left. Place the old pipe on top of the back shoes and line up the center of the second bend with the center between the back shoes.

STEP 5 Line up the first bend on both pipes, then rotate the new pipe until it is parallel with old pipe. Clamp the new pipe into position with the die.

STEP 6 Position the second bend of the old pipe on top of the back shoes and gradually bend the new pipe until the die bends of both pipes match. Repeat bending operations until the last bend has been made. When all bends are completed, cut the pipe to match the length of the old pipe. Finish the ends of the pipe, as required. ● **SEE FIGURE 136–7**.

CUSTOM BENDING Since there is no program card or old pipe to use, inspect the area where the pipe is supposed to fit and try to visualize the pipe routing in relation to the components under the vehicle. Look for things like heat shields on the underside of the vehicle and old hangers that can indicate how the pipe was routed. Hold a length of stiff wire (welding rod works well) up to the exhaust system component to which the new pipe will be attached. Bend the wire to match the projected routing of the new pipe, making sure to allow enough clearance around other components. To make the new pipe, use the wire in the same manner as the old pipe described under pattern bending. Once the new pipe is made, perform a test fit under the vehicle to make sure the routing is as projected and that there will be no interference with other components.

END FINISHING Exhaust system components are connected in a variety of ways. A common type is the slip-joint connection, where an inner pipe fits inside an outer pipe. If both pipes are the same diameter, the end of one pipe must be made larger to fit over the other pipe. Other connections use gaskets and require that the end of the pipe be flared or flanged to make a good seal.

To expand, reduce, or flare the ends of exhaust pipes, pipe bending machines have swaging and expanding attachments. These attachments come with tooling that can end finish a pipe for any kind of connection. Besides the expansion for slip joint connections, other common end finishes are flares, flat flares, male ball joints, female ball sockets, flare flanges, and flat flanges.

Follow the manufacturer's instructions for pipe positioning, tooling combinations, and swaging and expanding procedures. If a flange is used to secure a pipe, such as an exhaust pipe to an exhaust manifold, be sure that the flange is installed before the end of the pipe is flared.

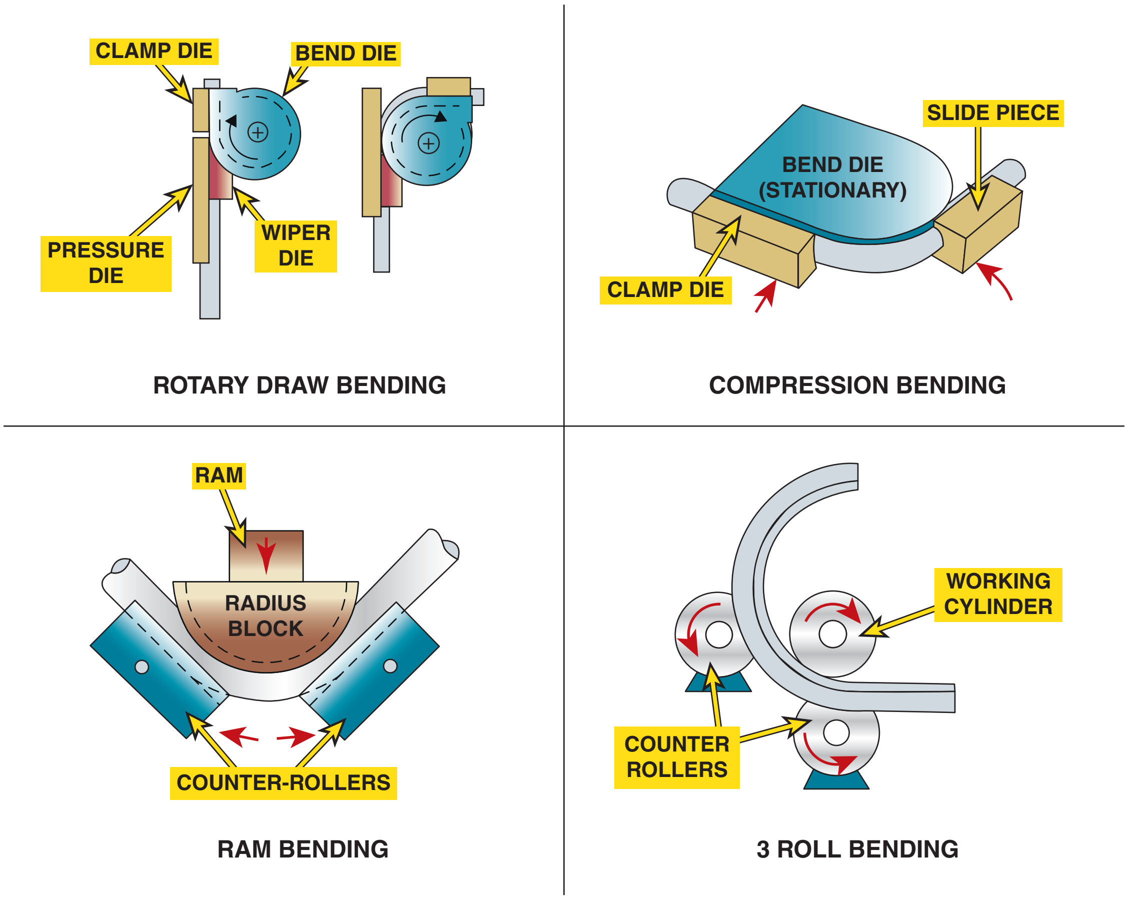

FIGURE 136–7 Exhaust pipe forming and bending can include rotary draw bending, compression bending, ram bending, or three roll bending.

MIG WELDING

TERMINOLOGY **Metal inert gas (MIG)** welding is an arc welding process that uses a continuous solid wire electrode heated and fed into the weld pool from a welding gun. The two base materials are melted together forming a joint. The gun uses a shielding gas around the electrode to protect the weld pool from oxidation. The MIG welder is currently used for welding panels and structural components together. MIG welding can repair high-strength steel without harming or weakening it.

OPERATION An arc is struck between the end of a wire electrode and the workpiece, melting both of them to form a puddle of molten steel, called the **weld pool**. The wire provides both the heat source due to the arc at the wire tip and filler metal. The wire is fed through a copper contact tube (contact tip) that conducts welding current into the wire. The weld pool is protected from the surrounding atmosphere by a shielding gas fed through a nozzle surrounding the wire. Shielding gas selection depends on the material being welded and the application and is usually CO_2 or argon or a combination. The wire is fed from a reel by a motor drive, and the welder moves the welding torch along the joint line. The process offers high productivity, as the wire is continuously fed. ● **SEE FIGURE 136–8**.

OXY-ACETYLENE WELDING

OPERATION Oxy-acetylene welding is used for welding, cutting, and heating to normalize metal, to shrink metal, to forge or shape metal, and to solder. The gases used for the oxyacetylene welding process are oxygen and acetylene. When mixed in the proper ratios using approved equipment, these two gasses produce a flame that is hot enough to melt most metals.

The welding and cutting set consist of the following:

- Oxygen cylinder
- Acetylene cylinder
- Hand truck to hold the cylinders
- Acetylene and oxygen regulators
- Hoses
- Welding torch (cutting attachment)
- Friction lighter

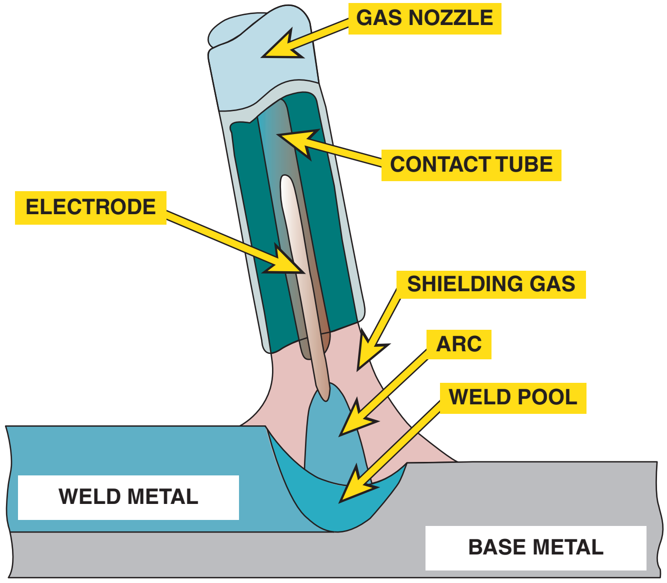

FIGURE 136–8 When using a MIG welder, create a weld pool and move the pool to create an even weld.

WARNING

If oxygen comes into contact with oil or grease, it will burst into flame. Make sure hands and gloves are free of oil and grease before handling any cylinders.

OXYGEN CYLINDER The oxygen cylinder is made from high-grade steel and is a seamless design and painted blue. They range in size from less than 20 cubic feet to greater than 300 cubic feet and contain compressed oxygen at pressures as high as 2,200 PSI (15,200 kPa). Cylinders have valves and are fitted with a screw on a steel cap that protects the cylinder valve. The safety cap MUST always be used during any cylinder movement or replacement. **SEE FIGURE 136–9**.

Open the cylinder valve and then close it before installing the regulator to clear the valve of any dirt. With the regulator installed, always crack the cylinder valve open first, then open it fully. This lessens the chance of recompression that is caused by high cylinder pressure entering the regulator, heating it up and damaging the regulator

ACETYLENE CYLINDER Acetylene cylinders are under pressure and are painted black or red. They are made of steel, have cylinder valves, and range in size from 10 to 400 cubic feet. The cylinders contain a porous filler material that is wetted with acetone and that allows the acetylene to safely be contained in the cylinder at 250 PSI (1,724 kPa). Always use an acetylene cylinder in the upright position so liquid acetylene is not drawn out of the tank. Only open the cylinder valve 1 to $1\frac{1}{2}$ turns, leaving the valve wrench on the valve if it has to be shut off quickly. Acetylene should never be used at a pressure that exceeds 15 PSI (103kPa) as it becomes highly unstable, which could cause it to decompose and explode.

REGULATORS The pressure in a full acetylene cylinder is about 250 to 2,200 PSI (1724 to 15,170 kPa) in a full oxygen cylinder. Regulators are used to adjust the high oxygen and acetylene pressures to lower working pressures for torch use. The regulator maintains a steady working pressure as the cylinder pressure drops. Regulators admit the high cylinder pressure through a valve, which is operated by a flexible diaphragm. When turning the regulator adjusting knob in or out, it causes a spring to operate the diaphragm to open or close the valve. When turning the adjusting knob in, the flow and pressure are increased. When turning it out, the flow and pressure are decreased.

Oxygen and acetylene regulators connect differently to their cylinders so they cannot be mixed up. Oxygen cylinder regulators have right-hand threads and acetylene cylinders use left-hand threads. There is a groove around fuel connections that indicates a left-handed thread. Finally, all acetylene regulator outlet (low-pressure) gauges have the gauge scales marked in red

starting at 15 PSI (103 kPa). This is to act as a reminder not to use acetylene at pressures over that marked in red.

Before opening the supply cylinder, check the adjusting screw to see if it is released and then open the cylinder valve. To adjust the working pressure, the valves on the torch body should be opened slightly as the adjusting screw is turned to adjust the regulator pressure that is required for the job. When a regulator is not being used overnight or is idle for a long period, the pressure should always be relieved on the delivery pressure valve seat.

HOSES The cylinder regulators and torch are connected using double-line rubber hoses. Double-line hose is known as type VD. The oxygen line is green, and the acetylene or fuel line is red. Hoses are available in four sizes, 3/16-, 1/4-, 3/8- and 1/2-inch I.D. The different grades of double-line hose used for acetylene are as follows:

- Non-oil resisting rubber cover
- RM (carries both a non-oil and flame and an oil-resisting cover for use with all fuel gases and acetylene)

Grades R and RM should be marked for acetylene only. Grade T should be marked fuel or acetylene gas. All hoses are marked to their service level (light, standard, or heavy). The date of manufacture is also marked at a maximum working pressure (200 PSI) along with nominal I.D size and if it meets RMA/CGA IP-90 (Rubber Manufactures Association, Compressed Gas Association) specifications for rubber welding hose. The hose fittings are marked as right- or left-handed threads. Single line hose come in 3 grades: L, light duty, S, standard duty, and H, heavy duty. Hoses are limited to a working pressure of 200 PSI.

CHECK VALVES Acetylene and oxygen must mix to be combustible. This must only take place at the torch mixer or the torch tip. Due to improper operation, sometimes acetylene and oxygen can feed back into the hoses and cause combustion in the hoses or regulators. *Check valves* are installed between the hoses and the torch to prevent this back flow. Check valves must be used with all oxy-acetylene torches.

TORCH The torch consists of a handle, oxygen, and acetylene gas valves and a mixing chamber. Welding tips or a cutting attachment can be used with the handle to weld, heat, or cut metal. Oxygen and acetylene gas flow through tubes inside the handle that blend in the mixing chamber or tip. It is at the tip where the mixed gases are ignited. Oxygen and acetylene enter the torch at about equal pressures. The injector type is used when acetylene

FREQUENTLY ASKED QUESTION

What Is a flashback?

A **flashback** is a rapid high-pressure flame in the hose, which can occur if there are not any check valves or the check valves fail to operate due to improper installation. Once a flashback starts, check valves cannot stop it. The flashback arrestor connects the same as the check valves in the hose at the torch or regulator and contains a trap that is spring loaded that cuts off the gas flow in the event of a flashback. Both check valves and flashback arrestors should be included on every oxy-acetylene setup.

FREQUENTLY ASKED QUESTION

What Causes a Backfire?

A **backfire** can take place with improper torch operation. The flame will go out with a loud snap or pop. The torch valves should be turned off and connections and valves checked for leaks. If everything is normal, relight the torch. Backfires are caused by the following:

- The tip is touching the work.
- The tip is overheated or dirty.
- Gas pressure is too low.
- The torch head or tip are loose.
- The seal between the torch body and mixing chamber is leaking.

gas pressures measure less than 1 PSI (7kPa). The oxygen at high pressure pulls the acetylene into the mixing chamber.

FLAME TYPES

NEUTRAL FLAME The **neutral flame** is generally used for welding and burns about one part oxygen to one part acetylene. Adjust the torch until the inner cone is blunt and the feathery edges have disappeared. A typical neutral flame burns at 5900°F (3260°C).

OXIDIZING OR EXCESS OXYGEN FLAME The **oxidizing flame** is used for brazing and is obtained by opening the oxygen valve slightly more than the neutral flame. The inner cone gets shorter and pointed and it becomes somewhat purple in color. Flame temperature is about 6300°F (3482°C). ● **SEE FIGURE 136–10**.

CARBURIZING FLAME The high acetylene or **carburizing flame** is the one most commonly used by automotive technicians to heat parts or to solder. More acetylene is burned than oxygen, so the inner cone has a feather. The inner cone is also white. The envelope around the carburizing flame has the same look as the neutral flame and the temperature is about 5700°F (3154°C).

OXY-ACETYLENE TORCH SAFETY

- NEVER use acetylene gas at pressures higher than 15 PSI (103 kPa).
- NEVER use oil or grease on or around oxygen equipment.
- NEVER use oxygen or acetylene to blow dirt or dust off of equipment.
- ALWAYS use a flint striker to light the torch; never light a torch with matches or a butane lighter.
- When opening an oxygen or acetylene valve, always crack it open first.
- Make sure regulators have their adjusting screws released by turning them CCW before opening the cylinder valves.
- Stand to the side of the regulator, NEVER in front of it, when opening the cylinder valves.
- ALWAYS wear OSHA-approved welding goggles (shield) and gloves when using an oxy-acetylene torch.
- ALWAYS have a fire extinguisher handy when using an oxy-acetylene torch.
- ALWAYS replace the cylinder caps when finished using the cylinders.
- Do not rely on the cylinder color to identify the gas, because some welding equipment suppliers may use different color codes.
- ALWAYS use the right regulator for the gas.
- ALWAYS use cylinders in an upright position only.
- NEVER store gas cylinders in temperatures above 130°F (54°C)
- ALWAYS keep the valve wrench on acetylene cylinder valve when in use.
- ALWAYS be aware of others around when using a torch.
- ALWAYS open the valve a maximum of 1½ turns.
- NEVER carry butane lighters, matches, or other flammable objects while heating, welding, or cutting.
- NEVER store gas cylinders in temperatures above 130°F (54°C)
- NEVER let welding hoses come into contact with the torch flame or sparks from cutting.

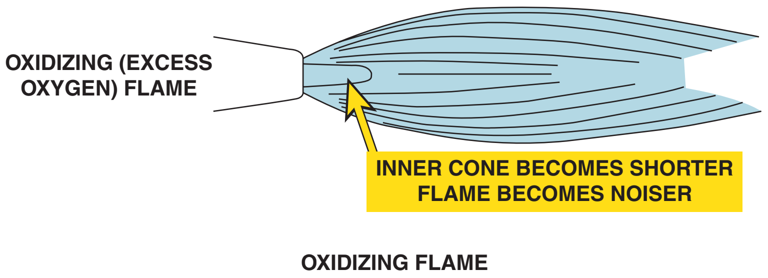

FIGURE 136–10 An oxidizing flame is hotter than a neutral flame and is identified by the short inner flame cone.

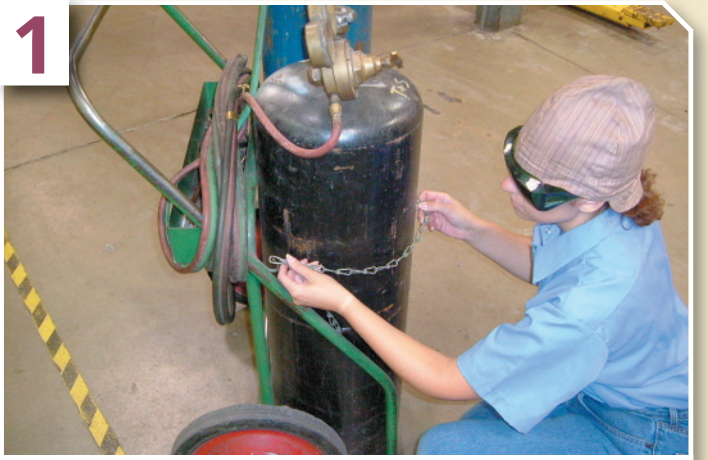
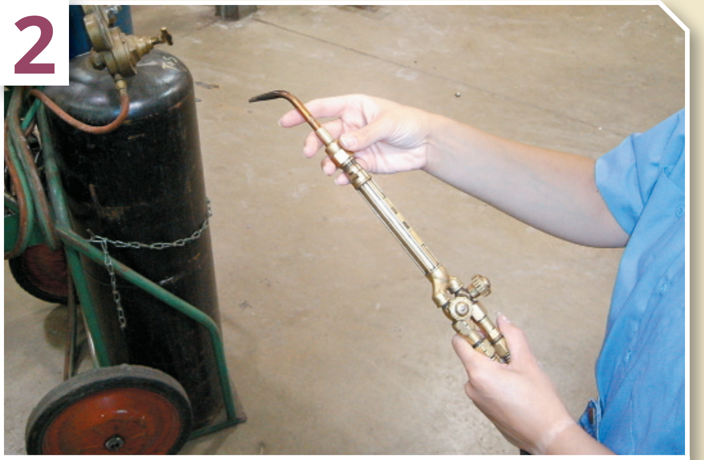
SETUP AND LIGHTING A TORCH

1



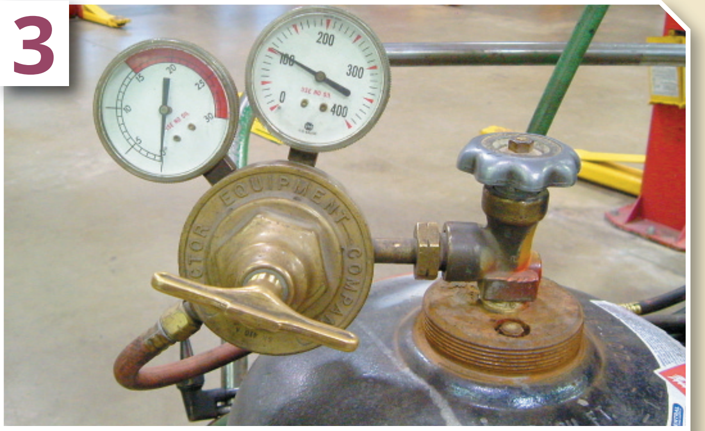
Inspect the cart and make sure the tanks are chained 1 properly before moving it to the work location.

2



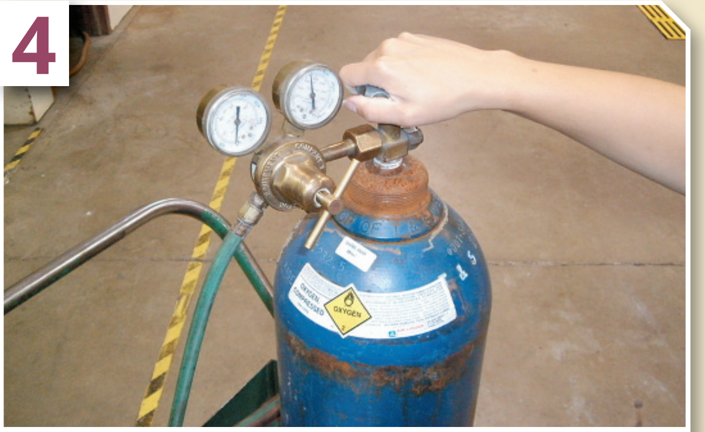
Start by attaching the appropriate work tip to the torch handle. The fitting should only be tightened hand tight. Make sure the valves on the torch handle are closed at this time

3



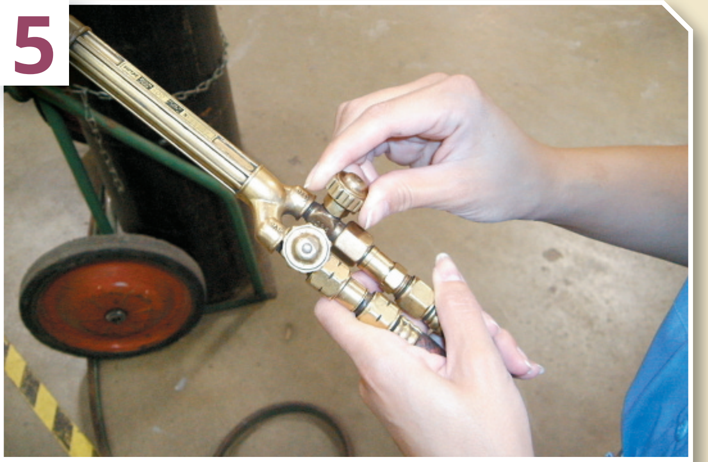
Each tank has a regulator assembly with two gauges. The high-pressure gauge shows tank pressure, and the low-pressure gauge indicates working pressure.

4



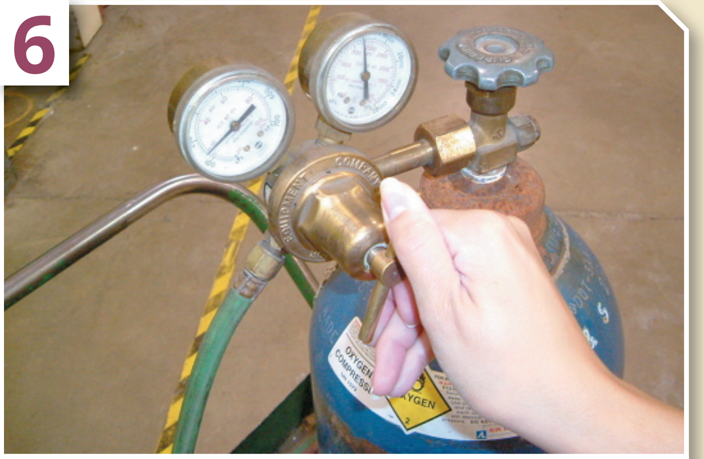
Open the oxygen tank valve fully open, and open the acetylene tank valve ½ turn.

5



Open the oxygen valve on the torch handle ¼ turn in preparation for adjusting oxygen gas pressure.

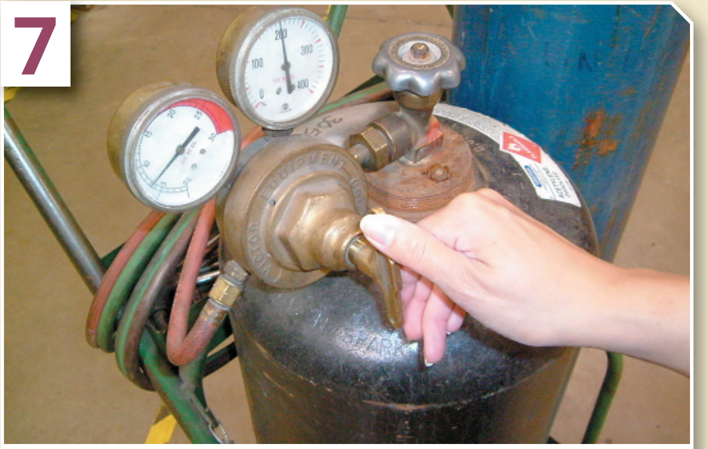
6



Turn the oxygen regulator valve clockwise and adjust oxygen gas pressure to 20 PSI. Close the oxygen valve on the torch handle.

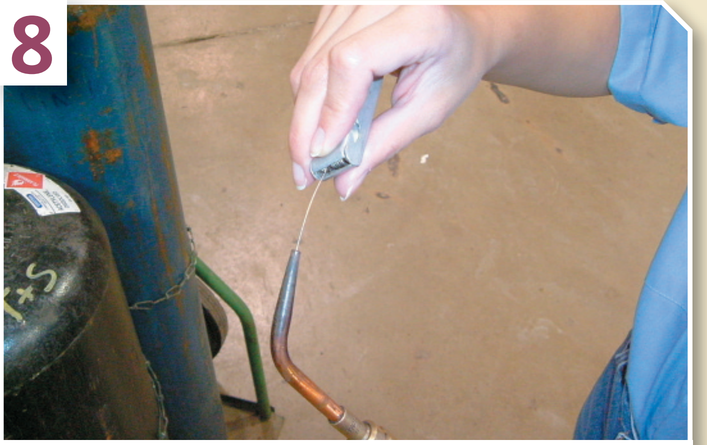
STEP BY STEP

7



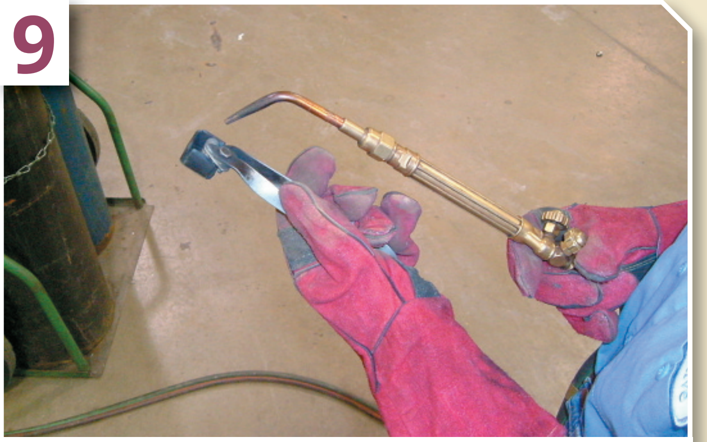
Open the acetylene valve on the torch handle ¼ turn and adjust acetylene gas pressure to 7 PSI. Close the acetylene valve on the torch handle

8



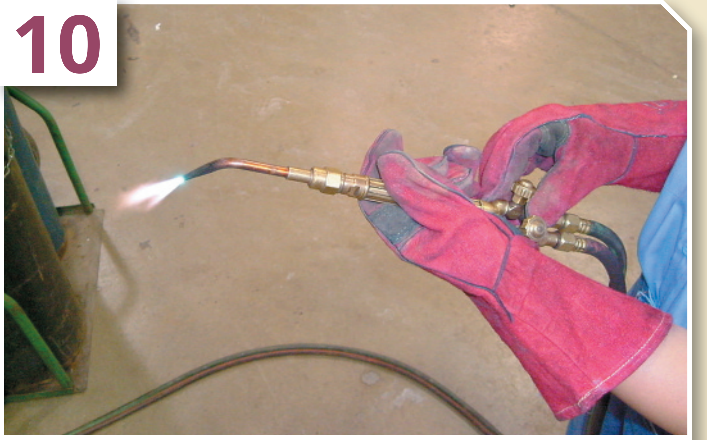
Open the oxygen valve on the torch handle ¼ turn and use an appropriate size tip cleaner to clean the tip orifice. Finish by closing the oxygen valve.

9



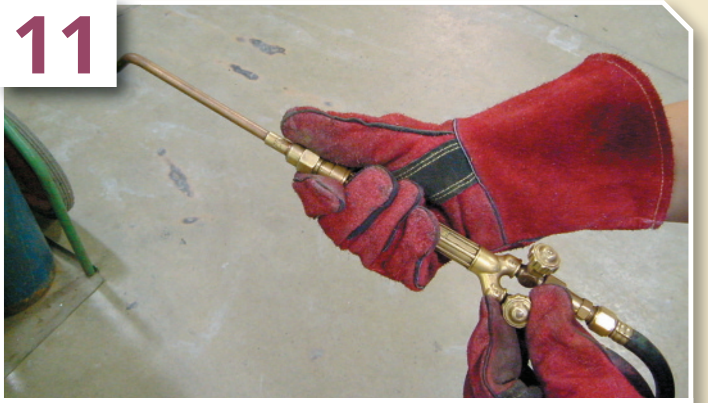
Put on leather gloves and open the acetylene valve on the torch handle ¼ turn Use a flint striker to ignite the acetylene gas exiting the torch tip.

10



Adjust the acetylene valve until the base of the flame just touches the torch tip. Slowly open the oxygen valve on the torch handle and adjust for a neutral flame (blue cone is well-defined).

11



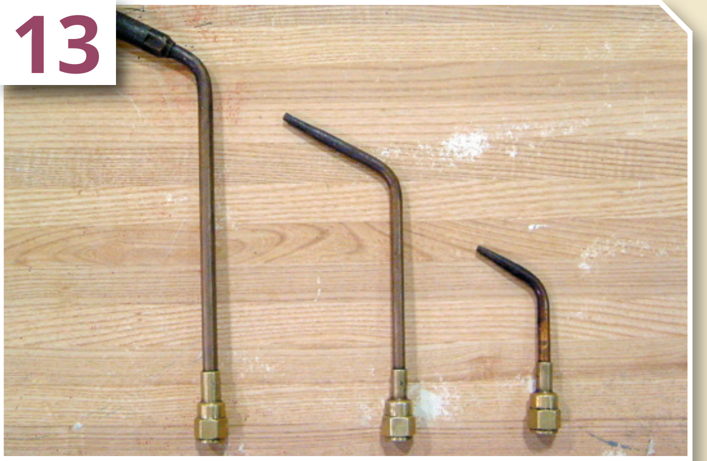
Once work is complete, extinguish the flame by quickly closing the acetylene valve on the torch handle. Be prepared to hear a loud “pop” when the flame goes out. Close the oxygen valve on the torch handle.

12

Close the valves on both tanks and turn the regulator handles counterclockwise until they no longer contact the internal springs. Open the gas valves briefly on the torch handle to release gas pressure from the hoses. Close the gas valves on the torch handle and put away the torch assembly.

HEATING METAL

13



Heating attachments include ordinary heating tips, middle and right and a “rosebud” (left). Ordinary heating tips work fine for most purposes, but occasionally the rosebud is utilized when a great deal of heat is needed

14

Note that while acetylene tank pressures are relatively low, the oxygen tank can be filled to over 2,000 PSI. This can represent a serious hazard if precautions are not taken. Be absolutely certain that the tanks are chained properly to the cart before attempting to move them!

15

Any time heating or cutting operations are being performed, be sure that any flammables have been removed from the immediate area. A fire blanket may be placed over floor drains or other objects to prevent fires. A fire extinguisher should be on hand in case of an emergency.

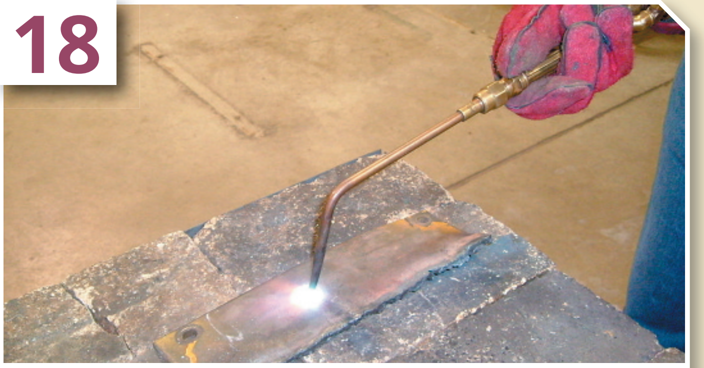
16

Be sure to wear appropriate personal protective equipment during heating and cutting operations.

17

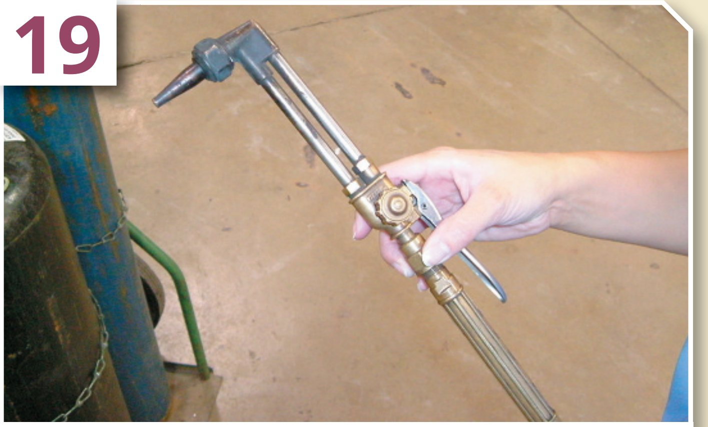
Note that heating operations should be performed over steel or firebrick. Never heat or cut steel close to concrete, as it could cause the concrete to explode.

18



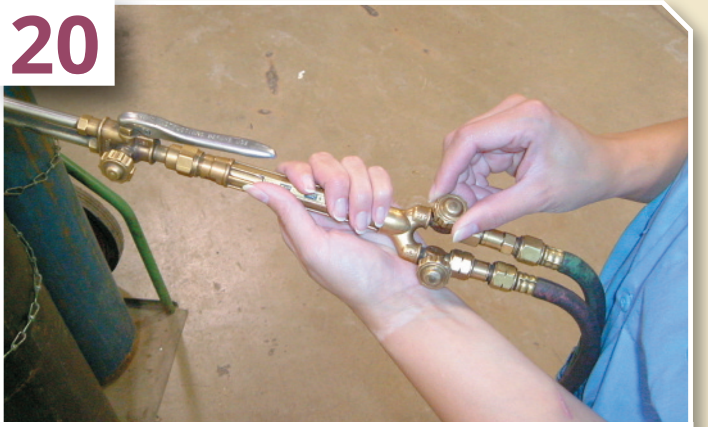
When heating steel, move the torch in a circular pattern to prevent melting of the metal. Don’t hold the torch too close to the work as this will cause a “snapping” or “backfire” that can extinguish the flame.

19



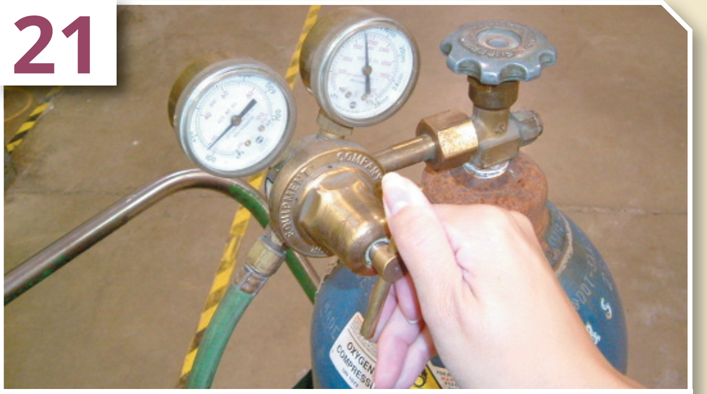
Affix the cutting attachment to the torch handle. Note that the cutting attachment has a cutting handle and a separate oxygen valve.

20



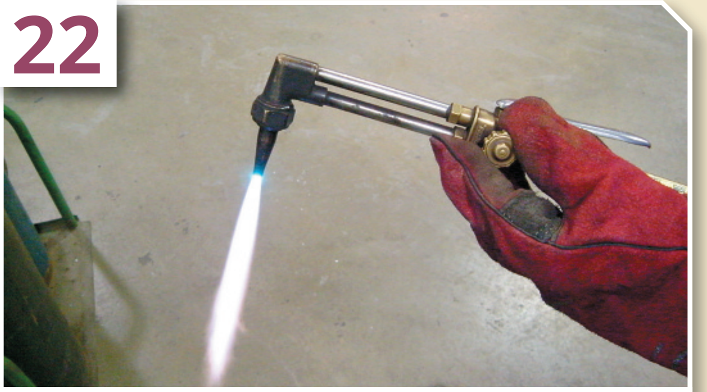
Fully open the oxygen valve on the torch handle. Oxygen flow will now be controlled with the valve on the cutting attachment.

21



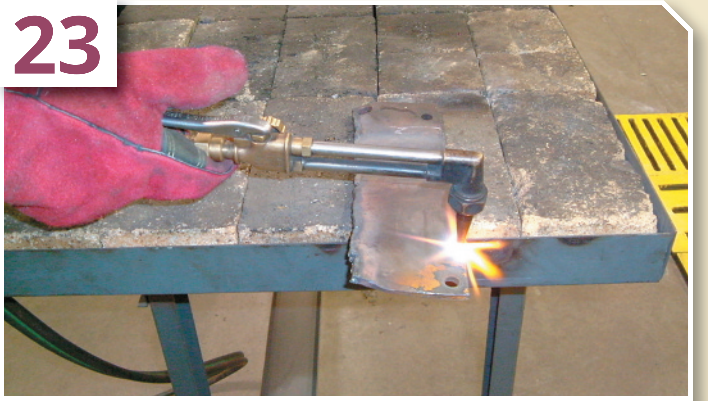
Oxygen gas pressure should be adjusted to 30 PSI whenever using the cutting attachment. Acetylene pressure is kept at 7 PSI.

22



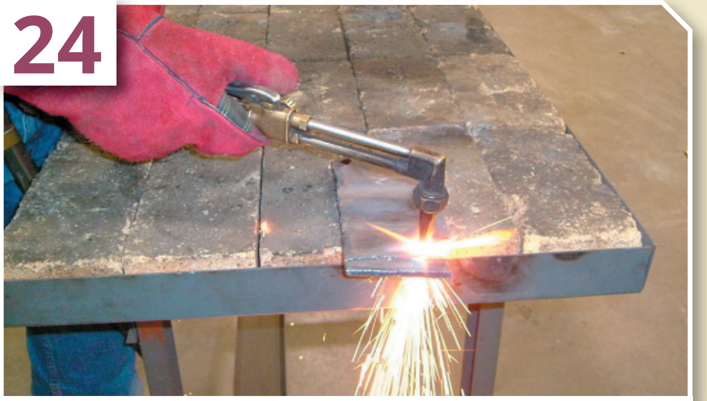
Open the acetylene valve on the torch handle ¼ turn and light the torch. Adjust the flame until its base just touches the cutting tip. Slowly open the oxygen valve on the cutting attachment and adjust the flame until the blue cone is well-defined.

23



Direct the flame onto a thin spot or sharp edge of the metal to be cut. This will build the heat quicker in order to get the cut started.

24



When the metal glows red, depress the cutting handle and move the torch to advance the cut. You will need to move the torch faster when cutting thinner pieces of steel. On thicker pieces, point the cutting tip into the direction of the cut.

CHAPTER QUIZ

1. An engine makes a clicking like sound like a lifter, and all of the hydraulic lifters were recently replaced. Which of these could be the cause?
   - **a.** Leaking catalytic converter
   - **b.** Cracked exhaust manifold
   - **c.** Cracked intake manifold
   - **d.** Clogged exhaust pipe
2. A technician uses a vacuum gauge to check for an exhaust restriction. The vacuum is read at idle and then at 2,000 RPM. What result would indicate an exhaust restriction?
   - **a.** Vacuum increases
   - **b.** Vacuum falls
   - **c.** Reading stays the same
   - **d.** Reading climbs very slowly
3. Two technicians are discussing the small hole in the muffler. Technician A says that some mufflers have a small hole located in the rear at the bottom to drain out condensed water. Technician B says that you need to periodically drain the water using a vacuum pump. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
4. Which of these is the biggest concern when you find a rust hole in an exhaust system?
   - **a.** Exhaust gases escaping
   - **b.** High noise level
   - **c.** High exhaust emissions
   - **d.** Failing state inspection
5. On which vehicle label would you find emission calibration codes?
   - **a.** VIN (vehicle identification number)
   - **b.** Parts and accessories label
   - **c.** VECI (vehicle emissions control information) label
   - **d.** VSC (vehicle safety certification) label
6. A technician is in the process of removing the bolts on a catalytic converter. Technician A says that you should be using a six-point socket. Technician B says water pump pliers (slip joint) should be used at slip-joint connections to hold the pipe. Which technician is correct?
   - **a.** Technician A only
   - **b.** Technician B only
   - **c.** Both Technicians A and B
   - **d.** Neither Technician A nor B
7. Exhaust hangers are used to ___________ vibrations in the exhaust system.
   - **a.** focus
   - **b.** isolate
   - **c.** increase
   - **d.** remove
8. Which of these fabrication processes results in an exhaust pipe that duplicates the original pipe?
   - **a.** Pattern bending
   - **b.** Custom bending
   - **c.** Program card bending
   - **d.** Wire bending
9. Which of these welding methods uses carbon dioxide or argon gas?
   - **a.** MIG welding
   - **b.** Oxy-acetylene welding
   - **c.** Arc-welding
   - **d.** All of these
10. Which type of flame is used for soldering?
    - **a.** Neutral
    - **b.** Oxidizing

GLOSSARY

A-arm Another name for a control arm because it often looks like the letter A.

Aboveground storage tank (AGST) A type of oil storage.

Absolute humidity Absolute humidity is the measurement of the weight of the water vapor in a given volume of air.

Abutments All braking force is transferred through the caliper to the mount. The places where the caliper contacts the caliper mount are called the abutments, reaction pads, or ways.

AC coupling A signal that passes the AC signal component to the meter, but blocks the DC component. Useful to observe an AC signal that is normally riding on a DC signal; for example, charging ripple.

AC ripple voltage While it is normal to measure some AC voltage from an alternator, excessive AC voltage, called AC ripple, is undesirable and indicates a fault with the rectifier diodes or stator windings inside the alternator.

AC/DC clamp-on DMM A type of meter that has a clamp that is placed around the wire to measure current.

Accelerator pedal position (APP) sensor A sensor that is used to monitor the position and rate of change of the accelerator pedal.

Accumulator A temporary location for fluid under pressure.

Acid materials Pure water is neutral; on the pH scale, water is pH 7. Caustic materials have pH numbers from 8 through 14. The higher the number, the stronger the alkaline action will be. Acid materials have pH numbers from 1 through 6. The lower the number, the stronger the acid action will be.

Acoustic vehicle alerting system (AVAS) Electric vehicles and most hybrid electric vehicles emit a sound through a speaker in the front at low speeds to warn pedestrians that a moving vehicle is nearby. This system is called acoustic vehicle alerting system (AVAS).

Active balancing Active balancing is achieved when energy is drawn from the most charged cell and transferred to the least charged cells, usually through DC–DC converters.

Active grille shutters (AGS) Plastic shutters that open or close to control the airflow going under the hood. The primary function of the active grille shutters is to reduce the aerodynamic drag of the vehicle when closed.

Active mode When the TPM sensor inside the tire detects that the vehicle is traveling above 20 mph (32 km/h), the sensor transmits once every minute.

Active wheel speed sensors Active wheel speed sensors are called active because they require outside electrical power to operate.

Actuator cylinder The cylinder used to transfer movement from the clutch master cylinder to the throw-out bearing to apply or release the clutch.

Actuator An electromechanical device that performs mechanical movement as commanded by a controller.

Adaptive cruise control An adaptive cruise control, often called radar cruise control, uses radar, lasers, cameras, or a combination of sensors, to keep a constant distance from the vehicle ahead.

Adaptive Front Lighting Systems (AFS) Active front headlight system. A name for the system that causes the headlights to turn when cornering.

Additive package A number of chemicals that will help each other can be used for each of the additive requirements. The balanced additives are called an additive package.

Adhesive-lined heat shrink tubing A type of heat shrink tubing that shrinks to one-third of its original diameter and has glue inside.

Adjustable pedals Adjustable pedals, also called electric adjustable pedals (EAP), place the brake pedal and the accelerator pedal on movable brackets that are motor operated.

Adjustable wrench A wrench that has a moveable jaw to allow it to fit many sizes of fasteners.

Adsorption By a process called adsorption, the fuel vapor molecules adhere to the carbon surface. This attaching force is not strong, so the system purges the vapor molecules quite simply by sending a fresh airflow through the charcoal.

Advanced Engagement (AE) Starter When energized, the pinion shifts forward by the starter solenoid and engages with the engine's ring gear/flywheel, and immediately spins.

Advisor A role played by a mentor.

Advocate A role played by a mentor.

Aerated Aerated means air mixed with the oil.

Afterblow Afterblow is a term used to describe the operation of the blower motor after the ignition has been turned off. The purpose of afterblow is to dry the evaporator to help prevent the formation of mold and mildew in the evaporator case.

After-blow module An electrical control that will run the HVAC blower after the vehicle has been shut off. Its purpose is to dry the evaporator fins.

Aftermarket parts Referring to repair parts produced by companies other than OEM.

Aftermarket parts Replacement parts that are not manufactured by the original vehicle manufacturer.

Aftermarket Jobber parts are not made by the original manufacturer of your vehicle. These parts are also called aftermarket parts. The aftermarket industry makes up about 80% of the parts used in vehicle repair.

AFV Alternative fuel vehicle.

Agitation Parts washers are often used in place of soaking tanks. This equipment can move parts back and forth through the cleaning solution or pumps the cleaning solution over the parts. This movement, called agitation.

AGM The acid used in an absorbed glass mat (AGM) battery is totally absorbed into the separator, making the battery leak proof and spill proof.

Air compressor A piece of shop equipment that uses an electric motor to power an air compressor, which is stored in a pressure tank for use in the shop.

Air doors A system that contains the HVAC plenum, ducts, and air doors is called the air management system, or air distribution system, and controls the airflow to the passenger compartment

Air drill An air drill is a drill that rotates faster than electric drills (up to 20,000 RPM). Air drills are commonly used in auto body work when many holes need to be drilled for plug welding.

Air filter An air filter filters dirt from the air before it enters the intake system of the engine.

Air inlet Air inlet door is used to select outside or inside air inlet.

Air management system The system of solenoids and valves that control the flow of air from the secondary air injection system.

Air pressure check An air pressure check uses air to apply clutches and/or bands to verify that components such as clutch packs perform correctly.

Air ratchet An air-operated hand tool that rotates a socket.

Air spring A rubber fabric air-filled bag used to replace a spring.

Air suspension A type of suspension that uses air springs instead of steel springs.

Airbag An inflatable fabric bag that deploys in the event of a collision that is server enough to cause personal injury.

Air-blow gun A handheld nozzle attached to a compressed air hose to apply air pressure to a component or device.

Air-fuel ratio sensor A term used to describe a wide-band oxygen sensor.

Air-fuel ratio The ratio of air to fuel in an intake charge as measured by weight.

Air-injection reaction (AIR) An AIR pump that pumps air in a secondary air-injection system.

Alemite fittings Grease fittings are also called Zerk fittings (named for Oscar U. Zerk) or Alemite fittings (named for the manufacturer of early grease fittings).

Alert mode Alert mode is triggered if a rapid change in inflation pressure is detected. In alert (or rapid mode), the tire inflation pressure is sent about every second (every 800 milliseconds on some sensors).

Algorithm A series of mathematical calculations used to make precise determinations.

Alkaline A substance with a pH of higher than 7.

Alternator An electric generator that produces alternating current; also called an *AC generator*.

Aluminum Aluminum was the last of the three materials to be used for automotive bearings. Automotive bearing aluminum has small quantities of tin and silicone alloyed with it. This makes a stronger but more expensive bearing than either babbitt or copper-lead alloy.

Always Be Charging (ABC) The saying that many owners of electric vehicle mention when discussing charging at home. Due to the vehicle itself needing to keep the systems functional and within a temperature range, many owners simply keep their EV connected to the charging station when at home.

AM Amplitude modulation.

Amber ABS warning lamp The dash warning lamp that lights if a fault in the antilock braking system (ABS) is detected.

Ambient air temperature sensor This sensor is usually located at the front of the vehicle behind the grille but in front of the radiator. The purpose of this sensor is to detect the temperature of the outside air. This sensor is commonly called the ambient air temperature sensor.

Ambient side electrode This electrode is exposed to outside (ambient) air and is the signal electrode, also called the reference electrode or ambient air electrode.

American National Standards Institute (ANSI) American National Standards Institute, an organization that publishes safety standards for safety glasses and other personal protective equipment.

American Petroleum Institute (API) The American Petroleum Institute gravity, or API gravity, is a measure of how heavy or light a petroleum liquid is compared to water. The American Petroleum Institute (API), working with the engine manufacturers and oil companies, has established an engine oil performance classification. Oils are tested and rated in production automotive engines. The oil container is printed with the API classification of the oil.

American Society for Testing Materials (ASTM) ASTM International, formerly known as American Society for Testing and Materials, is an international standards organization that develops and publishes voluntary consensus technical standards for a wide range of materials, products, systems, and services. The American Society for Testing Materials (ASTM) specifies the consistency of grease using a penetration test.

American wire gauge (AWG) A method used to measure wire diameter.

Ammeter An electrical test instrument used to measure amperes (unit of the amount of current flow).

Ampere hour A method used to rate battery capacity.

Ampere The unit of the amount of current flow. Named for André Ampère (1775–1836).

Ampere-turns The unit of measurement for electrical magnetic field strength.

Amplitude The difference between the highest and lowest level of a waveform.

Anaerobic sealers Anaerobic sealers cure in the absence of air. They are used as thread lockers (such as Loctite®), and they are used to seal rigid machined joints between cast parts.

Analog display An analog display uses a needle to show the values, such as engine RPM.

Analog-to-digital (AD) converter An electronic circuit that converts analog signals into digital signals that can then be used by a computer.

Anchor eyes One end of the web usually has a notch where the wheel cylinder touches the shoe, while the other end commonly has a flat or curved surface where the shoe meets an anchor or adjusting link. The upper ends of the webs on dual-servo brake shoes have semicircular cutouts called anchor eyes.

Anchor plate The support for the anchor pin on a drum brake backing plate.

Annulus gear The outer ring gear has teeth on the inside that mesh with the teeth of the planet pinion gears. The ring gear is also called the annulus gear or internal gear because the gear teeth are on the inside (rather than the outside) portion of the gear.

Anode The positive electrode; the electrode toward which electrons flow.

ANSI American National Standards Institute, an organization that publishes safety standards for safety glasses and other personal protective equipment.

Anti-dive A term used to describe the geometry of the suspension that controls the movement of the vehicle during braking. It is normal for a vehicle to nose-dive slightly during braking and is designed into most vehicles.

Antidrainback valve Many oil filters are equipped with an antidrainback valve that prevents oil from draining out of the filter when the engine is shut off.

Antifriction bearings Bearings that use steel balls or rollers to reduce friction.

Antiknock index (AKI) The octane rating posted on a gas pump, which is the average of the RON and MON octane ratings.

Antilock brake system (ABS) A system that is capable of pulsing the wheel brakes if lockup is detected to help the driver maintain control of the vehicle.

Antirattle clips Metal clips used to eliminate or dampen noise in a brake system.

Antiseize compound Lubrication of moving or sliding components prevents noise from being generated as the parts move over each other. Many vehicle manufacturers recommend Antiseize compound.

Anti-squat A term used to describe the geometry of the suspension that controls the movement of the vehicle body during acceleration. 100% anti-squat means that the body remains level during acceleration. Less than 100% indicates that the body ``squats down,” or lowers in the rear during acceleration.

API gravity The density or specific gravity of diesel fuel is measured in units of API gravity. API gravity is an arbitrary scale expressing the gravity or density of liquid petroleum products devised jointly by the American Petroleum Institute and the National Bureau of Standards.

Application cables The application cables use the force passed through the linkage to apply the rear-wheel brake assembly.

Application Programming Interface (API) A pass-through device or API serves as a connection point that makes all the hardware look the same, and allows the computer with the reprogramming software to communicate with the vehicles control module through the data link connector (DLC).

Apply devices Apply devices or holding devices are the mechanical or hydraulic assemblies that provide the force to hold or drive members of a planetary gear set.

Appointment Log The appointment log is created by the service consultant to record all the vehicles that are scheduled to come in on a particular day.

Appointment An arrangement to provide services at a particular place and time.

Apprentice program An apprentice program involves a beginning service technician working at a shop or dealership during the day and attending training classes in the evening. The key advantage to this type of program is that money is being earned due to full-time employment and getting on-the-job training (OJT) during the day.

Aqueous-based solutions Because of environmental concerns, most chemical cleaning is now performed using water-based solutions (also called aqueous-based solutions). Most aqueous-type chemicals are silicate–based and are mixed with water.

Arithmetic average roughness height (RA) The usual method of expressing surface finish is by the arithmetic average roughness height (RA), that is, the average of the distances of all peaks and valleys from the mean (average) line. Surface finish is measured using a machine with a diamond stylus.

Armature The rotating unit inside a DC generator or starter, consisting of a series of coils of insulating wire wound around a laminated iron core.

Arming sensor A sensor used in an air bag circuit that is most sensitive and completes the circuit first of two sensors that are needed to deploy an air bag.

Armor The fiber facing is protected around the combustion chamber with a metal armor (also called a fire ring).

Armored brake line Steel brake line that has wire wrapped around it to provide protection against stones and other debris.

Articulation test A test specified by some vehicle manufacturers that tests the amount of force necessary to move the inner tie rod end in the ball socket assembly. The usual specification for this test is greater than 1 lb. (.5 Kg.) and less than 6 lbs. (2.7 Kg.) of force.

Asbestos Asbestos is the term used to describe naturally occurring silicate minerals that consist of long fibers.

Assembly lube Lubricant that is designed to remain on the parts and not drip or run is called assembly lube.

Association des Constructeurs Européens d’ Automobiles (ACEA) The Association des Constructeurs Européens d’Automobiles (ACEA) rates the oil according to specific criteria.

ASTM American Society for Testing Materials.

Asymmetrical If the specifications vary, the camshaft is called asymmetrical.

Atmospheric pressure Pressure exerted by the atmosphere on all things based on the weight of the air (14.7 pounds per square inch at sea level).

Auto link A type of automotive fuse.

Automated manual transmission (AMT) Another term used to describe a dual-clutch automatic transmission/transaxle.

Automatic air-conditioning system A system that uses sensors and actuators to maintain a preset temperature inside a vehicle.

Automatic climate control system A system that controls the temperature and blower motor operation to control the climate inside the vehicle automatically depending on the preset temperature selected by the driver or passenger.

Automatic emergency braking (AEB) Automatic emergency braking automatically applies the brakes to avoid a collision.

Automatic headlights Automatic headlights automatically turn on the headlights when the light sensor detects low ambient light level.

Automatic level control (ALC) The automatic level control (ALC) system automatically adjusts the rear height of the vehicle in response to changes in vehicle loading and unloading.

Automatic reversal systems (ARS) Public Law 110-189, also known as the Cameron Gulbransen Kids Transportation Safety Act, mandated the use of power window automatic reversal systems (ARS). The automatic reversal system is designed to prevent windows from causing injury when they are closing.

Automatic shutdown (ASD) relay Many Chrysler group products use an automatic shutdown (ASD) relay to power the ignition coil. The ASD relay does not supply voltage to the coil unless the engine is cranking and the computer senses a crankshaft sensor signal.

Automatic temperature control (ATC) system Automatic air-conditioning systems are usually called automatic temperature control (ATC) systems.

Automatic transmission fluid (ATF) Fluid used in vehicles with self-shifting or automatic transmissions. automatic transmission fluid (ATF) is another important fluid that should be checked regularly.

Aviation tin snips Cutters designed to cut sheet metal.

Axial load A force in line (same axis) as the centerline of the bearing or shaft.

Axis All gear teeth lie parallel to the centerline, or axis, of the gear.

Axle ratio The gear ratio of the final drive (differential) is called the axle ratio.

Axle windup The movement of the rear axle on a rear-wheel-drive vehicle equipped with a leaf spring-type suspension during acceleration.

B20 A blend of 20% biodiesel with 80% petroleum diesel.

B5 A blend of 5% biodiesel with 95% petroleum diesel.

Babbitt Babbitt is the oldest automotive bearing material. Isaac Babbitt (1799–1862) first formulated this material in 1839. An excellent bearing material, it was originally made from a combination of lead, tin, and antimony.

Back clearance The space behind the ring is called the back clearance.

Back pressure The exhaust system’s resistance to flow. Measured in pounds per square inch (PSI).

Back pressure The exhaust system’s resistance to flow. Measured in pounds per square inch (psi).

Back spacing The distance between the back rim edge and the center section mounting pad of a wheel.

Back taper Back taper is an angle cut opposite to the chamfer so that spline or tooth narrows just behind the chamfered end.

Backfire A mistimed explosion in the cylinder. A backfire can take place with improper torch operation. The flame will go out with a loud snap or pop.

Backorder A backorder is for parts ordered from a supplier but not shipped due to them being out of stock.

Backup camera A camera mounts on the rear of the vehicle that is used to display what is behind a vehicle when the gear selector is placed in reverse.

Baffle A plate or shield used to direct the flow of a liquid or gas.

Balance valve In operation, the opening and closing of the exhaust port occurs many times per second. This sequence of events achieves a steady pressure as the valve balances both the spring pressure and the hydraulic pressure. Because of this action, this type of valve is sometimes called a balance valve.

Balancing bosses (pads) Many connecting rods are made with balancing bosses (pads) so that their weight can be adjusted to specifications.

Ball bearings An anti-friction bearing that uses steel balls between the inner and outer race to reduce friction.

Ball joints A ball and socket joint used in the front suspension to allow up and down and turn motion of the front wheel.

Ball socket assembly An inner tie rod end assembly that contains a ball and socket joint at the point where the assembly is threaded on to the end of the steering rack.

Bank The V-8 engine has four inline cylinders in each of the two blocks that are placed at a 90-degree angle to each other. Each group of four inline cylinders is called a bank.

Bar One bar is the pressure of the atmosphere at sea level, or about 14.7 PSI.

Barometric manifold absolute pressure (BMAP) sensor The barometric manifold absolute pressure (BMAP) sensor is actually a combination of a BARO and MAP sensor in the same housing.

Barometric pressure (BARO) sensor A sensor that measures both the barometric pressure and the absolute pressure in the intake manifold.

Barrel face ring A barrel face ring can replace the outer ring taper on some rings. Barrel faces are found on rectangular rings and on torsionally twisted rings

Barrier hoses A type of refrigerant hose that has a barrier material to precent the escape of the small molecules or refrigerant.

Base brakes Service brakes are the main driver-operated brakes of the vehicle. Service brakes are also called base brakes or foundation brakes.

Base The name for the section of a transistor that controls the current flow through the transistor.

Battery cables Cables that attach to the positive and negative terminals of the battery.

Battery control module (BCM) The battery control module (BCM) is responsible for controlling the operation of the high voltage battery based on the requests from the hybrid control module.

Battery Council International (BCI) Battery sizes are standardized by the Battery Council International (BCI).

Battery density Battery density refers to the amount of energy in kilowatt-hours (kWh) that a battery can store per kilo-gram of mass (kWh per kilograms) or volume (kWh per liter) of volume. The higher the number, the higher the energy density of the battery.

Battery electric vehicles (BEV) A battery electric vehicle (BEV), also called an electric vehicle (EV), uses a high-voltage battery pack to supply electrical energy to an electric motor(s) to propel the vehicle under all driving conditions.

Battery electrical drain test A test to determine if a component or circuit is draining the battery.

Battery Maintainer A battery maintainer is designed to hold the vehicle at a specific voltage throughout the duration of the repair.

Battery management system (BMS) The battery management system (BMS) is an electronic system that manages cells in a battery pack. The BMS monitors and controls the State of charge (SOC), State of health (SOH), State of function (SOF), Temperature and Load balancing/individual cell efficiency.

Bead The part of a tire that is made of wire that the body plies are wrapped around.

Beam-type torque wrench A type of wrench that displays the torque being applied to a fastener by the position of a deflective pointer and a scale, indicating the amount of torque.

Bearing crown The wall thickness of most bearings is largest in the center, called the bearing crown.

Bearing shell An engine bearing is called a bearing shell, which is a steel backing with a surface coating of bearing material. The steel provides support needed for the shaft load.

Bearing splitter A two-part steel device used between a bearing and a gear or other component, which is used to remove the bearing using a hydraulic press.

Bearingized A hard surface created inside a wheel cylinder or master cylinder by forcing a hardened steel ball through the bore.

Bedded-in Some manufacturers recommend that their replacement brake pads be bedded-in or burnished before returning the vehicle to the owner.

Bedplate S A bedplate is a structural member that attaches to the bottom of the block and supports the crankshaft. The oil pan is mounted under the bedplate, which in most cases is also part of the structure and support for the block assembly.

Beehive hold-down A type of hold-down spring used on drum brakes and shaped like a beehive.

Bell housing A bell-shape housing attached between the engine and the transmission.

Bellmouth When an open edge of a brake drum friction surface has a larger diameter than the closed edge, the drum is suffering from bellmouth distortion.

Belt Fabric or woven steel material over the body plies of a tire, and just under the tread area, to help keep the tread from squirming.

Bench grinder An electric motor with a grinding stone and/or wire brush attached at both ends of the armature and mounted on a bench.

Bench testing A test of a component such as a starter before being installed in the vehicle.

Bench vise A bench vise is used to hold components so that work can be performed on the unit.

Bend To shape and/or force into a curve or angle.

BEV Battery electric vehicle.

Bevel gear differential The bevel gear differential uses two bevel gears or spider gears attached to the output shaft of the transmission.

Bevel gear The teeth of a bevel gear are cut at an angle to the outside gear surface. Simple bevel gears have straight-cut teeth similar to those on a spur gear.

Bias voltage In electrical terms, bias is the voltage applied to a device or component to establish the reference point for operation.

Billet A billet crankshaft is machined from a solid piece of forged steel called a billet.

Biodiesel A renewable fuel manufactured from vegetable oils, animal fats, or recycled restaurant grease.

Bipolar transistor A type of transistor that has a base, emitter and collector.

BJI Abbreviation for ball-joint inclination.

Bleed holes In series flow systems, bleed holes or steam slits in the gasket, block, and head perform the function of letting out the steam.

Bleeder valve A threaded valve used to bleed air from a brake hydraulic system.

Blind spot monitor A blind spot monitor is an option that may include more than monitoring the front, rear and sides of the vehicle. It can include cross traffic alert, which can sound an alarm when backing out of a parking space when traffic is approaching from either side.

Block deck The cylinder head is fastened to the top surface of the block. This surface is called the block deck. The deck has a smooth surface to seal against the head gasket.

Block The foundation of any engine. All other parts are either directly or indirectly attached to the block of an engine.

Blocker ring In synchronized construction there are a number of design variations, all are similar and include a hub, a sliding sleeve, a blocker ring, (or stop ring or synchronizer ring), keys, and springs.

Blowby Blowby is the leakage of combustion gases past the rings and blows oil from the cylinder wall.

Bluetooth A short range wireless communication standard named after a Danish king that had a Bluetooth.

BNC connector Coaxial-type input connector. Named for its inventor, Neil Councilman.

Body control module (BCM) Many HVAC systems are controlled by the body control module (BCM).

Body ply A layer of cloth that gives a tire its strength.

Body The body of the vehicle is used to provide the support for the suspension and steering components as well as the powertrain.

Body-on-frame (BOF) vehicles A type of vehicle construction, often used with pickup trucks that use a separate frame and then the body is installed on top.

Bolt circle The diameter (in inches or millimeters) of a circle drawn through the center of the bolt holes in a wheel.

Bolts Most of the threaded fasteners used on vehicles are cap screws. They are called cap screws when they are threaded into a casting. Automotive service technicians usually refer to these fasteners as bolts.

Bonded linings Brake linings that are glued or bonded to the brake shoes.

Boost An increase in air pressure above atmospheric. Measured in pounds per square inch (psi).

Bore The inside diameter of the cylinder in an engine.

Bores The cylinder holes are called bores because they are made by a machining process called boring.

Bottom dead center (BDC) The lowest position in the cylinder that a piston can travel without reversing its direction.

Bound electrons electrons that are close to the nucleus of the atom.

Boundary lubrication When the oil film is thick enough to keep the surfaces from seizing, but can allow some contact to occur.

BOV Blow-off valve (BOV). Also called a dump valve or vent valve, the BOV features an adjustable spring design that keeps the valve closed until a sudden release of the throttle. The resulting pressure increase opens the valve and vents the pressurized air directly into the atmosphere.

Box-end wrench A double-ended tool with one end being like an open-end wrench or open-ended spanner, and the other end being like a box-end wrench or ring spanner. Both ends generally fit the same size of bolt. A box-end wrench is angled 15 degrees to allow it to clear nearby objects.

Boxer A type of engine design that is flat and has opposing cylinders. Called a boxer because the pistons on one side resemble a boxer during engine operation. Also called a *pancake engine.*

Braided ground straps Ground wires that are not insulated and braided to help increase flexibility and reduce RFI.

Brake assist system (BAS) Some vehicles are equipped with a brake assist system (BAS) that applies the brakes with maximum force if the system detects that the driver is making a panic stop.

Brake bleeding A process of removing air from the brake hydraulic system.

Brake block Brake pad material is pressed into a brake block before being heated to become a brake pad.

Brake fade A result of heat buildup. It is the reduction in braking force due to loss of friction between the brake shoes and the drum or between the disc brake pads and the rotor.

Brake fluid level sensor Since the late 1990s, master cylinders use a brake fluid level sensor or switch in the master cylinder reservoir. This sensor lights the red brake warning lamp (RBWL) on the dash if low brake fluid level is detected.

Brake fluid A non-petroleum-based fluid called polyglycol used in hydraulic brake systems.

Brake hardware kits Springs, clips, and other hardware items to replace the original items when the brake lining or pads are replaced.

Brake horsepower (bhp) The horsepower derived from a dynamometer is called brake horsepower (bhp). The horsepower is calculated from the torque readings at various engine speeds (in revolutions per minute or RPM). Horsepower is torque times RPM divided by 5252.

Brake pad The term used to describe the brake friction material used in disc brakes.

Brake pedal position (BPP) sensor An analog brake pedal position signal from the brake pedal-mounted brake pedal position (BPP) sensor. The BPP sensor outputs an analog signal, referenced to 5 volts, that increases or decreases with brake pedal depression.

Brake pipes Lines that carry brake fluid from the master cylinder to the wheel brakes.

Brake shoe holddowns Springs or clips used to hold brake shoes against the backing plate.

Brake shoe return springs While the return springs retract the brake shoes to their unapplied positions, the brake shoe holddowns keep the shoes securely against the support pads on the backing plate.

Brake shoes The part of the brake system upon which the brake lining is attached.

Brake tubing Pipes used to carry brake fluid from the master cylinder to the wheel brakes.

Brake Any device that is designed to slow or stop a mechanism or component.

Branches electrical parts of a parallel circuit.

Breaker bar (flex handle) A long-handled socket drive tool.

Breakout box (BOB) A piece of test equipment that installs between an electrical/electronic component, such as a controller, and the wiring harness.

Breather port Another name for the master cylinder replenishing port (rearward port).

Brinelling A type of mechanical failure used to describe a dent in metal such as what occurs when a shock load is applied to a bearing. Named after Johann A. Brinell, a Swedish engineer.

British thermal unit (BTU) The amount of heat required to raise 1 pound of water 1°F at sea level.

Bronze guides A type of replacement valve guide. Replacement valve guides can be installed to repair worn integral guides. Both cast-iron and bronze guides are available.

Brush-end housing The end of a starter or generator (alternator) where the brushes are located.

Brushes A copper or carbon conductor used to transfer electrical current from or to a revolving electrical part such as that used in an electrical motor or generator.

Bucket Overhead camshaft engines use several different types of valve opening designs. One type opens the valves directly with a bucket.

Bulb test A test to check the operation of certain circuits controlled by the ignition switch.

Bulkhead The panel between the engine compartment and the passenger compartment.

Bump cap A hat that is plastic and hard to protect the head from bumps.

Bump stop A rubber or urethane stop to limit upward suspension travel. Also called a strikeout bumper, suspension bumper, or compression bumper.

Burn kV The spark line voltage is called the burn kV.

Burnished Some manufacturers recommend that their replacement brake pads be bedded-in or burnished before returning the vehicle to the owner.

BUS A term used to describe a communication network.

Bypass valve (Engine Oil and Filters) Either the engine or the filter is provided with a bypass valve that will allow the oil to go around the filter element.

Bypass valve (Turbocharging and Supercharging) Many factory installed superchargers are equipped with a bypass valve that allows intake air to flow directly into the intake manifold, bypassing the supercharger. The computer controls the bypass valve actuator.

Bypass Allows a small part of the coolant to circulate within the engine during warm-up. It is a small passage that leads from the engine side of the thermostat to the inlet side of the water pump. It allows some coolant to bypass the thermostat even when the thermostat is open.

CA Cranking amperes. A battery rating.

Cabin filter A filter located in the air intake of the HVAC system.

Cage The support for rollers or ball bearings.

California Air Resources Board (CARB) A state of California agency which regulates the air quality standards for the state.

Calorie (c) Heat is measured in calories (c). The calorie is a metric unit that expresses the amount of heat needed to raise the temperature of one gram of water one degree Celsius.

Cam chucking Cam chucking is the movement of the camshaft lengthwise in the engine during operation.

Cam follower Overhead camshaft engines use several different types of valve opening designs. One type opens the valves directly with a bucket. One type uses a cam follower, also called a finger follower, that provides an opening ratio similar to that of a rocker arm.

Cam ground Aluminum pistons expand when they get hot. A method of expansion control was devised using a cam ground piston skirt.

Camber roll The camber angle of the front wheels due to caster.

Camber The inward or outward tilt of the wheels from true vertical as viewed from the front or rear of the vehicle. Positive camber means the top of the wheel is out from center of the vehicle more than the bottom of the wheel.

Cam-in-block design An engine where the crankshaft is located in the block rather than in the cylinder head.

Cam-in-block There are two basic areas where the camshaft can be located in an engine. In the engine block. This design is called the cam-in-block design. The camshaft is supported in the block by camshaft bearings and driven by the crankshaft with a gear or sprocket and chain drive. Engines with the cam located in the block are called pushrod or overhead valve (OHV) engines.

Campaign A recall where vehicle owners are contacted to return a vehicle to a dealer for corrective action.

Camshaft bearings There are two basic areas where the camshaft can be located in an engine. In the engine block. This design is called the cam-in-block design. The camshaft is supported in the block by camshaft bearings and driven by the crankshaft with a gear or sprocket and chain drive. Engines with the cam located in the block are called pushrod or overhead valve (OHV) engines.

Camshaft duration Camshaft duration is the number of degrees of crankshaft (not camshaft) rotation for which a valve is lifted off the seat.

Camshaft position (CMP) sensor To get a spark out of an ignition coil, the primary coil circuit must be turned on and off. This primary circuit current is controlled by a transistor (electronic switch) inside the ignition module or (igniter).There are various ways crankshaft position (CKP) sensors or camshaft position (CMP) sensors are used.

Camshaft A shaft with lobes which open valves when being rotated through a chain, belt, or gear from the crankshaft.

CAN Controller Area Network, a type of serial data transmission.

Cap screws Most of the threaded fasteners used on vehicles are cap screws. They are called cap screws when they are threaded into a casting. Automotive service technicians usually refer to these fasteners as bolts.

Capacitance Electrical capacitance is a term used to measure or describe how much charge can be stored in a capacitor (condenser) for a given voltage potential difference. Capacitance is measured in farads or smaller increments of farads such as microfarads.

Capillary action The movement of a liquid through tiny openings or small tubes.

Captive O-ring Captive O-rings use a larger-diameter cross section than standard O-rings placed positively in a shallow groove.

Carbohydrates All life-forms are able to collect, store, and use energy from their environment. In carbon-based biology, the basic energy storage compounds are in carbohydrates, where the carbon atoms are linked by single bonds into a chain.

Carbon dioxide (CO2) Carbon dioxide (CO2) is a colorless and odorless gas which is naturally occurring chemical compound.

Carbon footprint The carbon footprint includes energy-related emissions from human activities, including heat, light, power, refrigeration, and all transport-related emissions from vehicles, freight, and distribution.

Carbon monoxide (CO) A colorless, odorless, and highly poisonous gas. It is formed by the incomplete combustion of gasoline.

Carbon Most of the energy used in the world has been generated by burning organic fuel that contains carbon (abbreviated C). An economy that uses only carbon-based fuels is often referred to as a carbon-based society. Carbon is formed from materials that were once alive on the earth

Carburizing flame A reduction of an oxygen and fuel flame which leads to an excess of fuel (acetylene) gas that results in a carburizing flame. The high acetylene or carburizing flame is the one most commonly used by automotive technicians to heat parts or to solder. More acetylene is burned than oxygen, so the inner cone has a feather. The inner cone is also white. The envelope around the carburizing flame has the same look as the neutral flame and the temperature is about 5700° F (3154° C).

Carcass ply Plies of fabric in a tire that covers the entire tire from bead to bead.

Cardan joints A term used to describe U-joints, also called crossyoke joints. Cardan is named for a sixteenth-century Italian mathematician who worked with objects that moved freely in any direction.

Case hardening To improve wear resistance, some manufacturers harden the crankshaft journals. Methods used to harden the crankshaft journals includes Case hardening, where only the outer portion of the surface is hardened. Case hardening involves heating the crankshaft and adding carbon to the journals, where it causes the outer surface to become harder than the rest of the crankshaft.

Caster The forward or backward tilt of an imaginary line drawn through the steering axis as viewed from the side of the vehicle. Positive caster is where an imaginary line would contact the road surface in front of the contact path of the tire.

Cast-iron guides A type of replacement valve guide. Replacement valve guides can be installed to repair worn integral guides. Both cast-iron and bronze guides are available.

CAT III An electrical measurement equipment rating created by the International Electrotechnical Commission (IEC). CAT III indicates the lowest level of instrument protection that should be in place when performing electrical measurements on hybrid or electric vehicles.

Catalysts A catalyst is a chemical that helps start a chemical reaction, but does not enter into the chemical reaction.

Catalytic converter An emission control device located in the exhaust system that changes HC and CO into harmless H2O and CO2. If a three-way catalyst NOx is also divided into harmless separate nitrogen (N2) and Oxygen (O2).

Catalytic cracking Breaking hydrocarbon chains using heat in the presence of a catalyst.

Category three (CAT III) See CAT III.

Cathode ray tube (CRT) An analog scope uses a cathode ray tube (CRT), similar to some television screens, to display voltage patterns.

Cathode The negative electrode.

Caustic material Caustic materials have pH numbers from 8 through 14. The higher the number, the stronger the caustic action will be.

Caustic materials pH value, measured on a scale from 1 to 14, indicates the amount of chemical activity in the soap. Pure water is neutral; on the pH scale, water is pH 7. Caustic materials have pH numbers from 8 through 14. The higher the number, the stronger the alkaline action will be.

Cavitate Cavitation occurs when the pump tries to pull oil faster than it can flow from the pan to the pickup. When it cannot get enough oil, it will pull air. This puts air pockets or cavities in the oil stream. A pump is cavitating when it is pulling air or vapors.

CBV Compressor bypass valve (CBV). This type of relief valve routes the pressurized air to the inlet side of the turbocharger for reuse and is quiet during operation.

CCA Cold Cranking Amps. A rating of a battery tested at zero degrees F.

Cells A group of negative and positive plates to form a cell capable of producing 2.1 volts.

Celsius (centigrade) The Celsius scale was devised by taking the freezing point and the boiling point of water and dividing it into 100 equal parts.

CEMF Counter electromotive force.

Center bolt A bolt used to hold the leaves of a leaf spring together in the center. Also called a*centering pin.*

Center link The center part of a parallelogram-type steering linkage.

Center section The section of a wheel that attaches to the hub. Also called the spider.

Center support bearing A bearing used to support the center of a long drive shaft on a rear-wheel-drive vehicle. Also called a *steady bearing.*

Center take-off rack A type of rack-and-pinion steering gear that attaches the tie rods to the center of the rack instead of at the ends of the rack.

Central processing unit A control unit (computer) that processes data from sensors and then applies actuators.

Centrifugal pump A rotodynamic pump that uses a rotating impeller to increase the velocity of a fluid.

Ceramic Brake pads and linings that use synthetic material, such as aramid fibers, instead of steel are usually referred to as: 1. non-asbestos 2. non-asbestos organic (NAO) and 3. non-asbestos synthetic (NAS). These friction materials are often called ceramic in the American aftermarket because they include ceramic fibers, which are usually potassium titanite.

Cerium Since the early 1990s, many converters also contain cerium, an element that can store oxygen. The purpose of the cerium is to provide oxygen to the oxidation bed of the converter when the exhaust is rich and lacks enough oxygen for proper oxidation.

Cetane number The cetane number for diesel fuel is the opposite of the octane number for gasoline. The cetane number is a measure of the ease with which the fuel can be ignited.

CFR Code of Federal Regulations.

Channel A term used to describe a wheel brake being controlled by the antilock brake system controller.

Chapman strut A MacPherson strut-type of suspension used at the rear of the vehicle.

Charge density The more air and fuel that can be packed in a cylinder, the greater the density of the air-fuel charge.

Charge Policy A store's policy that out outlines credit purchases, refunds, and invoicing.

Charging voltage test an electrical test using a voltmeter and an ammeter to test the condition of the charging circuit.

Chart A chart is used to represent data, such as numbers or specifications, along with another variable, such as model or year of vehicle.

Chassis The frame, suspension, steering and machinery of a motor vehicle.

Cheater bar A pipe or other object used to lengthen the handle of a ratchet or breaker bar. Not recommended to be used as the extra force can cause the socket or ratchet to break.

Check balls Check balls are used in the valve body to allow hydraulic circuits to share a common passage. The check balls in these valves are usually made of steel, but they can be nylon, rubber, or some composite material as well.

Check valve A check valve contains a spring-type metallic disc or reed that closes under exhaust back pressure. Check valves are located between the air manifold and the switching valve(s). If exhaust pressure exceeds injection pressure or if the air pump fails, the check valve spring closes the valve to prevent reverse exhaust flow.

Chill spots Hard spots on a brake rotor or brake drum.

Chisel A sharpened tool used with a hammer to separate two pieces of an assembly.

CHMSL Centrally High Mounted Stop Light; the third brake light.

Christmas tree clips Plastic clips used to hold interior panels in place. The end that goes into a hole in the steel door panel is tapered and looks like a Christmas tree.

Circuit breakers A mechanical unit that opens an electrical circuit in the event of excessive current flow.

Circuit A circuit is the path that electrons travel from a power source, through a resistance, and back to the power source.

Clamping diode A diode installed in a circuit with the cathode toward the positive. The diode becomes forwarded biased when the circuit is turned off thereby reducing the high voltage surge created by the current flowing through a coil.

Clamping force Clamping force is the amount of force exerted on a gasket.

Clamps Clamps are U-bolts that come in different sizes that correspond to the pipe diameter that secure the slip joint connections that are attached to some exhaust system components. Clamps may also be used to attach hangers in some applications.

Class 2 A type of BUS communication used in General Motors vehicles.

Claw poles The magnetic points of a generator (alternator) rotor.

Clean Air Act A government action in 1990 to improve air quality.

Clicker-type torque wrench A clicker-type torque wrench is first set to the specified torque and then it "clicks" when the set torque value has been reached.

Clock generator A crystal that determines the speed of computer circuits.

Clock time The time charged to complete a service procedure, which is determined by the actual time spent.

Clock-in A method of payment that technicians may use and is the actual time spent on the repair as a basis for payment. Being paid for the actual time spent is often called straight time or clock time.

Clockspring A flat ribbon of wire used under the steering wire to transfer airbag electrical signals. May also carry horn and steering wheel control circuits depending on make and model of vehicle.

Closed loop As soon as the oxygen sensor (O2S) is capable of supplying rich and lean signals, PCM adjustments can be made to fine-tune the correct air-fuel mixture. This checking and adjusting of the PCM is called closed-loop operation.

Cloud point Cloud point is the low-temperature point when the waxes present in most diesel fuels tend to form crystals that can clog the fuel filter.

Cluster gears All manual transmissions/transaxles use a countershaft (also called a lay shaft or cluster shaft) to provide the other set of gears necessary to achieve the changes in gear ratios. The gears on the countershaft are called cluster gears or counter gears

Cluster shaft All manual transmissions/transaxles use a countershaft (also called a lay shaft or cluster shaft) to provide the other set of gears necessary to achieve the changes in gear ratios. The gears on the countershaft are called cluster gears or counter gears

Clutch cooling flow solenoid (CCFS) The solenoid that controls hydraulic oil for cooling of clutches of a dual clutch automatic transmission.

Clutch disc A clutch assembly consists of a clutch disc that is splined to the input shaft of the transmission/transaxle. When the driver depresses the clutch pedal, a throw-out bearing (release bearing) is forced against the fingers of the pressure plate.

Clutch drum The pressure plate and clutch assembly components fit into either a clutch drum (retainer) or a machined bore in the transmission case.

Clutch fork A lever that is pulled or pushed by a cable or hydraulic actuator on one end and pushes on the release bearing on the other end.

Clutch pack The multiple-plate clutch consists of plates, a piston, drum (retainer), and snap ring. Hydraulic pressure acts upon the clutch piston which moves in the drum. The piston movement compresses the plates together to provide either a holding or driving function. When the pressure is released, the piston returns to an unapplied position via a return spring assembly. This entire assembly is commonly known as a clutch pack.

Clutch pedal position switch A clutch pedal position switch is used to signal the starter circuit that the clutch is disengaged which prevents starter operation unless the clutch pedal is depressed.

Clutch pressure cut (CPCUT) The safety valve that controls pressure-dumping in the hydraulic system in a dual clutch automatic transmission.

Clutch shift pressure solenoid Controls hydraulic pressure for odd clutch or shifting in a dual clutch automatic transmission.

Clutch Any device that is made to couple one mechanism with another to cause each to rotate at the same speed.

Coach A role played by a mentor.

Coast (or concave) side While decelerating, the drive pinion contacts the ring teeth on its coast, or concave side.

Coast-down stall When an engine stalls coming to a stop this called a coastdown stall.

Coefficient of friction A measure of the amount of friction usually measured from 0 to 1. A low number (0.3) indicates low friction and a high number (0.9) indicates high friction.

Coil spring clutch A coil spring style of pressure plate uses coil springs and three or four release levers. A coil-spring-style pressure plate is also called the lever style .

Coil springs Coil springs are made of special round spring steel wrapped in a helix shape.

Coil A coil provides the magnetic pull to a movable armature (arm).

Coil-on-plug (COP) ignition (also coil-byplug, coil-near-plug,coil-over-plug) COP ignition Coil-on-plug ignition. This term describes ignition systems where each spark plug has its own coil assembly mounted directly over top of it. Also known as coil-over-plug, coil-by-plug, or coil-near-plug ignition.

Cold chisel A type of chisel used to remove rivets or to break off fasteners.

Cold Filter Plugging Point Cold Filter Plugging Point (CFPP) is the lowest temperature at that a specified volume of diesel type of fuel can pass through a standardized filtration device in a specified time when cooled under certain conditions.

Cold solder joint A type of solder joint that was not heated to high enough temperature to create a good electrical connection. Often a dull gray appearance rather than shiny for a good solder connection.

Collapsible column A steering column which collapses in the event of a front impact to the vehicle to help prevent injury to the driver.

Collector The name of one section of a transistor.

Column-mounted electric power steering (C-EPS) Column mounted. Column-mounted electric power steering (C-EPS) has sensors and the assist motor located inside the vehicle so they are not exposed to the heat and outside elements as is the rack-mounted system.

Combination circuit Another name for a series-parallel electrical circuit.

Combination valve A valve used in the brake system that performs more than one function, such as a pressure differential switch, metering valve, and/or proportioning valve.

Combination wrench A wrench that is open ended at one end and has a box end at the other end.

Combo Charging System (CCS) The SAE Combo Charging System (CCS) is a DC Fast Charging (DCFC) connector standard used by BMW, Ford, GM, VW, and other vehicle makers.

Combustion chamber The space left within the cylinder when the piston is at the top of its combustion chamber.

Combustion The rapid burning of the air-fuel mixture in the engine cylinders, creating heat and pressure.

Comfort zone The temperature range where humans feel comfortable, usually between 68°F and 78°F (20°C and 26°C).

Commission pay Income to a service technician determined by the number of hours that a flat-rate manual states in the time it should take multiplied by the hourly rate of the technician.

Communication The exchanging of information from one person to another. Communication may be verbal, non-verbal, or written.

Commutator segments The ends of the copper armature windings are soldered to commutator segments. The electrical current that passes through the field coils is then passed to the commutator of the armature by brushes that can move over the segments of the rotating armature.

Commutator-end housing The end of a starter motor that contains the commutator and brushes. Also called the brush end housing.

Compacted graphite iron (CGI) Compacted graphite iron (CGI) has increased strength, ductility, toughness, and stiffness compared to gray iron. If no magnesium is added, the iron will form gray iron when cooled, with the graphite present in flake form. If a very small amount of magnesium is added, more and more of the sulfur and oxygen form in the molten solution, and the shape of the graphite begins to change to compacted graphite forms. It has higher strength, stiffness, and toughness than gray iron.

Companion cylinder The cylinder that fires at the same time in a wastespark- type ignition system.

Companion flange The part that attaches to the driveshaft at the differential assembly.

Compensating port The port located in the master cylinder that allows excess fluid to return to the reservoir. See also vent port.

Complete circuit A type of electrical circuit that has continuity and current would flow if connected to power and ground.

Component identification (CID) The global (generic) data is used by most state emission programs. Global OBD-II displays often use hexadecimal numbers. Hexadecimal coding is also used to identify tests (test identification [TID] and component identification [CID]).

Composite camshaft Composite camshafts use a lightweight tubular shaft with hardened steel lobes press-fitted over the shaft.

Composite headlights A type of headlights that uses a separate, replaceable bulb.

Composite leaf spring A leaf spring made from a composite material, which usually includes fiberglass and epoxy resin.

Composite rotors Composite rotors use a steel center section with a cast-iron wear surface. These composite rotors are lighter in weight than conventional cast-iron rotors.

Compound circuit Another name for a series-parallel electrical circuit.

Comprehensive component monitor (CCM) Comprehensive component monitor (CCM). This monitor watches the sensors and actuators in the OBD-II system. Sensor values are constantly compared with known-good values stored in the PCM's memory.

Compressed natural gas (CNG) Another alternative fuel that is often used in fleet vehicles is compressed natural gas (CNG), and vehicles using this fuel are often referred to as natural gas vehicles (NGVs).

Compression ratio (CR) The ratio of the volume in the engine cylinder with the piston at bottom dead center (BDC) to the volume at top dead center (TDC).

Compression rings Piston rings are classified into two types,.one type is two compression rings, located toward the top of the piston'

Compression spring A spring which is part of a starter drive that acts on the starter pinion gear.

Compression test Can be used to test the condition of valves and piston rings.

Compressor speed sensor The air conditioning (A/C) compressor speed sensor, also called a lock or belt lock sensor, is used so the ECM will know if the compressor is running, and by comparing the compressor and engine speed signals, the ECM can determine if the compressor clutch or drive belt is slipping excessively.

Concentric clutch A clutch design where both plates share the same vertical plane provides a shorter assembly.

Concentric Perfectly round the relationship of two round parts on the same center.

Condenser An A/C system component located in front of the radiator in most vehicles that removes heat from the refrigerant and causes it to change from a gas to a liquid.

Conduction Conduction is the process of the heat traveling from a hotter part to a colder part of the same object or by direct contact.

Conductor A material that conducts electricity and heat. A metal that contains fewer than four electrons in its atom's outer shell.

Cone (inner ring) The inner race of a wheel bearing. Also a tapered metal cone with a hole in the center used to center a hubless brake drum or rotor on a brake lathe.

Conformability The ability of bearing materials to creep or flow slightly to match shaft variations is called conformability

Conicity A fault in a tire that causes it to be shaped like a cone and causes a pull.

Connecting rod bearing journal The crankshaft changes the up-and-down (reciprocating) motion of the pistons into rotary motion. The connecting rod is connected to a part of the crankshaft called a crank throw, crankpin, or connecting rod bearing journal.

Connecting rod Any rod connecting two moving parts in a mechanism such as piston which is attached to a crankshaft with a connecting rod.

Constant-mesh gear With constant-mesh gears, the shift linkage moves the 5-reverse synchronizer sleeve away from the fifth speed gear and toward the reverse speed gear when reverse is selected.

Constrained layer shims (CLS) Many original equipment brake pads use constrained layer shims (CLS) on the back of the brake pads. These shims are constructed with dampening material between two layers of steel.

Constructeurs Européens d' Automobiles (ACEA) Association des Constructeurs European d'Automobiles represents most of the Western European automobile and heavy-duty truck market. The organization uses different engines for testing than those used by API and SAE, and the requirements necessary to meet the ACEA standards are different yet generally correspond with most API ratings.

Continuity Instrument setup to check wiring, circuits, connectors, or switches for breaks (open circuit) or short circuits (closed circuit).

Continuously variable transmission (CVT) A transmission that uses two variable-width pulleys and a belt to change ratios from the lowest to the highest in a continuous, stepless manner instead of a group of fixed ratios.

Control arms A suspension link that connects a knuckle or wheel flange to the body or frame of the vehicle.

Control cables Control cables attach to the parking brake pedal, lever, or handle inside the vehicle.

Control module An electronic device used to control the operation of activities.

Controller A term that is usually used to refer to a computer or an electronic control unit (ECU).

Convection The movement of heat from the friction surface of a brake drum or rotor to the cooler part of the drum or rotor.

Conventional theory The theory that electricity flows from positive (+) to negative (−).

Coolant recovery system When the system cools, the pressure in the cooling system is reduced and a partial vacuum forms. This pulls the coolant from the plastic container back into the cooling system, keeping the system full.

Coolant The liquid mixture in the engine cooling system.

Cooling fins Heat is transferred through the tube wall and soldered joint to cooling fins. The fins are exposed to the air that flows through the radiator, which removes heat from the radiator and carries it away.

Cooling jacket Cylinders are surrounded by cooling passages. These coolant passages around the cylinders are often called the cooling jacket.

Cooling load The removal of heat to provide a comfortable environment.

Cooperative education Cooperative education programs are formal programs of study at a high school or college where the student attends classes at the school, and also works at a local shop or dealership.

Copper Copper is a soft metal with very high thermal and electrical conductivity and is used in most brake lining/pads.

Copper-lead alloy Copper-lead alloy is a stronger and more expensive bearing material than babbitt. It is used for intermediate- and high-speed applications. Tin, in small quantities, is often alloyed with the copper-lead bearings. This bearing material is most easily damaged by corrosion from acid accumulation in the engine oil. Also known as Trimetal.

Core charge An amount of money paid when a rebuildable part is purchased and refunded when the worn or defective part is returned to the parts store.

Core plugs Openings in the block are plugged with core plugs. Core plugs are also called freeze plugs or frost plugs.

Core tubes Are made from 0.0045 to 0.012 inch (0.1 to 0.3 mm) sheet brass or aluminum, using the thinnest possible materials for each application. The metal is rolled into round tubes and the joints are sealed with a locking seam.

Corrected torque This is a calculated number determined by the actual torque multiplied by the correction factor. There are subtle differences between each of the testing standards. The result after the correction factor has been applied is called corrected torque.

Correction factor A correction factor is a value that is multiplied to the data values so that engine performance can be compared, regardless of weather conditions.

Corrosion resistance By-products of combustion form acids in the oil. The bearings' ability to resist attack from these acids is called corrosion resistance.

Cotter pins A soft metal pin that is used to keep parts from loosening.

Coulomb A measurement of electrons. A coulomb is 6.28 x 101 (6.28 billion billion) electrons.

Counselor A Counselor is concerned about, but not trained to offer advice on personal life decisions.

Counter electromotive force (CEMF) A voltage produced by a rotating coil such as a starter motor where the armature is being moved through a magnetic field.

Counter gears All manual transmissions/transaxles use a countershaft (also called a lay shaft or cluster shaft) to provide the other set of gears necessary to achieve the changes in gear ratios. The gears on the countershaft are called cluster gears or counter gears

Countershaft All manual transmissions/transaxles use a countershaft (also called a lay shaft or cluster shaft) to provide the other set of gears necessary to achieve the changes in gear ratios. The gears on the countershaft are called cluster gears or counter gears

Counterweights Crankshafts are balanced by counterweights, which are cast, forged, or machined as part of the crankshaft. A crankshaft that has counterweights on both sides of each connecting rod journal is called fully counterweighted.

Country of origin The first number of the vehicle identification number (VIN), which identifies where the vehicle was assembled.

Coupling phase When the speed ratio is 90° or more, fluid flow in the torque converter is mostly rotary flow and the angle of flow from turbine to stator increases. This is called the coupling phase.

Courtesy lights General term used to describe all interior lights.

Cow Catcher A large spring seat used on many General Motors MacPherson strut units. If the coil spring breaks, the cow catcher is designed to prevent one end of the spring from moving outward and cutting a tire.

CPA Connector Position Assurance. A clip used to help hold the two parts of electrical connector together.

CPU Central Processor Unit.

Cracking A refinery process in which hydrocarbons with high boiling points are broken into hydrocarbons with low boiling points.

Cradle A structural support for the engine and transaxle on a front-wheel-drive vehicle.

Crank throw The crankshaft changes the up-and-down (reciprocating) motion of the pistons into rotary motion. The connecting rod is connected to a part of the crankshaft called a crank throw, crankpin, or connecting rod bearing journal.

Cranking vacuum test Measuring the amount of manifold vacuum during cranking is a quick and easy test to determine if the piston rings and valves are properly sealing.

Crankpin The crankshaft changes the up-and-down (reciprocating) motion of the pistons into rotary motion. The connecting rod is connected to a part of the crankshaft called a crank throw, crankpin, or connecting rod bearing journal.

Crankpins The rod bearing journals, also called crankpins, are offset from the centerline of the crank.

Crankshaft centerline The connecting rods and their bearings are attached to a bearing journal on the crank throw. The crank throw is offset from the crankshaft centerline. The distance between the centerline of the connecting rod bearing journal and the centerline of the crankshaft main bearing journal determines the stroke of the engine.

Crankshaft Position (CKP) sensor To get a spark out of an ignition coil, the primary coil circuit must be turned on and off. This primary circuit current is controlled by a transistor (electronic switch) inside the ignition module or (igniter).There are various ways crankshaft position (CKP) sensors or camshaft position (CMP) sensors are used.

Crankshaft Any shaft driven by a crank.

Creep Slight movement of the vehicle when the engine is at idle speed and the brakes are released is called creep.

Creeper A small platform mounted on short casters designed for a service technician to lie down and maneuver under a vehicle.

Crest The outside diameter of a bolt measured across the threads.

Crimp-and-seal connectors A type of electrical connector that has glue inside which provides a weather-proof seal after it is heated.

Critical thinking The process of analyzing and evaluating information and making a conclusion is called critical thinking.

Crosshatch finish The hone is stroked up and down in the cylinder as it rotates to produce a crosshatch finish on the cylinder wall which aides in proper ring break-in

Cross-steer linkage A type of steering linkage commonly used on light and medium trucks.

Cross-traffic alert A driver alert system that sounds an alarm when backing out of a parking space and traffic is approaching from either side.

Crowfoot socket A type of socket that slips onto the side of the bolt or nut. Used where direct access from the top is restricted.

Crown The tooth root is the depression lying between two teeth, and the crown is the very top of each tooth.

Cruise control A system that maintains the desired vehicle speed. Also called speed control.

Crush When the bearing is installed, each end of the bearing shell is slightly above the parting surface. When the bearing cap is tightened, the ends of the two bearing shells touch and are forced together. This force is called bearing crush. Crush holds the bearing in place and keeps the bearing from turning when the engine runs.

Cubic feet per minute (cfm) The cfm rating is the volume a vacuum pump can pump.

Cup (outer ring) Rubber seals that have a lip that forces outward when pressure is applied.

Cup design A design of an oxygen sensor that uses a shape like a cup or thimble.

Cuppy tire wear Scalloped tire wear usually on the inside or outside edges caused by defective or worn shock absorbers or other faults in the suspension system.

Cushion spring In the space between the friction surfaces of a clutch disc which is a wavy spring steel material.

Custom bending Used in exhaust system fabrication when there is no program card or existing pipe. Applications for which custom may be necessary include installing other than the original.

Customer pay (CP) Customer pay (CP) means that the customer will be paying for the service work at a dealership rather than the warranty.

Customer satisfaction survey A customer satisfaction survey is a study of a person's perceived satisfaction with a product or service. A completed survey provides answers for a list of questions that a company has concerning their products or service.

Customer Satisfaction Customer satisfaction is defined as the customer's overall feeling of satisfaction with an interaction with the store. Customer satisfaction recognizes the difference between customer expectations and customer perceptions. Satisfaction may develop quickly or may be refined over time.

CV joint boot The covering over a constant velocity joint made from rubber, thermoplastic, or urethane.

Cycle A cycle is a complete series of events that continually repeats. Most automobile engines use a four-stroke cycle.

Cylinder head temperature (CHT) Some vehicles are equipped with cylinder head temperature (CHT) sensors.

Cylinder leakage test A test that involves injecting air under pressure into the cylinders one at a time. The amount and location of any escaping air helps the technician determine the condition of the engine. The air is injected into the cylinder through a cylinder leakage gauge into the spark plug hole.

Cylinder A piston chamber in a internal combustion engine.

Damper drive A compressor-drive pulley with dampers/cushions to remove pulsations and no clutch.

Darlington pair Two transistors electrically connected to form an amplifier. This permits a very small current flow to control a large current flow. Named for Sidney Darlington, a physicist at Bell Laboratories from 1929 to 1971.

Data link connector (DLC) A multi-pin diagnostic connection port for vehicles used to interface a scan tool with control modules.

Daytime running lights (DRLs) Lights that are located in the front of the vehicle and come on whenever the ignition is on. In some vehicles, the vehicle has to be moving before they come on. Used as a safety device on many vehicles and required in many countries such as Canada since 1990.

DC coupling A signal transmission that passes both AC and DC signal components to the meter. (Also see AC coupling.)

DCFC (DC Fast Charge) Level 3 chargers are often called a DCFC (DC Fast Charge) or DC Quick Charge (DCQC).

Dead-blow hammer A type of hammer that has lead shot (small pellets) inside a steel housing, which is then covered with a plastic covering. Used to apply a blunt force to an object.

Deceleration sensors A sensor mounted to the body frame of a vehicle that detects and measures the deceleration of the vehicle. Used to control the activation of the airbags and vehicle stability systems.

Decibel (dB) A unit of the magnitude of sound.

Decimal point Decimals are used to represent fractions of a unit by using a dot called a decimal point to indicate that the number is a decimal.

Decking the block The block deck must be resurfaced in a surfacing machine that can control the amount of metal removed when it is necessary to match the size of the combustion chambers. This procedure is called decking the block.

Deep cycling The full discharge and then the full recharge of a battery.

Default gear A default (or limp-in) gear is the forward speed that is used if there is a failure in the electronic or computer system. If neither solenoid is engaged, then either second or third gear is actuated, depending on the exact make and model of the transmission or transaxle.

Default position The actuator is a DC electric motor and is often called a servomotor. The throttle plate is held in a default position by a spring inside the throttle body assembly.

Degrees A degree is 1/360th of a circle.

Delta pressure feedback EGR (DPFE) sensor Most Fords use an EGR monitor test sensor called a delta pressure feedback EGR (DPFE) sensor. This sensor measures the pressure differential between two sides of a metered orifice positioned just below the EGR valve's exhaust side. Pressure between the orifice and the EGR valve decreases when the EGR opens because it becomes exposed to the lower pressure in the intake. The DPFE sensor recognizes this pressure drop, compares it to the relatively higher pressure on the exhaust side of the orifice, and signals the value of the pressure difference to the PCM.

Delta pressure method Changing inflation pressure (usually requires lowering the inflation pressure by 5 to 10 PSI). This method is called the delta pressure method. The term delta refers to a change and is named for the Greek letter delta (Δ).

Delta winding A type of stator winding where all three coils are connected in a triangle shape. Named for the triangle-shape Greek capital letter.

Demand delivery system (DDS) Given the experience with both ERFS and MRFS, a need was recognized to develop new returnless technologies that could combine the speed control and constant injector pressure attributes of ERFS together with the cost savings, simplicity, and reliability of MRFS. This new technology also needed to address pulsation dampening/hammering and fuel transient response. Therefore, the demand delivery system (DDS) technology was developed.

Department of Transportation (DOT) The statutes pertaining to automotive brake systems are part of the Federal Motor Vehicle Safety Standards (FMVSS) established by the United States Department of Transportation (DOT).

Desiccant An ingredient, such as silica gel used to remove moisture from air. Used in electronic systems that uses air shocks or springs.

Despiking diode Another name of clamping diode.

Destination charging Hotels and motels often provide charging stations known as destination charging. Hotels are adding chargers to their properties to help attract EV drivers traveling on long trips.

Detonation A violent explosion in the combustion chamber created by uncontrolled burning of the air-fuel mixture; often causes a loud, audible knock. Also known as *spark knock* or *ping*.

DEX-COOL DEX-COOL, developed by Havoline, is just one brand of OAT coolant, which has been used in General Motors vehicles since 1996. DEX-COOL uses ethylhexanoic acid (2-EH) as a corrosive inhibitor. 2-EH is prone to damage plastics, such as Nylon 6.6 used in intake manifold gaskets and radiators

Diagnostic executive On OBD-II systems, the powertrain control module (PCM) incorporates a special segment of software. On Ford and GM systems, this software is called the diagnostic executive.

Diagnostic trouble codes (DTC) An alphanumeric or numeric sequence indicating a fault in a vehicle operating system. Each sequence corresponds to a specific malfunction.

Diagonal pliers Pliers designed to cut wire and to remove cotter keys. Also called *side cuts* or *dike pliers*.

Diagram A diagram is a graphic design that explains or shows the arrangement of parts.

Die grinder A handheld air-operated tool used with a grinding stone or a wire brush.

Die A die is used to cut threads on round rods or studs.

Dielectric Insulating materials are commonly called a dielectric. These substances are a poor conductors of electricity and can include air, mica, ceramic, glass, paper, plastic, or any similar nonconductive materials.

Diesel exhaust fluid (DEF) Urea also called Adblue used in some diesel engines' exhaust system to reduce emissions.

Diesel exhaust particulate filter (DPF) Diesel exhaust particulate filters (DPFs) are used in all light-duty diesel vehicles, since 2007, to meet the exhaust emissions standards.

Diesel oxidation catalyst (DOC) Diesel oxidation catalysts (DOC) are used in all light-duty diesel engines, since 2007. They consist of a flow-through honeycomb-style substrate structure that is wash coated with a layer of catalyst materials, similar to those used in a gasoline engine catalytic converter.

Diesohol Standard #2 diesel fuel combined with up to 15% ethanol.

Diff An abbreviation or slang for differential.

Differential case The ring gear is attached to a differential case that also contains small beveled spider gears or pinion gears.

Differential pressure sensor (DPS) Differential pressure sensors are used to monitor the soot loading of a particulate filter. The DPF differential pressure sensor (DPS) has two pressure sample lines. One line is attached before the DPF and the other is located after the DPF

Digital computer A computer that uses on and off signals only. Uses an A to D converter to change analog signals to digital before processing.

Digital display A digital display uses numbers to indicate values, such as vehicle speed'

Digital EGR valve General Motors used a digital EGR valve design on some engines. Unlike vacuum-operated EGR valves, the digital EGR valve consists of three solenoids controlled by the powertrain control module (PCM). Each solenoid controls a different size orifice in the base–small, medium, and large.

Digital multimeter (DMM) A digital multimeter is capable of measuring electrical current, resistance, and voltage.

Digital storage oscilloscope (DSO) A digital scope takes samples of the signals that can be stopped or stored and is, therefore, called a digital storage oscilloscope, or DSO.

Diode An electrical device that allows current to flow in one direction only.

Dipstick The oil level indicator which is commonly called a dipstick.

Direct drive A drive train that rotates the output shaft at the same speed as the input shaft. A direct drive has a gear ratio of 1:1.

Direct injection (DI) In a direct injection (abbreviated DI) diesel engine, fuel is injected directly into the cylinder.

Direct shift gearbox (DSG) Another term used to describe a dual-clutch automatic transmission/transaxle.

Direct-drive electric power steering (D-EPS) The rack-mounted system has the assist motor attached to the rack and is often called a rack-and pinion electric power steering (R-EPS) system. Another design has the assist motor surrounding the rack and this style is called a direct-drive electric power steering (D-EPS) system.

Disc brakes A type of wheel brake that squeezes two brake pads on both sides of a rotor or disc.

Disc thickness variation (DTV) A variation in the thickness of the rotor, commonly called disc thickness variation (DTV) can cause brake pedal pulsation during braking.

Discharge air temperature (DAT) sensor The discharge air temperature (DAT) sensor is located at the outlet of the vents. The purpose of this sensor is to inform the controller of the actual temperature at the discharge ducts.

Discharge line The line that connects the compressor discharge port to the condenser.

Discharge stroke The compressor piston movement that pumps refrigerant out of the cylinder.

Discs (disks) Another name for brake rotors. Also spelled disks. See brake rotor.

Displacement The total volume displaced or swept by the cylinders in an internal combustion engine.

Distillation the process of purification through evaporation and then condensation of the desired liquid.

Distortion The act of twisting or altering something out of its true, natural, or original state. The head should be checked in five planes. Checking the cylinder head gasket surface with a precision straightedge in five planes checks the head for warpage, distortion, bend, and twist.

Division A specific segment of a waveform, as defined by the grid on the display.

DMM Digital multimeter. A digital multimeter is capable of measuring electrical current, resistance, and voltage.

Dog Tracking A term used to describe the condition where the rear wheels do not follow directly behind the front wheels. Named for way many species of dogs run with their rear paws offset toward one side so their rear paws will not hit their front paws while running.

Doping The adding of impurities to pure silicon or germanium to form either P or N type material.

DOT 3 Rating of the most commonly specified brake fluid.

DOT 4 A brake fluid rating for polyglycol.

DOT 5.1 The highest rated polyglycol brake fluid.

DOT 5 Silicone brake fluid rating.

DOT tire code The Department of Transportation tire code. The first two letters identify the manufacturer and location. The last three or four numbers are the build date code.

Double flare A tubing end made such that the flare area has two wall thickness'.

Double knock If the piston pin is loose in the piston or in the connecting rod, it makes a sound while the engine is running. This is often described as a double knock.

Double overhead camshaft (DOHC) An engine design with two camshafts above each line of cylinders one for the exhaust valves and one for the intake valves.

Double roller chain In camshaft chain drives, if two chains are used side by side, this type of chain is called a double roller chain.

Double-Cardan joints Two Cardan-style U-joints are joined together.

Double-cut file A file that has two rows of teeth that cut at an opposite angle.

Double-trailing brake The least powerful non-servo drum brake is the double-trailing brake. This design has two trailing shoes and does not use any self energization. Both shoes have the same size and shaped linings that are applied with equal force by a pair of single-piston wheel cylinders.

DPDT Double-pole, double-throw switch.

DPST Double pole, single throw switch.

Drift A mild pull that does not cause a force on the steering wheel that the driver must counteract (also known as lead). Also refers to a tapered tool used to center a component in a bolt hole prior to installing the bolt.

Drive (or convex) side While a vehicle accelerates, the drive pinion contacts the ring teeth on its drive, or convex side.

Drive cycle A drive pattern is called a drive cycle. The drive cycle is different for each vehicle manufacturer but a universal drive cycle may work in many cases. in many cases, performing a universal drive cycle will reset most monitors in most vehicles.

Drive gear A drive gear is the source of power or rotation. Gear ratio is expressed as the number of rotations the drive gear must make in order to rotate the driven gear through one revolution.

Drive pinion gear The driveshaft applies torque to the drive pinion gear that meshes below the center line of a ring gear.

Drive plate The drive plate is attached to the compressor shaft. The drive plate is also called an armature or disc, and the pulley is also called a rotor.

Drive shaft A shaft that transfers engine torque from the output of the transmission to the rear axle (differential) assembly.

Drive size The size in fractions of an inch of the square drive for sockets.

Drive-by-wire Another term for electronic throttle control. See *ETC*.

Drive-end (DE) housing The end of a starter motor that has the drive pinion gear.

Drive-end housing 60 A starter consists of the main structural support called the field housing, one end of which is called a commutator-end (or brush-end) housing and the other end a drive-end housing. The drive-end housing contains the drive pinion gear, which meshes with the engine flywheel gear teeth to start the engine.

Driveline angles The angles of the driveshaft at the front and rear, which are equal, plus or minus 0.5 degrees.

Driven gear A driven gear is turned by the drive gear.

Driver selector switch The driver selector switch is a two- or three-mode switch, usually located in the center console, and is an input to the suspension control module.

Driveshaft runout A measurement of the amount a driveshaft is from perfectly round when rotated.

Driveshaft Driveshaft is the term used by the Society of Automotive Engineers (SAE) to describe the shaft between the transmission and the rear axle assembly on a rear-wheel-drive vehicle. General Motors and some other manufacturers use the term propeller shaft or prop shaft to describe this same part. The SAE term will be used throughout this textbook.

Drum brakes A type of wheel brake that uses expanding brake shoes inside a brake drum.

Dry bulb temperature Dry bulb temperature is the temperature of a room where the thermometer is shielded from moisture.

Dry cylinder sleeve The cast-iron cylinder sleeves are either cast into the aluminum block during manufacturing or pressed into the aluminum block. These sleeves are not in contact with the coolant passages and are called dry cylinder sleeves.

Dry park test A test of steering and/or suspension components. With the wheels in the straight ahead position and the vehicle on flat level ground, have an assistant turn the steering wheel while looking and touching all steering and suspension components looking for any looseness.

Dry sump In a dry sump system, the oil pan is shallow and the oil is pumped into a remote reservoir. In this reservoir, the oil is cooled and any trapped air is allowed to escape before being pumped back to the engine. A dry sump system uses an externally mounted oil reservoir.

Dual cell A design of a wide-band oxygen sensor that uses two cells.

Dual inline pins (DIP) A type of electronic chip that has two parallel lines of pins.

Dual overhead camshaft (DOHC) An engine design with two camshafts above each line of cylinders one for the exhaust valves and one for the intake valves.

Dual-diaphragm vacuum booster Dual-diaphragm or tandem-diaphragm vacuum boost are designed to increase the total area without increasing the physical diameter of the booster.

Dual-position actuator A dual-position actuator is able to move either open or closed. An example of this type of actuator is the recirculation door, which can be either open or closed.

Dual-servo brake A drum brake design where the primary (forward facing) brake shoe exerts force against the secondary (rearward facing) brake shoe during braking while the vehicle is traveling forward.

Dual-stage airbags Airbags that can deploy either with minimum force or full force or both together based on the information sent to the airbag controller regarding the forces involved in the collision.

Dual-zone Dual-zone air distribution allows the driver and passenger to select different temperature settings.

Ductile iron Ductile iron is used as a piston ring material in some automotive engines, which is very flexible and can be twisted without breaking.

Dump valve Blow-off valve (BOV). Also called a dump valve or vent valve, the BOV features an adjustable spring design that keeps the valve closed until a sudden release of the throttle. The resulting pressure increase opens the valve and vents the pressurized air directly into the atmosphere.

Duo-Servo Brand name of a Bendix dual-servo drum brake.

Durometer The hardness rating of rubber products named for an instrument used to measure hardness that was developed about 1890.

Duty cycle Refers to the percentage of on-time of the signal during one complete cycle.

DVOM Digital volt-ohm-milliammeter.

Dwell section Dwell is the amount of time that the current is charging the coil from the transistor-on point to the transistor-off point.

Dwell The amount of time, recorded on a dwell meter in degrees, that voltage passes through a closed switch.

Dye-penetrant testing Dye-penetrant testing is often used on pistons and other parts constructed of aluminum or other nonmagnetic material.

Dynamic compression test A running compression test, also called a dynamic compression test, is done with the engine running rather than during engine cranking as is done in a regular compression test.

Dynamic rear proportioning (DRP) Electronic brake proportioning (EBP) in the ABS is accomplished by monitoring brake switch input and front- and rear-wheel speeds, and reducing pressure to the rear brakes as needed using the ABS solenoids when there is a difference in wheel deceleration rates.

Dynamic seals Seals used between two surfaces where there is movement.

Dynamic voltage Voltage measured with the circuit energized and current flowing through the circuit.

Dynamometer (dyno or dyn) A dynamometer (often abbreviated as dyno or dyn) places a load on the engine and measures the amount of twisting force the engine crankshaft places against the load.

E10 A fuel blend of 10% ethanol and 90% gasoline.

E2PROM Electronically erasable programmable read only memory. A type of memory that can be electronically erased and reprogrammed.

E85 A fuel blend of 85% ethanol and 15% gasoline.

Easy out A tool used to extract a broken bolt.

ECA Electronic Control Module. The name used by Ford to describe the computer used to control spark and fuel on older model vehicles.

Eccentric cam An offset bolt and washer used to change an alignment angle.

Eccentric distortion A fault with brake drums where the geometric centerline of the drum is different from the centerline of the axle.

ECM Electronic control module on a vehicle.

ECU Electronic control unit on a vehicle.

Edge codes After January 1, 2014, all brake shoes and pads were required to have manufacturer's edge codes.

EDR Event data recorder. The hardware and software used to record vehicle information before, during and after an airbag deployment.

EEPROM Electronically Erasable Programmable Read Only Memory

EGR valve position (EVP) sensor A linear potentiometer on the top of the EGR valve stem indicates valve position to the PCM. This is called an EGR valve position (EVP) sensor.

EGR Exhaust gas recirculation. An emission control device to reduce NOx (oxides of nitrogen).

Elastic limit The limit of movement of brake shoes due to the metal not being able to return to its original dimensions.

Elastomer Another term for rubber.

Electric Adjustable Pedals (EAP) Adjustable pedals, also called electric adjustable pedals (EAP), place the brake pedal and the accelerator pedal on movable brackets that are motor operated.

Electric auxiliary pump An electric auxiliary pump is used to maintain fluid pressure in the transmission during internal combustion engine (ICE) idle stop.

Electric parking brake (EPB) Electric parking brake (EPB) systems are available using two different designs including the following: 1. A cable-pulling type that uses an electric motor to pull the parking brake cable rather than a mechanical handle or foot pedal and 2. A more advanced unit uses a computer-controlled motor attached to the brake caliper to activate it.

Electric power steering (EPS) A type of power steering that uses an electric motor to provide the steering assist.

Electric power-assisted steering (EPAS) A term commonly used to describe an electric power steering system.

Electric vehicle (EV) A term used to describe battery-powered vehicles.

Electrical Distribution System (EDS) The Electrical Distribution System (EDS) is to provide the electrical conduction path through the battery pack.

Electrical load Applying a load to a component such as a battery to measure its performance.

Electrical potential Another term to describe voltage.

Electricity The movement of free electrons from one atom to another.

Electrochemistry The term used to describe the chemical reaction that occurs inside a battery to produce electricity.

Electro-hydraulic power steering (EHPS) The electro-hydraulic power steering (EHPS) module controls the power steering motor, which has the function of providing hydraulic power to the brake booster and the steering gear

Electrolysis (Cooling System Operation and Diagnosis) Chemical decomposition produced by passing an electric current through a liquid. Electrolysis requires the use of an outside voltage source. The source is usually due to a poor electrical ground connection.

Electrolysis (Fule Cells and Advanced Technology) The chemical reaction in a fuel cell is the opposite of electrolysis. Electrolysis is the process in which electrical current is passed through water in order to break it into its components, hydrogen and oxygen. While energy is required to bring about electrolysis, this same energy can be retrieved by allowing hydrogen and oxygen to reunite in a fuel cell.

Electrolyte Any substance which, in solution, is separated into ions and is made capable of conducting an electric current. The acid solution of a lead-acid battery.

Electromagnet An electromagnet consists of a soft iron core surrounded by a coil of wire. Electrical current flowing through the coiled wire creates a magnetic field around the core.

Electromagnetic interference (EMI) An undesirable electronic signal. It is caused by a magnetic field building up and collapsing, creating unwanted electrical interference on a nearby circuit.

Electromagnetic parking sensors (EPS) Electromagnetic parking sensors (EPS) detect when a vehicle is moving slowly and towards an object

Electromotive force (EMF) The force (pressure) that can move electrons through a conductor.

Electron theory The theory that electricity flows from negative (−) to positive (+).

Electronic air control (EAC) The idle speed on newer vehicles is controlled by the electric throttle control (ETC) system.

Electronic brake control module (EBCM) The antilock brake system (ABS) control module. Also sontrols electronic suspension on some models.

Electronic brake proportioning The control of the rear brakes during heavy braking is controlled by the ABS controller instead of using a proportioning valve.

Electronic control unit (ECU) The ECM, which may also be referred to as the electronic control unit (ECU), is a small computer that receives input in the form of electrical signals from the sensors and switches and provides output electrical signals to the system actuators.

Electronic evaporator dryer (EED) An electrical control that will run the HVAC blower after the vehicle has been shut off. Its purpose is to dry the evaporator fins.

Electronic ignition system (EIS) Electronic ignition (EI) is the term specified by the SAE for an ignition system that does not use a distributor.

electronic leak detector Electronic leak detector meeting SAE J1628 is the most used method that experts and vehicle manufacturers recommend to find refrigerant leaks. Detector devices that are the most sensitive are capable of finding smaller leaks.

Electronic pressure control Electronic pressure control (EPC) is a type of electronic pressure regulation.

Electronic returnless fuel system (ERFS) A fuel delivery system that does not return fuel to the tank.

Electronic spark timing (EST) The computer controls spark timing advance.

Electronic stability control (ESC) Electronic stability control (ESC) is a system designed to help drivers to maintain control of their vehicles in situations where the vehicle is beginning to lose control.

Electronic throttle control (ETC) A system that moves the throttle plate using an electric motor instead of a mechanical linkage from the accelerator pedal.

Electronic vacuum regulator valve (EVRV) In some GM vehicles the PCM pulses the solenoid to control the vacuum that regulates the operation of the EGR valve. This called an electronic vacuum regulator valve (EVRV) by General Motors Corporation

Electronically controlled clutch assembly An electronically controlled clutch assembly is actuated by the vehicle's computer based on inputs from the ABS wheel speed sensors. If a wheel starts to spin, the computer can pulse the clutch on and off as necessary to control the amount of wheel slippage.

Electroplating The overplated bearing is a premium bearing. It is also the most expensive because the overplating layer, from 0.0005 to 0.001 inch (0.0125 to 0.025 mm) thick, is put on the bearing with an electroplating process.

Embeddability The bearings must be capable of embedding these particles into the bearing surface so that they will not score the shaft. To fully embed the particle, the bearing material gradually works across the particle, completely covering it. The bearing property that allows it to do this is called embeddability.

Embittered coolant This coolant has a small amount of a substance that makes it taste bitter and, therefore, not appealing to animals. The embittering agent used in ethylene glycol (EG) antifreeze is usually denatonium benzoate.

Emitter The name of one section of a transistor. The arrow used on a symbol for a transistor is on the emitter and the arrow points toward the negative section of the transistor.

Enable criteria A trip is defined as a key-on condition that contains the necessary conditions for a particular test to be performed, followed by a key-off. These conditions are called the enable criteria.

End cap An end cap is a rack or counter at the end of a store aisle used to display promotional or sale items. It is perceived to give a brand a competitive advantage.

Energy carrier Any medium that is utilized to store or transport energy. Hydrogen is an energy carrier because energy must be used to generate hydrogen gas that is used as a fuel.

Energy Capacity for performing work.

Engine coolant temperature (ECT) Computer-equipped vehicles use an engine coolant temperature (ECT) sensor. When the engine is cold, the fuel mixture must be richer to prevent stalling and engine stumble.

Engine fuel temperature (EFT) Some vehicles, such as many Ford vehicles that are equipped with an electronic returnless type of fuel injection, use an engine fuel temperature (EFT) sensor to give the PCM information regarding the temperature and, therefore, the density of the fuel.

Engine mapping A computer program that uses engine test data to determine the best fuel-air ratio and spark advance to use at each speed of the engine for best performance.

Engine stand A floor mounted-frame usually equipped with casters on which an engine can be attached and rotated.

Engine stop/start (ESS) With stop-start mechanism, the engine is stopped to reduce the fuel consumption when the vehicle is stopped at traffic signals or in stop and go traffic conditions.

Enhanced Flooded Batteries (EFB) Enhanced Flooded Battery (EFB) is a flooded battery (NOT an absorbed glass mat battery) that is optimized to work with stop/start vehicle systems.

Entrepreneur A person who owns a business.

EPA Environmental Protection Agency.

EPM Electrical Power Management. A General Motors term used to describe a charging system control sensor and the control of the generator(alternator) output based on the needs of the vehicle.

Equalizer A bracket used in a parking brake cable system to balance the force and transmit an equal amount to each rear brake assembly.

ESD Electrostatic discharge. Another term for ESD is static electricity.

Estimate The estimate is the suggested service cost to the customer which is determined by the service consultant.

Ethanol An octane enhancer added, at a rate of up to 10 percent, to gasoline; will increase the octane rating of the fuel by 2.5 to 3.0. Ethanol is a fuel oxygenate.

Ethics A set of principles that govern the conduct of an individual or group.

Ethyl alcohol Ethanol is also called ethyl alcohol or grain alcohol, because it is usually made from grain and is the type of alcohol found in alcoholic drinks, such as beer, wine, and distilled spirits like whiskey. Ethanol is composed of two carbon atoms and six hydrogen atoms with one added oxygen atom.

Ethylene glycol-based coolant Ethylene glycol is an organic compound used in antifreeze. All manufacturers recommend the use of ethylene glycol-based coolant.

EV Range The size or capacity of the battery pack used determines how far that the vehicle can travel without using the ICE, commonly called the EV range.

EV Electric vehicle. A term used to describe battery-powered vehicles.

EVA Abbreviation for electronic vibration analyzer. An EVA measures vibration frequency.

Evacuation To pump a vacuum into an A/C system to remove contaminated refrigerant and water.

Evaporative control (EVAP) system The purpose of the evaporative emission control system is to trap and hold gasoline vapors, also called volatile organic compounds (VOCs).

Evaporative cooling The process of cooling a surface using the evaporation of water.

Evaporator temperature (EVT) sensor A sensor used in automatic temperature control systems used to measure the temperature of the evaporator.

Exhaust gas recirculation (EGR) The process of passing a small, measured amount of exhaust gas back into the engine to reduce combustion temperatures and formation of NOx (oxides of nitrogen).

Exhaust manifold Exhaust manifolds collect exhaust gases from the cylinders and allows the exhaust gases to move to the exhaust pipe. The exhaust manifold bolts directly to the cylinder head and mates with the cylinder head exhaust ports.

Exhaust side electrode Exhaust-side electrode is exposed to the exhaust stream.

Exhaust valve A valve through which burned gases from a cylinder escape into the exhaust manifold. The exhaust valve opens, and the piston forces the residual burned gases out of the exhaust valve.

Expansion plugs Core holes left in the external block wall are machined and sealed with soft core plugs or expansion plugs (also called freeze plugs or Welsh plugs).

Exponentially weighted moving average (EWMA) monitor The exponentially weighted moving average (EWMA) monitor is a mathematical method used to determine performance.

Extended range electric vehicle.(EREV) A term used to describe an electric vehicle that has gasoline engine also that can be used to propel the vehicle.

Extension housing The rear of the transmission usually includes a separate casting called the extension housing.

Extension A socket wrench tool used between a ratchet or breaker bar and a socket.

External combustion engine An external combustion engine burns fuel outside of the engine itself, such as a steam engine.

External gears Spur and helical gears have gear teeth on their outside circumference and, for this reason, are called external gears. This type of gear is the most commonly used in manual transmissions and transaxles.

External trigger When using an oscilloscope connecting when the scope is to be triggered or started is connected to another circuit when the one being measured.

Eye Contact The action of looking directly into one another person's eyes. Eye contact is always important when we are communicating with others. In our culture, eye contact conveys sincerity and interest.

Eye wash station A water fountain designed to rinse the eyes with a large volume of water.

Fahrenheit A temperature scale developed by Gabriel Fahrenheit (1686-1736), a German physicist.

Fail safe position This partially open position, also called the neutral position or the fail safe position, is about 16% to 20% open.

False air Airflow sensors and mass airflow (MAF) sensors are designed to measure all the air entering the engine. If an air inlet hose was loose or had a hole, extra air could enter the engine without being measured. This extra air is often called false air.

False lean If an oxygen sensor reads low as a result of a factor besides a lean mixture, it is often called a false lean indication.

False rich An oxygen sensor reading that is high could be due to other things besides a rich air-fuel mixture. When the O2S reads high as a result of other factors besides a rich mixture, it is often called a false rich indication.

Farads A unit of capacitance named for Michael Faraday (1791–1867), an English physicist. A Farad is the capacity to store 1 coulomb of electrons at 1 volt of potential difference.

Fatigue life The length of time before fatigue will cause failure is called the fatigue life of the bearing.

Federal Motor Vehicle Safety Standards (FMVSS) The statutes pertaining to automotive brake systems are part of the Federal Motor Vehicle Safety Standards (FMVSS) established by the United States Department of Transportation (DOT).

Federal tax A payroll deduction.

Federal Test Procedure (FTP) In 1999, the EPA requested that states adopt OBD-II systems testing for 1996 and newer vehicles. The OBD-II system is designed to illuminate the MIL and store trouble codes any time a malfunction exists that causes the vehicle emissions to exceed 1 1/2 times the Federal Test Procedure (FTP) limits.

Feeler gauge A set of precision thickness steel blades used to measure a gap. Also called a *thickness gauge*.

FET Field effect transistor.

FFV Flex-fuel vehicle. Flex-fuel vehicles are capable of running on straight gasoline or gasoline/ethanol blends.

Fiber-reinforced matrix (FRM) Fiber-reinforced matrix (FRM) is used to strengthen cylinder walls in some Honda/Acura engines. FRM is a ceramic material similar to that used to construct the insulators of spark plugs. The lightweight material has excellent wear resistance and good heat transfer properties, making it ideal for use as a cylinder material. FRM inserts are placed in the mold and the engine block is cast over them.

FICA A payroll deduction (Federal Insurance Contribution Act, also known as Social Security).

Field coils Coils or wire wound around metal pole shoes to form the electromagnetic field inside an electric motor.

Field housing The part of a starter that supports the field coils.

Field poles The magnets used as field coils in a starter motor.

FIFO (first-in-first-out) Stock Rotation A type of stock rotation that places the first products into inventory to be purchased first and prevents older stock from getting an aged appearance.

Fifth gear In fifth gear, the shift linkage centers the 3–4 synchronizer sleeve and moves the fifth synchronizer sleeve toward the fifth speed gear. Note that on the T5 transmission the synchronizer assembly locks the fifth speed gear to the countershaft. The speed gear drives a fixed gear on the output shaft.

Files A metal smoothing tool.

Filler port A term sometimes used to identify the replenishing port (rear port) of a master cylinder.

Final drive assembly Most transaxles use speed gears and synchronizers on both the input and output shafts. The differential assembly is also called a final drive assembly.

Finger design A design of an oxygen sensor that uses a shape like a cup or thimble.

Finger follower Overhead camshaft engines use several different types of valve opening designs. One type opens the valves directly with a bucket. One type uses a cam follower, also called a finger follower, that provides an opening ratio similar to that of a rocker arm.

Fire blankets A fire-proof wool blanket used to cover a person who is on fire and smother the fire.

Fire ring The fiber facing is protected around the combustion chamber with a metal armor (also called a fire ring).

Firing line The leftmost vertical (upward) line is called the firing line. The height of the firing line should be between 5,000 and 15,000 volts (5 and 15 kV) with not more than a 3 kV difference between the highest and the lowest cylinder's firing line.

First gear In first gear, the shift linkage slides the 1–2 synchronizer sleeve rearward toward the first speed gear. The synchronizer assembly locks the speed gear to the output shaft.

First-class lever A type of lever where the fulcrum is between the weight and the force.

Fitting wrench A wrench that is used to remove the fitting holding a brake line or other line. Also called a *line wrench* or *flare-nut wrench*.

Five Basic Needs All customers have the five basic needs that need met when making a purchase: Service, Price, Quality, Action, and Appreciation.

Five-wheel alignment An alignment that not only includes the four wheels that are on the ground, but also includes the steering wheel.

Fixed brake caliper A type of disc brake caliper that has pistons on both sides of the rotor.

Fixed joint A type of CV joint used at the wheel end of the drive axle shaft.

Flare When the engine is warm and restarted, the idle speed should momentarily increase, then decrease to normal idle speed. This increase and then decrease in engine speed is often called an engine flare.

Flare-nut wrench A type of wrench used to remove brake lines.

Flashback A flashback is a rapid high-pressure flame in the hose, which can occur if there are not any check valves or the check valves fails to operate due to improper installation.

Flat rate Pay based on the amount of time published in a labor guide rather than using the actual amount of time spent on the repair.

Flathead A design where the valves are located in the engine block is called flathead design because the cylinder head simply covers the combustion chamber and includes a hole for the spark plug.

Flat-link type The silent chain type (also known as a flat-link type, or Morse type for its original manufacturer) operates quietly but tends to stretch with use. The metal links themselves do not "stretch" but, instead, the pin bushings at each joint wear, which causes the chain to become longer.

Flat-tip (straight blade) screwdriver A screwdriver used to remove and insert screws that have a single slot.

Flex Fuels The 15% gasoline in the E85 blend helps the engine start, especially in cold weather. Vehicles equipped with this capability are commonly referred to as alternative-fuel vehicles (AFVs), Flex Fuels, and flexible fuel vehicles (FFVs).

Flexible brake hoses Brake hoses between the body or frame of a vehicle and the caliper or axle.

Flexible coupling A part of the steering mechanism between the steering column and the steering gear or rack and pinion assembly. Also called a *rag joint* or *steering coupling disc.* The purpose of the flexible coupling is to keep noise vibration and harshness from being transmitted from the road and steering to the steering wheel.

Floating caliper A type of caliper used with disc brakes which moves slightly to assure equal pad pressure on both sides of the rotor.

Floating position The intermediate position between drive and coast, when neither the ring gear nor the pinion is driving each other, is called the "floating" position.

Flooded lead acid (FLA) Conventional batteries use a liquid electrolyte and are called flooded lead acid (FLA) batteries. In this design, vents are used to allow the gases (hydrogen and oxygen) to escape

Floor jack A hydraulic jack mounted on casters or steel wheels and used to lift a vehicle.

Flow Control Valve A valve that regulates and controls the flow of power steering pump hydraulic fluids to the steering gear or rack and pinion assembly. The flow control valve is usually part of the power steering pump assembly.

Flushing To clean a system by pumping a liquid through it.

Flux density The density of the magnetic lines of force around a magnet or other object.

Flux lines becomes. The magnetic lines of force, also called magnetic flux or flux lines, form a magnetic field. The terms magnetic field, lines of force, flux, and flux lines are used interchangeably.

Flying web The flange between the splayed crankpin journals is sometimes called a flying web.

FM Frequency modulation.

Fogging oil When assembling an engine, the parts should be coated with a light oil film to keep them from rusting. This type of oil is commonly referred to as fogging oil.

Footnote A footnote is used to provide additional information for multiple applications. The footnotes themselves are important and should be referenced systematically in order to define parts.

Force motors Force motors is a type of electronic pressure regulation.

Force The amount of effort measured in pounds or Newtons.

Forced induction systems Forced induction systems use an air pump to pack a denser air-fuel charge into the cylinders. Because the density of the air-fuel charge is greater, the following occurs.

Formal evaluation The mentor and/or service manager may or may not conduct a written evaluation on a regular basis. If a written evaluation is performed, this is called a formal evaluation.

Formed in place gaskets (FIPG) Formed in place gaskets (FIPG) are commonly used because they can be applied at the engine plant using a robot. The sealing material is extruded and placed onto the sealing surface, the two parts being sealed are placed together, and the fasteners tightened.

Forward bias Current flow in normal direction.

Foundation brakes Service brakes are the main driver-operated brakes of the vehicle. Service brakes are also called base brakes or foundation brakes.

Four-stroke cycle An internal combustion engine design where four strokes of the piston (two crankshaft revolutions) are required to complete one cycle of events. The four strokes include intake, compression, power, and exhaust.

Fourth gear In fourth gear, the shift linkage moves the 3–4 synchronizer sleeve forward, away from the third speed gear and toward the input shaft drive gear. The synchronizer assembly locks the input shaft drive gear to the output shaft.

Four-wheel alignment A wheel alignment that checks and adjusts, if necessary, the angles of all four wheels.

Fractional Specifications are often published in fractional or decimal degrees, or in degrees and minutes. There are 60 minutes (written as 60') in 1 degree.

Fractions A measurement in parts of an inch, such as ½, ¼, and 1/8.

Frames Frame construction usually consists of channel-shaped steel beams welded and/or fastened together.

Free electrons The outer electrons in an atom that has fewer than four electrons in it outer orbit.

Free rotators A type of valve retainer that allows the valve to be free to rotate when the valve is opening or closing.

Freewheeling engine A freewheeling engine is one that causes no internal damage if the camshaft drive belt breaks when the engine is running.

Freewheeling An engine that is designed not to have the pistons hitting the valves if the timing belt or chain breaks, is called freewheeling.

Freeze plugs Core holes left in the external block wall are machined and sealed with soft core plugs or expansion plugs (also called freeze plugs or Welsh plugs).

Freeze-frame A freeze-frame is a snapshot of important engine data at the time the DTC was set.

Frequency The number of times a waveform repeats in one second, measured in Hertz (Hz), frequency band.

Freshening A term used to describe the process of engine repair that usually includes only replacing the piston rings and rod bearings.

Fretting Expansion/contraction rate difference between the cast-iron head and the aluminum intake manifold can cause the intake manifold gasket to be damaged by the relative motion of the head and intake manifold. This type of failure is called fretting.

Fretting Fretting is a condition that can destroy intake manifold gaskets, caused by the unequal expansion and contraction of two different engine materials.

Front bearing retainer The throw-out bearing is often supported and rides on the transmission/transaxle front bearing retainer (also called the quill).

Front bearing retainers At the front of the transmission (toward the engine) is the front bearing retainer (sometimes called the quill) that supports the clutch throw-out (release) bearing and usually houses the front grease seal.

Front steer A construction design of a vehicle that places the steering gear and steering linkage in front of the center line of the front wheels. Also called forward steer.

Front/Rear split master cylinders Front/rear split master cylinders use two separate pressure-building sections. One section operates the front brakes and the other section operates the rear brakes on vehicles equipped with a front/rear-split system.

Frost plugs Openings in the block are plugged with core plugs. Core plugs are also called freeze plugs or frost plugs.

FTD Fischer-Tropsch diesel process. See *Fischer-Tropsch*.

Fuel cell An electrochemical device that converts the energy stored in hydrogen gas into electricity, water, and heat.

Fuel compensation sensor A sensor used in flex-fuel vehicles that provides information to the PCM on the ethanol content and temperature of the fuel as it is flowing through the fuel delivery system.

Fuel rail A port fuel-injection system uses a pipe or tubes to deliver fuel from the fuel line to the intended fuel injectors. This pipe or tube is called the fuel rail.

Fuel tank pressure (FTP) A fuel tank pressure (FTP) sensor then monitors the rate with which vacuum increases in the system. The monitor uses this information to determine the purge volume flow rate.

Fuel trim A computer function that adjusts fuel delivery during closed-loop operation to bring the air-fuel mixture to as close to 14.7:1 as possible.

Fuel-cell hybrid vehicle (FCHV) A fuel-cell vehicle (FCV) uses the fuel cell as its only source of power, whereas a fuel-cell hybrid vehicle (FCHV) also has an electrical storage device that can be used to power the vehicle.

Fuel-cell stack A collection of individual fuel cells, which are stacked end-to-end into one compact package.

Fuel-cell vehicle (FCV) A fuel-cell vehicle (FCV) uses the fuel cell as its only source of power, whereas a fuel-cell hybrid vehicle (FCHV) also has an electrical storage device that can be used to power the vehicle.

Fulcrum A pivot point of a lever.

Full frame A frame of a vehicle that extends the entire length and width of the vehicle.

Full round bearing Overhead camshaft bearings may be one of two sleeve-type bushings, depending on the design of the bearing supports. They are full round bearings or split-type (half-shell) bearings.

Full-floating A type of axle assembly where the weight of the vehicle is supported by the axle housing and not on the axle itself.

Fully counterweighted Crankshafts are balanced by counterweights, which are cast, forged, or machined as part of the crankshaft. A crankshaft that has counterweights on both sides of each connecting rod journal is called fully counterweighted.

Functionality OBD II also requires that inputs from powertrain components to the PCM be tested for rationality, and that outputs to powertrain components from the PCM be tested for functionality. Both inputs and outputs are to be checked electrically.

Fungible All gasoline is said to be fungible, meaning that it is capable of being interchanged because each grade is created to specification, so there is no reason to keep the different gasoline brands separated except for grade.

Fuse link A safety device used on a solvent washer which would melt and cause the lid to close in the event of a fire. A type of fuse used to control the maximum current in a circuit.

Fuses An electrical safety unit constructed of a fine tin conductor that will melt and open the electrical circuit if excessive current flows through the fuse.

Fusible link A type of fuse that will melt and open the protected circuit in the event of a short circuit, which could cause excessive current flow through the fusible link. Most fusible links are actually wires that are four gauge sizes smaller than the wire of the circuits being protected.

Gallery Oil from the oil pump first flows through the oil filter, and then goes through a drilled hole that intersects with a drilled main oil gallery, or longitudinal header. This is a long hole drilled from the front of the block to the back.

Galvanic activity Galvanic activity is the flow of an electrical current as a result of two different metals in a liquid, which acts like a battery. Galvanic activity does not require an outside source of voltage.

Garter spring A spring used in a seal to help keep the lip of the seal in contact with the moving part.

Gas fade A type of brake fade where the lining materials are heated enough to emit gas. The gas between the pads and the rotor result in a loss of braking force.

Gasoline direct-injection (GDI) A fuel injection system design in which gasoline is injected directly into the combustion chamber.

Gasoline Refined petroleum product that is used primarily as a gasoline engine.

Gassing The release of hydrogen and oxygen gas from the plates of a battery during charging or discharging.

Gauss gauge A Gauss gauge is a handheld meter that responds to weak magnetic fields. It is used to observe this pulsing magnetic field, which is indicated on the gauge as needle movement.

GC-LB A grease rating for GC is the highest rating for wheel bearing grease and LB is the highest rating for chassis grease. A GC-LB grease, therefore, can be used.

Gear reduction A type of gear arrangement where the driven gear speed is slower than drive gear speed which provides gear reduction.

Gel battery A lead-acid battery with silica added to the electrolyte to make it leakproof and spill proof.

Geometric centerline A type of wheel alignment where all four wheels are aligned parallel to the centerline of the vehicle.

Germanium A semiconductor used in early diodes.

Gerotor A type of positive displacement oil pump uses an inner and an outer rotor. The term is derived from two words: "generated rotor," or gerotor. The inner rotor has one fewer tooth than the outer rotor and both rotate.

Girdle The extra bolts on the main bearing cap help to support the crankshaft when there are high combustion pressures and mechanical loads, especially during high engine speed operation. Many engines use a girdle, which ties all of the main bearing caps together to add strength to the lower part of the block.

Global positioning system (GPS) A government program of 24 satellites that transmit signals that are used by receivers to deter-mine their location.

Global warming potential (GWP) The amount that refrigerants are expected to affect the temperature of planet Earth.

Global warming The increase in average temperature for planet Earth.

Glow plug A glow plug is a heating element that uses 12 volts from the battery and aids in the starting of a cold engine by providing heat to help the fuel to ignite.

GMLAN GM local area network. A type of serial data transmission by General Motors.

GMM Graphing Multimeter.

Grade The strength rating of a bolt.

Grain alcohol Ethanol is also called ethyl alcohol or grain alcohol, because it is usually made from grain and is the type of alcohol found in alcoholic drinks, such as beer, wine, and distilled spirits like whiskey. Ethanol is composed of two carbon atoms and six hydrogen atoms with one added oxygen atom.

Graph A graph is a visual display of information. Graphs are commonly used in the automotive service industry to illustrate trends or specifications along with time or some other variable.

Graticule The series of squares on the face of a scope. Usually 8 by 10 on a screen.

Gravity bleeding Removing air from a hydraulic brake system by opening the bleeder valve and allowing the brake fluid to flow downward and out the bleeder taking any trapped air with it.

Grease fitting A metal replaceable fitting shaped to hold the end of a grease gun in place and equipped with a spring-loaded valve.

Grease seal A seal used to prevent grease from escaping and to prevent dirt and moisture from entering.

Grease Oil with thickener.

Green tire An uncured assembled tire. After the green tire is placed in a mold under heat and pressure, the rubber changes chemically and comes out of the mold formed and cured.

Greenhouse effect Gases in our atmosphere that, if in too great a concentration, can prevent heat from escaping the surface, leading to an increase in the temperature on earth. In a nursery greenhouse, the glass panes are painted white to reflect the heat back into the greenhouse.

Greenhouse gases (GHG) Greenhouse gases (GHG) are those gases in our atmosphere that, if in too great a concentration, can prevent heat from escaping the surface, leading to an increase in the temperature on earth. In a nursery greenhouse, the glass panes are painted white to reflect the heat back into the greenhouse.

Greenhouse gases (GHGs) A layer of gases that traps heat at the Earth's surface and lower atmosphere, and it is increasing the temperature of our living area.

Grid The lead-alloy framework (support) for the active materials of an automotive battery.

Grooves Piston ring grooves are located between the piston head and skirt. The width of the grooves, the width of the lands between the ring grooves, and the number of rings are major factors in determining minimum piston height.

Gross axle weight rating (GAWR) A rating of the load capacity of a vehicle and included on placards on the vehicle and in the owner's manual.

Gross vehicle weight rating (GVWR) The total weight of the vehicle including the maximum cargo.

Gross Gross earnings are the total amount you earned during the pay period.

Ground brushes The brushes in a starter motor that carry current to the housing of the starter or ground.

Grounded A defective component or circuit that is shorted to ground is commonly called grounded.

Groundout Groundout is a vibrating metal A/C line that contacts another surface which produces noise.

Guess-O-Meter (GOM) The dash display that shows the miles per kWh is often called a Guess-O-Meter (GOM) because it is often not accurate.

Guobiao (GB or GB/T) The Chinese national standard. BYD and other Chinese companies use this standard connector, as well as Mahindra and Tata electric vehicles.

GVW Abbreviation for gross vehicle weight. GVW is the weight of the vehicle plus the weight of all passengers and cargo up to the limit specified by the manufacturer.

Hacksaw A saw that uses a replaceable blade and is used to cut a variety of materials depending on the type of blade used.

Half shaft Drive axles on a front-wheel drive vehicle or from a stationary differential to the drive wheels.

Half-shell bearing Modern automotive engines use precision insert-type bearing shells, sometimes called half-shell bearings. The bearing is manufactured to very close tolerance so that it will fit correctly in each application.

Hall-effect switch A semiconductor moving relative to a magnetic field, creating a variable voltage output. Used to determine position. A type of electromagnetic sensor used in electronic ignition and other systems. Named for Edwin H. Hall, who discovered the Hall effect in 1879.

Handwheel position sensor A sensor that detects the direction and speed of rotation of the steering wheel.

Hangers The muffler and tailpipe are supported with brackets, called hangers, which help to isolate the exhaust noise from the rest of the vehicle.

Hard spots Formed in brake drums or rotors due to high heat.

Hazard warning A sticker or decal warning that a hazard is close.

Hazardous waste material Hazardous waste materials are chemicals, or components, that the shop no longer needs that pose a danger to the environment and people if they are disposed of in ordinary garbage cans or sewers.

Head-up display (HUD) The head-up display (HUD), also called a heads-up display, is a supplemental display that projects the vehicle speed and sometimes other data, such as turn-signal information, onto the windshield.

Heat checking A lesser form of drum and rotor cracking is called heat checking, which consists of many small, interlaced cracks on the friction surface.

Heat dams Most pistons have horizontal separation slots that act as heat dams. These slots reduce heat transfer from the hot piston head to the lower skirt. This, in turn, keeps the skirt temperature lower to reduce skirt expansion.

Heat of compression Heat is always generated when air is compressed. The diesel engine requires compression ratios of 16:1 and higher. Incoming air is compressed until its temperature reaches about 1,000°F (540°C).

Heat shield Heat shields are used to protect the underbody of the vehicle from excessive heat created by the exhaust system. Heat shields are usually riveted or screwed into the bottom of the vehicle floor pan above the exhaust system.

Heat shrink tubing A type of rubber tubing that shrinks to about half of its original diameter when heated. Used over a splice during a wire repair.

Heat sink Usually, a metallic-finned unit used to keep electronic components cool.

Heat Molecules in a substance tend to vibrate rapidly in all directions, and this disorganized energy is called heat.

Heated rear window defogger An electrically heated rear window defogger system uses an electrical grid baked on the glass that warms the glass to about 85°F (29°C) and clears it of fog or frost.

Heated seats Heated seats use electric heating elements in the seat bottom, as well as in the seat back, in many vehicles. The heating element is designed to warm the seat and/ or back of the seat to about 100°F (38°C) or close to normal body temperature (98.6°F [37°C]).

Heated steering wheel A heated steering wheel usually consists of the following components: 1. Steering wheel with a built-in heater in the rim. 2. Heated steering wheel control switch 3. Heated steering wheel control module.

Heater core A cooling system component that is responsible for transferring heat from the engine coolant to the passenger compartment.

Heating load The term used when added heat is needed.

Heating, ventilation, and air-conditioning system (HVAC) Driver and passenger comfort is the primary purpose of the heating, ventilation, and air-conditioning system, often abbreviated HVAC

Heel Each slanted ring gear tooth has two ends. Its toe is closest to the ring gear center; its heel, closest to the outside circumference

Height sensor A height sensor determines the vertical relationship between the suspension component and the body of a vehicle.

Height-sensing proportioning valve A valve connected to the rear suspension that limits the brake pressure sent to the rear brakes if the rear of the vehicle is high (unloaded).

Helical gear A helical gear, although similar to a spur gear, has its teeth cut at an angle to the axis of the gear.

Helical insert A steel insert used to repair damaged threads.

Heli-Coil® A brand name for a helical insert.

Helmholtz resonator A tube that is shaped and designed to dampen out certain resonant frequencies that can occur at specific engine speeds. Helmholtz resonator, named for the discoverer of the relationship between shape and value of frequency, Herman L. F. von Helmholtz (1821–1894) of the University of Hönizsberg in East Prussia.

HEPA vacuum High efficiency particulate air filter vacuum used to clean brake dust.

Hertz A unit of measurement of frequency. One Hertz is one cycle per second, abbreviated Hz. Named for Heinrich R. Hertz, a 19th century German physicist.

HEV Hybrid electric vehicle. Describes any vehicle that uses more than one source of propulsion, such as internal combustion engine (ICE) and electric motor(s).

High voltage (HV) High voltage (HV) circuits that if touched with an unprotected hand could cause serious burns or even death.

High-flotation tires High-flotation tires for light trucks are designed to give improved off-road performance on sand, mud, and soft soil and still provide acceptable hard-road surface performance.

High-impedance test meter Digital multimeter (DMM) and digital voltohm-meter (DVOM) are terms commonly used for electronic high-impedance test meters.

High-intensity discharge (HID) A type of headlight that uses high voltage to create an arc inside the arc tube assembly which then produces a blue-white light.

High-pressure common rail (HPCR) Newer diesel engines use a fuel delivery system referred to as a high-pressure common rail (HPCR) design. Diesel fuel under high pressure, over 20,000 PSI (138,000 kPa), is applied to the injectors, which are opened by a solenoid controlled by the computer.

HO2S The four-wire sensor is a heated O2S (HO2S) that uses an O2S signal wire and signal ground. The other two wires are the power and ground for the heater.

Hold-in winding One of two electromagnetic windings inside a solenoid; used to hold the movable core into the solenoid.

Holding devices Apply devices or holding devices are the mechanical or hydraulic assemblies that provide the force to hold or drive members of a planetary gear set.

Holding fixture A holding fixture allows the unit to be rotated yet properly supported during disassembly and reassembly.

Hole theory A theory which states that as an electron flows from negative (-) to positive (+), it leaves behind a hole. According to the hole theory, the hole would move from positive (+) to negative (-).

Homogeneous charge compression ignition (HCCI) A low-temperature combustion process that involves air–fuel mixtures being burned without the use of spark ignition.

Homogeneous mode A mode of operation in a gasoline direct injection system where the air- fuel mixture is the same throughout the cylinder.

Hooke's Law The force characteristics of a spring discovered by Robert Hooke (1635-1703). An English physicist. Hooke's Law states "the deflection (movement or deformation) of a spring is directly proportional to the applied force."

Horns An electromechanical device that creates a loud sound when activated.

Horsepower A unit of power; 33,000 foot-pounds per minute. One horsepower equals 746 W.

Hotchkiss drive A type of power transmission for a front engine, rear-drive vehicle where the engine torque reaction is controlled by the suspension as compared to the use of torque arm or frame-mounted differential.

Housekeeping Housekeeping is the responsibility of all personnel to keep all areas of the business clean and orderly. Lost sales can result from a disorderly and sloppy appearance. Counter tops, shelves, and displays should all be neat and clean. Good housekeeping leads to a safe, clean, and productive environment.

Housing expense Includes rent or mortgage payment, plus heat, light, and other utility expenses.

HTHS ACEA oil also requires low levels of sulfated ash, phosphorous, and sulfur, abbreviated SAPS, and has a high-temperature/ high-shear rate viscosity, abbreviated HTHS

Hub (Crankshafts, Balance Shafts, and Bearings) This damper or balancer usually consists of a cast-iron inertia ring mounted to a cast-iron hub with an elastomer sleeve.

Hub (Manual Transmissions/Transaxles) In synchronizer construction there are a number of design variations. All are similar and include a hub, a sliding sleeve, a blocker ring, (or stop ring or synchronizer ring), keys, and springs.

Human-machine interface (HMI) A human-machine interface (HMI) is the user interface that connects an operator to the controller for a vehicle.

Hunting gear sets Hunting gear sets are gear sets with final drive ratios expressible in a fraction that cannot be reduced to any lower terms

Hybrid electric vehicle (HEV) Hybrid electric vehicles (HEV) are vehicles that have two sources of propulsion either with an electric motor supplied energy from the high-voltage battery or an internal combustion engine (ICE).

Hybrid organic acid technology (HOAT) A type of coolant that has organic acids and either no phosphates and some silicates, or no silicates and some phosphates. Coolants can be green, orange, yellow, gold, pink, red, or blue.

Hydraulic electronic unit injection (HEUI) Ford 7.3, 6.0, and 6.4 liter (and Navistar) diesels use a system called a hydraulic electronic unit injection system, or HEUI system. The components used include: 1. High-pressure engine oil pump and reservoir 2. Pressure regulator for the engine oil and 3. Passages in the cylinder head for flow of fuel to the injectors. The engine oil is pressurized to provide an opening pressure strong enough to overcome the fuel pressure when the solenoid is commanded to open by the PCM.

Hydraulic impulse storage accumulator A hydraulic impulse storage accumulator is used to provide fluid pressure as the internal combustion engine (ICE) restarts after the idle stop mode.

Hydraulic lash adjusters (HLA) Overhead camshaft engines use several different types of valve opening designs. Some newer engines have the hydraulic adjustment in the rocker arm and are commonly called hydraulic lash adjusters (HLA).

Hydraulic press A piece of shop equipment usually mounted on the floor, which uses a hydraulic cylinder to remove and install pressed-on components, such as bearings.

Hydraulic valve lifter Valve train clearance is also called valve lash, which is needed to help compensate for thermal expansion and wear. Valve train clearance must not be excessive, or it causes noise or results in premature failure. One method commonly used to make the necessary valve clearance adjustments involves a lifter with an automatic hydraulic adjustment built into the lifter body, called a hydraulic valve lifter.

Hydrocarbons (HC) Any of a number of compounds of carbon and hydrogen used as fuel, such as gasoline. High levels of hydrocarbons in tailpipe emissions are a result of unburned fuel. When combined with NOx and sunlight, they form smog.

Hydrocracking A refinery process that converts hydrocarbons with a high boiling point into ones with low boiling points.

Hydrodynamic lubrication A wedge-shaped oil film is built up between the moving block and the surface. High oil pressure created between the crankshaft journal and the bearing created by the rotation of the oil film.

Hydrokinetic pump The word hydro means liquid and the term kinetic refers to motion, so the term hydrokinetic pump means that this design of pump rapidly moves the fuel to create pressure. This design of pump is a nonpositive displacement pump design.

Hydrometer An instrument used to measure the specific gravity of a liquid. A battery hydrometer is calibrated to read the expected specific gravity of battery electrolyte.

Hydroplaning Condition that occurs when driving too fast on wet roads where the water on the road gets trapped between the tire and the road forcing the tire onto a layer of water and off the road surface. All traction between the tire and the road is lost.

Hydroseal The cold soak tank is used to remove grease and carbon. The disassembled parts are placed in the tank so that they are completely covered with the chemical cleaning solution. Usually, there will be a layer of water over the chemical to prevent evaporation of the chemical. This water layer is called a hydroseal.

Hygrometer Relative humidity is commonly measured with a hygrometer or a psychrometer. A hygrometer depends on a sensitive element that expands and contracts, based on the humidity. Hygrometers typically resemble a clock, with the scale reading from 0% to 100% relative humidity.

Hygroscopic Ability of brake fluid to absorb moisture from the air.

Hypereutectic A standard cast aluminum piston contains about 9% to 12% silicon and is called a eutectic piston. To add strength, the silicon content is increased to about 16%, and the resulting piston is called a hypereutectic piston.

Hypoid gear set A ring gear and pinion gear set that meshes together below the center line of the ring gear. This type of gear set allows the drive shaft to be lower in the vehicle, yet requires special hypoid gear lubricant.

Hypothesis Proposed explanation made on the basis of limited evidence as a starting point for further investigation. Use the explanation (hypothesis) to test to see if it matches the existing problem.

H-block The H-block design is a type of TXV that uses four passages and controls the refrigerant flow using opposing pressures.

Identifier A tester used to determine what the correct refrigerant is for the system being service.

Idle speed control (ISC) motor Idle airflow in a TBI system travels through a passage around the throttle and is controlled by a stepper motor. In some applications, an externally mounted permanent magnet motor, called the idle speed control (ISC) motor.

Idle stop Idle stop means that the engine is not running, but could start at any time if the computer detects the need to charge the hybrid batteries, or any other issue that requires the gasoline engine to start and run.

Idle vacuum test An engine in proper condition should idle with a steady vacuum between 17 and 21 inch Hg

IEC International Electrotechnical Commission.

Igniter The negative terminal is attached to an ignition control module (ICM or igniter), which opens and closes the primary ignition circuit by opening or closing the ground return path of the circuit.

Ignition coil An electrical device consists of two separate coils of wire: a primary and a secondary winding. The purpose of an ignition is to produce a high-voltage (20,000 to 40,000 V), low-amperage (about 80 mA) current necessary for spark ignition.

Ignition control module (ICM) The ignition system includes the ignition coil(s), after coil which creates a high voltage spark by stepping up battery voltage using an ignition control module (ICM).

Ignition timing The exact point of ignition in relation to piston position.

Impact wrench An air-operated hand tool used to install and remove threaded fasteners.

Impedance The resistance of a coil of wire, measured in ohms.

Impeller The mechanism in a water pump that rotates to produce coolant flow.

Impulse Item An impulse item is a product that the customer buys to fill a want rather than a need.

Impurities Doping elements.

Incentive pay The hourly rate can vary greatly depending on the experience of the technician and type of work being performed. Most experienced service technicians are paid by a method called flat-rate. The flat-rate method of pay is also called incentive or commission pay. “Flat-rate” means that the technician is paid a set amount of time (flat-rate) for every service operation. The amount of time allocated is published in a flat-rate manual.

Inches of mercury (In. Hg) A measurement of vacuum; pressure below atmospheric pressure.

Inches of mercury (inch Hg) Unit of measure used to measure a vacuum.

Inclinometer An instrument used to measure angles. Normally used to measure driveshaft angles.

Included angle SAI angle added to the camber angle of the same wheel. Includes starter motor, starter solenoid/relay, battery, neutral safety switch, ignition including co-solvents, in unleaded gasoline is limited by law to 5 percent.

Independent suspension A suspension system that allows a wheel to move up and down without undue effect on the opposite side.

Indicator ball joints A type of ball joint that shows when the joint is worn enough to require replacement.

Indirect injection (IDI) In an indirect injection (abbreviated IDI) diesel engine, fuel is injected into a small prechamber, which is connected to the cylinder by a narrow opening. The initial combustion takes place in this prechamber. This has the effect of slowing the rate of combustion, which tends to reduce noise

Inductive ammeter A type of ammeter that is used a Hall Effect senor in a clamp that is used around a conductor carrying a current.

Inductive reactance An opposing current created in a conductor whenever there is a charging current flow in a conductor.

Inert The recirculated exhaust gas is inert (chemically inactive) and does not enter into the combustion process.

Inertia ring Harmful crankshaft twisting vibrations are dampened with a torsional vibration damper. It is also called a harmonic balancer. This damper or balancer usually consists of a cast-iron inertia ring mounted to a cast-iron hub with an elastomer sleeve.

Inertia switch The inertia switch is installed in the rear of the vehicle between the electric fuel pump and its power supply. With any sudden impact, such as a jolt from another vehicle in a parking lot, the inertia switch opens and shuts off power to the fuel pump.

Inertia Energy in a moving object.

Inflator module The part of an airbag that contains the airbag itself, plus the unit that is used to inflate the airbag.

Informal evaluation In many cases, a beginning technician's activities are simply observed and noted, which is a type of informal evaluation. Both are usually done and both can influence the technician's pay.

Infrared (IR) sensors A type of sensor used in many automatic air-conditioning systems that are used to detect the temperature of the passenger areas.

Initial timing If the engine is equipped with a distributor, it may be possible to adjust the base or the initial timing. The initial timing is usually set to fire the spark plug between zero degrees (top dead center or TDC) or slightly before TDC (BTDC).

Injection pump A diesel engine uses a fuel system with a precision injection pump and individual fuel injectors. The pump delivers fuel to the injectors at a high pressure and at timed intervals.

Inline engine Early engines used four or six cylinders arranged inline. These are called inline engines and are still produced today.

Inline filters A filter that can be installed into a refrigerant line that is designed to trap foreign particles.

Inner liner The inner layer of rubber inside a tire.

Inorganic additive technology (IAT) Inorganic additive technology (IAT) is conventional coolant that has been used for over 50 years. Most conventional green antifreeze contains inorganic salts.

Input conditioning What the computer does to the input signals to make them useful; usually includes an analog to digital converter and other electronic circuits that eliminate electrical noise.

Input member The drive member of a planetary gear set is called the input member.

Input shaft The input shaft is splined to the clutch disc and is also referred to as the main gear, clutch gear, or main drive pinion assembly. The main shaft, also called the output shaft, is splined at the end and transmits engine torque to the drive shaft (propeller shaft) through a yoke and universal shaft.

Input speed sensor (ISS) The sensor that measures the speed of the input shaft which is the same or almost the same as the engine speed. This is also called turbine speed sensor (TSS) because it is used to determine the speed of the turbine shaft.

Input Information on data from sensors to an electronic controller is called input. Sensors and switches provide the input signals.

Insert seats An insert seat fits into a machined recess in the steel or aluminum cylinder head. Insert seats are used in all aluminum head engines and in applications for which corrosion and wear resistance are critical.

Inside air Inside air is usually called recirculation

Installed height Valve stem height is the distance the valve stem is above the spring seat. Valve stem height is a different measurement from installed height.

Instrument panel (IP) All vehicles are equipped with war warning lights on the instrument panel (IP) and they are often confusing to drivers. Symbols are used instead of words because they are universal in a global vehicle market.

Instrument panel cluster (IPC) Vehicle information is displayed on the instrument panel cluster (IPC).

Insulated brushes Brushes used in a starter motor that connect to battery power through the solenoid.

Insulator A material that does not readily conduct electricity and heat. A nonmetal material that contains more than four electrons in its atom's outer shell.

Insulators Thin strips of plastic or hard rubber used to separate the leaves of a leaf spring.

Intake manifold All engines, both gasoline and diesel engines, draw air from the atmosphere. It requires about 9,000 gallons of air for each gallon of gasoline used. The air must be drawn where deep water in the road cannot be drawn into the engine. The air is then filtered by a replaceable air filter. After the air is filtered, it passes through a throttle valve and then into the engine through an intake manifold.

Intake valve A valve in the cylinder head of an internal-combustion engine that opens at the proper moment to allow a mixture of fuel and air to be drawn into the cylinder. The intake valve is open and the piston inside the cylinder travels downward, drawing a mixture of air and fuel into the cylinder.

Integral accumulator Piston-type accumulators look and function much like servo pistons. In fact, some piston-type accumulators share a bore with one of the transmission servos. This common bore design is known as an integral accumulator.

Integral reservoir A type of power steering pump that includes the pump inside the fluid reservoir.

Integral seat The valve face closes against a valve seat to seal the combustion chamber. The seat is generally formed as part of the cast-iron head of automotive engines, called an integral seat.

Integral sensors A term used to describe a crash sensor that is built into the airbag control module.

Integrally molded Disc brake pads where the friction material is molded and locked into holes in the steel backing plate.

Integrated circuit (IC) An electronic circuit that contains many circuits all in one chip.

Intelligent Speed Advice (ISA) Intelligent Speed Advice (ISA) uses a sign recognition camera or a navigation system (GPS) to determine the speed limit, which is used to warn the driver of the posted speed limit.

Interaxle differential (center differential) All-the-time four-wheel-drive, all-wheel-drive, and full-time four-wheel-drive systems use an interaxle differential (center differential) to prevent driveline harshness and vibration, commonly referred to as driveline windup.

Intercooler Power can be increased by cooling the compressed air after it leaves the turbocharger. The power can be increased about 1% per 10°F by which the air is cooled. A typical cooling device is called an intercooler.

Interference engine An interference engine, however, causes some of the valves that are open to hit the pistons, causing major engine damage.

Interference fit A method of retaining the piston pin in the connecting rod is to make the connecting rod hole slightly smaller than the piston pin. The pin is installed by heating the rod to expand the hole or by pressing the pin into the rod. This retaining method securely holds the pin. This press or shrink fit is called an interference fit.

Intermediate lever A lever used as part of the parking brake cable system.

Intermediate oscillations After the spark has stopped, some energy remains in the coil. This remaining energy dissipates in the coil windings and the entire secondary circuit. The intermediate oscillations are also called the “ringing” of the coil as it is pulsed.

Internal combustion engine (ICE) If engine combustion occurs within the power chamber, the engine is called an internal combustion engine.

Internal combustion engine All gasoline and diesel engines are called internal combustion engines and are designed to compress an ignitable mixture. This mixture is ignited by using a spark (gasoline) or by heat of compression (diesel).

Internal gear The outer ring gear has teeth on the inside that mesh with the teeth of the planet pinion gears. The ring gear is also called the annulus gear or internal gear because the gear teeth are on the inside (rather than the outside) portion of the gear.

Internal ring gears Gears having teeth along the inside circumference are called internal ring gears. The teeth of an internal ring gear may be spur or helical teeth.

International Lubricant Standardization and Approval Committee (ILSAC) Responsible for development of the ILSAC standard for motor oil performance.

In-vehicle temperature sensor A thermistor used to measure the temperature of the interior of a vehicle and used in automatic air-conditioning systems.

Inventory Discrepancy Form After a physical inventory has been completed, the discrepancies must be recorded and logged into the computer system. The cause of the discrepancy needs to be identified (wrong stock number, stolen, transfers to other stores, incorrect part numbers or quantities of parts picked off the shelf. The parts specialist will need to take action to eliminate discrepancies by using an inventory discrepancy form.

Inverter An electronic device used to convert DC (direct current) into AC (alternating current).

Invoice The invoice lists all parts by names and is used to track inventory and purchases for billing purposes.

IOD Ignition off draw. A Chrysler term used to describe battery electrical drain or parasitic draw.

Ion An atom with an excess or deficiency of electrons forming either a negative or a positive charged particle.

Iridium spark plugs Iridium is a white precious metal and is the most corrosion-resistant metal known. Most iridium spark plugs use a small amount of iridium welded onto the tip of a small center electrode 0.0015 to 0.002 inches (0.4 to 0.6 mm) in diameter.

Irradiance The term used to define the amount of solar radiation is irradiance. The solar irradiance at the earth’s surface varies greatly depending on factors such as: Latitude, Time of day, Time of year, Cloud cover, and Haze.

IRS Independent rear suspension.

ISO International Standards Organization.

Jack stands A metal device with an adjustable vertical support that is designed to support a vehicle after it has been raised off the ground. Also called a safety stand.

Jam nut A second nut used to prevent the first nut from loosening.

Job shadowing Job Shadowing is a career exploration activity that offers the Student Technician to spend time with a working Technician in an area of interest. A great way to see what it is really like to work as a service technician is to follow a professional around for a day or more. Job shadowing is usually arranged through an automotive program, and the shop or dealership has agreed to allow someone into the shop area to observe.

Jobber parts Jobber parts (or aftermarket parts) are not made by the original manufacturer of the vehicle. The aftermarket industry makes up about 80% of the parts used in vehicle repair.

Jobber Most aftermarket parts are sold at automotive parts stores or jobbers. A jobber or parts retailer usually gets parts from a large regional warehouse distributor.

Jumper cables Heavy-gauge (4 to 00) electrical cables with large clamps, used to connect a vehicle that has a discharged battery to a vehicle that has a good battery.

Junction The point where two types of materials join.

JWL Japan Wheel Light Metal Standard Mark.

KAM Keep alive memory.

Kelvin (K) A temperature scale where absolute zero is zero degrees. Nothing is colder than absolute zero.

Key fob A decorative unit attached to keys. Often includes a remote control to unlock/lock vehicles.

Keys In synchronized construction there are a number of design variations, all are similar and include a hub, a sliding sleeve, a blocker ring, (or stop ring or synchronizer ring), keys, and springs.

Kickback The movement of the steering wheel when the front wheels strike a curb or bump.

Kilo (k) Means 1,000; abbreviated k or K.

Kilowatt-hour (kWh) kWh is a unit of energy. Battery capacity is measured in kilowatt-hours (kWh). A kilowatt is 1,000 watts and a watt is a volt times an ampere, which is a measurement of electrical power. The higher the kWh rating of the battery, the more electrical energy it can store.

Kinetic energy The energy in any moving object. The amount of energy depends on the weight (mass) of the object and the speed of the object.

Kingpin Used on an I-beam or twin I-beam front suspension, A kingpin steering knuckle keeps the wheel rigid in relation to the I-beam during up-and-down wheel movement, but rotates around the steering axis to turn the wheels left and right.

Kingpins Kingpins allow the front wheels to rotate for steering. Kingpins are hardened steel pins that attach the steering knuckle to the front axle.

Kirchhoff’s current law A law that states: “The current flowing into any junction of an electrical circuit is equal to the current flowing out of that junction.” Lightemitting - Light-emitting diode (LED) trouble lights are excellent to use because they are shock resistant, long lasting, and do not represent a fire hazard.

Kirchhoff’s voltage law A law about electrical circuits that states: “The voltage around any closed circuit is equal to the sum (total) of the resistances.”

Knock sensor (KS) A sensor that can detect engine spark knock.

KPI Steering axis inclination (SAI) is also known as kingpin inclination (KPI) and is the imaginary line drawn through the kingpin as viewed from the front.

kWh/100 mi The EPA also expresses an EV’s energy consumption in terms of the number of kilowatts per hour needed to run the vehicle for 100 miles shortened to kWh/100 mi. For example, a Tesla Model 3 usually uses about 28 kW per 100 miles.

Labor guides A guide that shows the estimated labor times for each service or procedure.

Labyrinth seal A water seal formed by the curved area at the lip of the backing plate and the notch in the brake drum.

Ladder frame A steel frame for a vehicle that uses cross braces along the length, similar to the rungs of a ladder.

Lands Piston ring grooves are located between the piston head and skirt. The width of the grooves, the width of the lands between the ring grooves, and the number of rings are major factors in determining minimum piston height.

Lane departure warning system (LDWS) The lane departure warning system (LDWS) uses cameras to detect if the vehicle is crossing over lane marking lines on the pavement.

Lane keep assist (LKA) A lane keep assist (LKA) will warn the driver if the vehicle is moving out of the lane of traffic, but when no response, to also automatically use the electric power steering system to steer the vehicle back into the lane.

Lane-departure warning Lane-departure warning, also called Lane-keeping Assist often uses a small vibration in the seat to warn the driver that the vehicle is close to the center line, and can often actually steer the vehicle back into the lane

Lap On nonhunting and partially nonhunting gears, manufacturers lap the contacting gear teeth to decrease wear. For this reason, these gear sets are marked to ensure proper alignment during assembly procedures.

Lapelletier gear set The Lapelletier gear set is constructed by connecting a planetary gear set in front of a Ravigneaux gear set.

Lash The valve clearance or lash must be set on a solid lifter engine, so that the valves can positively seat.

Latent heat Heat that causes a change in state without a change in temperature.

Lateral acceleration sensor The function of the lateral acceleration sensor is to provide the suspension control module with feedback regarding vehicle cornering forces.

Lateral accelerometer sensor A sensor used in many vehicles equipped with electronic suspension and/or traction control systems used to detect sideways movement of the vehicle.

Lateral links Suspension arms that control the side-to-side movement of the wheels and vehicle. Also called transverse links.

Lateral runout (LRO) Lateral runout, often abbreviated LRO, is side-to-side wobble of the rotor as it rotates on the spindle.

Lateral runout A possible problem that tires can cause is a type of vibration called shimmy, which is the rapid back-and-forth motion transmitted through the steering linkage to the steering wheel. Excessive lateral runout is usually noticeable by the driver of the vehicle as a side-to-side vibration, especially at low speeds between 5 and 45 mph (8 and 72 km/h).

Lay shaft All manual transmissions/transaxles use a countershaft (also called a lay shaft or cluster shaft) to provide the other set of gears necessary to achieve the changes in gear ratios. The gears on the countershaft are called cluster gears or counter gears.

Lead A lead or drift is a mild pull that does not cause a force on the steering wheel that the driver must counteract.

Leading shoe The forward facing brake shoe on a leading/trailing type of drum brake.

Leading-trailing brakes A type of drum brake design which anchors the bottom of both shoes to the backing plate.

Leaf mark Washington State legislation mandates that all brake pads and shoes manufactured after January 1, 2015, are required to have a leaf mark icon indicating the level of compliance with state friction material content legislation.

Leaf springs Leaf springs are constructed of one or more strips of long, narrow spring steel. These metal strips, called leaves, are assembled with plastic or synthetic rubber insulators between the leaves, allowing for freedom of movement during spring operation.

Leak detection pump (LDP) Many vehicles use a vacuum operated leak detection pump (LDP) as part of the evaporative control system diagnosis equipment.

Lean indicator If O2 is high, the exhaust is lean, so O2 is called the "lean indicator"

LED test light An LED test light uses a light-emitting diode (LED), instead of a standard automotive bulb, for a visual indication of voltage.

Ledges Also called shoe pads, where the brake lining controls the backing plate.

Left-hand rule A method of determining the direction of magnetic lines of force around a conductor. The left-hand rule is used with the electron flow theory (- flowing to +).

Leg Another name for the branches of a parallel circuit.

Lenz's law The relative motion between a conductor and a magnetic field is opposed by the magnetic field of the current it has induced.

Lever style (pressure plate) Coil spring style. This style of pressure plate uses coil springs and three or four release arms. A coil-spring-style pressure plate is also called the lever style because it uses levers to compress the coil springs

Leverage The ability of a lever or other mechanical device used to increase force.

Leyden jar A device first used to store an electrical charge. The first type of capacitor.

Lift pump The diesel fuel is usually drawn from the fuel tank by a separate pump, called a lift pump, and delivers the fuel to the injection pump.

Light-emitting diode (LED) A high-efficiency light source that uses very little electricity and produces very little heat.

Lightly Loaded Vehicle Weight (LLVW) The actual performance tests are made with the vehicle loaded to both the manufacturer's specified gross vehicle weight rating (GVWR) and the lightly loaded vehicle weight (LLVW), with certain applied brake forces. There are precise instructions for every step of the test, including the number of times the tests must be repeated, the sequence of the testing, and the allowable stopping distance for the particular type of vehicle.

Light-off converter (LOC) Some vehicles have used a small, quick heating oxidation converter, called a preconverter or a pup (mini) converter, that connects directly to the exhaust manifold outlet. These have a small catalyst surface area close to the engine that heats up rapidly to start the oxidation process more quickly during cold engine warm-up. For this reason, they were often called light-off converters (LOCs).

Light-off temperature The catalytic converter does not work when cold, so it must be heated to its light-off temperature of close to 500°F (260°C) before it starts working at 50% effectiveness. When fully effective, the converter reaches a temperature range of 900°F to 1,600°F (482°C to 871°C). In spite of the intense heat, however, catalytic reactions do not generate a flame associated with a simple burning reaction.

Light-off time (LOT) The time it takes for an oxygen sensor to be start to work.

Limp-in gear A default (or limp-in) gear is the forward speed that is used if there is a failure in the electronic or computer system. If neither solenoid is engaged, then either second or third gear is actuated, depending on the exact make and model of the transmission or transaxle.

Line pressure solenoid (LPS) The solenoid that controls the line pressure to the transmission hydraulic system.

Linear EGR valve Most General Motors and many other vehicles use a linear EGR valve that contains a pulse-width modulated solenoid to precisely regulate exhaust gas flow and a feedback potentiometer that signals the PCM regarding the actual position of the valve.

Lining fade A condition where the brake lining overheats, reducing the coefficient of friction.

Lining table The part of a drum brake shoe where the lining is attached.

Lip seal A type of seal used on A/C compressors. The lip of the seal is made from Teflon and rides against a perfectly smooth portion of the drive shaft.

Liquid crystal display (LCD) A display that uses liquid crystals to display waveorms and text on its screen.

Liquid line The line that connects the condenser outlet to the receiver–drier inlet or orifice tube and the receiver–drier outlet to the TXV.

Liquified petroleum gas (LPG) Another term for propane.

Listening To make an effort to hear someone. Good listening requires that we focus our attention on those speaking to us.

Lithium iron phosphate (LiFePO4) Lithium iron phosphate (LiFePO4) is a type of battery chemistry that is stable at higher temperatures and does not contain cobalt, which is in limited supply world-wide.

Lithium-based brake grease Lubrication of moving or sliding components prevents noise from being generated as the parts move over each other. Many vehicle manufacturers recommend Lithium-based brake grease.

Live axle If engine torque is applied to the rear axle to drive the vehicle, the axle is referred to as a live axle.

Load Index An abbreviated method that uses a number to indicate the load carrying capabilities of a tire.

Load test A type of battery test where an electrical load is applied to the battery and the voltage is monitored to determine the condition of a battery.

Load A term used to describe a device when an electrical current is flowing through it.

Load-carrying ball joint If the coil spring is attached to the top of the upper control arm, then the upper ball joint is carrying the weight of the vehicle and is called the load-carrying ball joint.

Loaded calipers Loaded calipers are remanufactured calipers that include (come loaded with) the correct replacement friction pads and all the necessary hardware.

Lobe centers Separation between the centerlines of the intake and exhaust lobes, measured in degrees.

Lobe displacement angle (LDA) Another camshaft specification that creates some confusion is the angle of the centerlines of the intake and exhaust lobes. This separation between the centerlines of the intake and exhaust lobes is called lobe displacement angle (LDA).

Lobe lift The lobe lift of the cam is usually expressed in decimal inches and represents the distance that the valve lifter or follower is moved.

Lobe separation Another camshaft specification that creates some confusion is the angle of the centerlines of the intake and exhaust lobes. This separation between the centerlines of the intake and exhaust lobes is called lobe separation.

Lobe spread Another camshaft specification that creates some confusion is the angle of the centerlines of the intake and exhaust lobes. This separation between the centerlines of the intake and exhaust lobes is called lobe spread.

Lobe Camshafts have eccentric shapes called lobes that open the valve against the force of the valve springs.

Lock plate A plate located in the steering column that is used to lock the steering wheel when the key is removed from the ignition.

Lock ring Full-floating piston pins use some type of lock ring to retain the piston pin. There are two common types of lock rings: 1. Internal snap ring and 2. Spiral lock ring.

Lock tang A mechanical tab that is used to secure a terminal into a connector. This lock tang must be depressed to be able to remove the terminal from the connector.

Locking pliers Pliers that can be used to grasp an object and then be locked into position. Often called by a popular brand name VISE-GRIPS®.

Locks The valve keepers (also called locks) secure the spring retainer to the stem of the valve.

Locksmith ID In order to obtain module reprograming information or to replace a module, the shop or service technician must be a registered vehicle security professional and have a locksmith ID number. The National Automotive Service Task Force (NASTF), in conjunction with automotive manufacturers, insurance industry, independent repair, and law enforcement communities, has developed this system to allow the aftermarket repair industry to access to this sensitive data.

Logic probe A type of tester that can detect either power or ground. Most testers can detect voltage but most of the others can not detect if a ground is present without further testing.

Long block The replacement assembly is called a long block when the reconditioned assembly includes the heads and valve train.

Loss Leader A loss leader is a product that is sold for less than the usual or expected price in an effort to entice customers to visit the parts store to purchase the item.

Lost Sales Report A lost sales report will show new part numbers that the store does not stock along with older part numbers that are increasingly in demand. Some part numbers will have an instant demand, such as those found in some of the newer vehicles. Other parts will grow in demand, but more slowly.

Low range A low range may be selected to deliver high torque at low speeds to the drive wheels. Low range usually provides a 2:1 to 3:1 gear reduction. High range (usually 1:1) simply transfers engine torque at the same speed as the output shaft of the transmission.

Low-drag caliper A type of disc brake caliper where the piston retracts more than usual, reducing the brake drag between the pad and the rotor.

Low-grade heat Heat is generated by the fuel cell during normal operation. Excess heat can lead to a breakdown of the polymer electrolyte membrane, so a liquid cooling system must be utilized to remove waste heat from the fuel-cell stack. One of the major challenges for engineers in this regard is the fact that the heat generated by the fuel cell is classified as low-grade heat.

LP-gas Propane is the most widely used of all of the alternative fuels. Propane is normally a gas but is easily compressed into a liquid and stored in inexpensive containers. When sold as a fuel, it is also known as liquefied petroleum gas (LPG) or LP-gas because the propane is often mixed with about 10% of other gases.

LRR Low-rolling-resistance (LRR) tires reduce rolling resistance, which is the power-robbing friction between the tire and crown.

Lube oil The ATF returns to the transmission/transaxle to passages that lubricate the internal moving parts. This returned fluid is called lube oil.

Lug nuts Nuts used on wheel studs to attach wheels to hubs.

Lugging Never lug any engine. Lugging means increasing the throttle opening without increasing engine speed (RPM).

M85 Internal combustion engine fuel containing 85% methanol and 15% gasoline.

Magnetic flux The lines of force produced in a magnetic field.

Magnetic induction The transfer of the magnetic lines of force to another nearby metal object or coil of wire.

Magnetic sensor A magnetic sensor uses the changing strength of the magnetic field surrounding a coil of wire to signal the module and computer.

Magnetism A form of energy that is recognized by the attraction it exerts on other materials.

Magneto-rheological (MR) MR fluid shocks use a working fluid inside the shock that can change viscosity rapidly depending on electric current sent to an electromagnetic coil in each device. The fluid is called magneto-rheological (Mr) and is used in monotube-type shock absorbers.

Main drive pinion assembly The input shaft is splined to the clutch disc and is also referred to as the main gear, clutch gear, or main drive pinion assembly. The main shaft, also called the output shaft, is splined at the end and transmits engine torque to the drive shaft (propeller shaft) through a yoke and universal shaft.

Main gear The input shaft is splined to the clutch disc and is also referred to as the main gear, clutch gear, or main drive pinion assembly. The main shaft, also called the output shaft, is splined at the end and transmits engine torque to the drive shaft (propeller shaft) through a yoke and universal shaft.

Main shaft The input shaft is splined to the clutch disc and is also referred to as the main gear, clutch gear, or main drive pinion assembly. The main shaft, also called the output shaft, is splined at the end and transmits engine torque to the drive shaft (propeller shaft) through a yoke and universal shaft.

Major splice A place in a tire where the tread rubber and one or more body plies are spliced during tire construction.

Major thrust surface The side of an engine cylinder that receives the greatest thrust or force from the piston during the power stroke.

Malfunction indicator lamp (MIL) This amber, dashboard warning light may be labeled check engine or service engine soon.

Manifold absolute pressure (MAP) sensor Sensor used to measure the pressure inside the intake manifold compared to a perfect vacuum.

Manual valve The manual valve is the primary flow-directing valve in an automatic transmission. This valve connects to a shift lever in the transmission, which in turn connects to the gear selector lever through a mechanical linkage. The driver controls manual valve position through the gear selector and shift linkage.

Manufacturer's suggested retail price (MSRP) The Monroney label is the sticker on the vehicle that lists the manufacturer's suggested retail price, usually abbreviated MSRP. The law that requires this label on all vehicles is called the Monroney Law, named for the congressman who sponsored the bill, Almer S. Monroney (1902–1980), a U.S. farm representative from Oklahoma from 1939 to 1951 and a U.S. Senator from 1951 to 1969.

Marcel spring The torsional dampers are either coil springs or are made of rubber. In the space between the friction surfaces is a wavy spring steel material called a cushioning spring or marcel spring.

Mass airflow (MAF) sensor Unlike the air vane sensor, the MAF sensor takes into account relative humidity, altitude, and temperature of the air. The denser the air, the greater the cooling effect on the hot film sensor and the greater the amount of fuel required for proper combustion.

Mass The weight of an object. A measure of the amount of material contained in an object. Gravity acts on a mass to give it weight.

Master cylinder The part of the brake hydraulic system where the pressure is generated.

Match mounting Mount the tires on the rim with the valve stem matched to (lined up next to) the mark on the tire or with the major splice. This is called match mounting.

MCA Marine cranking amps. A battery specification.

Mechanical advantage The use of levers, such as a brake pedal to increase the force applied by the driver.

Mechanical fade Braking reduction caused by the heat expansion of the brake drum away from the brake lining.

Mechanical force A mechanical force involves contact with another object. The pressure developed within the combustion chamber is applied to the head of a piston to produce a usable mechanical force, which is converted into useful mechanical power.

Mechanical power Mechanical power. Power is the rate at which work is done. The pressure developed within the combustion chamber is applied to the head of a piston to produce a usable mechanical force, which is converted into useful mechanical power.

Mechanical refrigeration A cooling process that involves pumping a chemical with a very low boiling point through a series of heat exchangers.

Mechanical returnless fuel system (MRFS) A returnless fuel delivery system design that uses a mechanical pressure regulator located in the fuel tank.

Medium hybrid A hybrid electric vehicle design that utilizes "medium" voltage levels (between 50 and 200 volts). Medium hybrids use regenerative braking and idle stop but are not capable of starting the vehicle from a stop using electric mode.

Mega (M) Million. Used when writing larger numbers or measuring large amount of resistance.

Membrane electrode assembly (MEA) The part of the PEM fuel cell that contains the membrane, catalyst coatings, and electrodes.

Memory steer Memory steer is a lead or pull of a vehicle caused by faults in the steering or suspension system. If after making a turn, the vehicle tends to pull in the same direction as the last turn, then the vehicle has memory steer.

Mentor An experienced technician who offers to help a beginning technician learn all aspects of the trade.

Mercury A heavy metal.

Mesh spring A spring used behind the starter pinion on a starter drive to force the drive pinion into mesh with the ring gear on the engine.

Metal Inert Gas (MIG) Is an arc welding process that uses a continuous solid wire electrode heated and fed into the weld pool from a welding gun. The two base materials are melted together forming a joint. The gun uses a shielding gas around the electrode to protect the weld pool from oxidation. The MIG welder is currently used for welding panels and structural components together. MIG welding can repair high-strength steel without harming or weakening it.

Meter accuracy The accuracy of a meter measured in percent.

Meter resolution The specification of meter that indicates how small or fine a measurement the meter can detect and display.

Metering valve (Hold-off valve) A valve installed between the master cylinder and front disc brakes which prevents operation of front disc brakes until 75-125 psi is applied to overcome rear drum brake return spring pressure.

Metric bolts Bolts manufactured and sized in the metric system of measurement.

Metric wire gauge The metric method for measuring wire size in the square millimeters. This is the measure of the core of the wire and does not include the insulation.

Micro-hybrid drive A term used to describe Belt Alternator Starter (BAS) and other mild hybrid systems.

Microinches (μin) The smoothness of the rotor is called rotor finish or surface finish. Surface finish is measured in units called microinches, abbreviated μin..

Micron A unit of length equal to one millionth of a meter. One micron is equal to 0.000039 inch.

Mild hybrid A hybrid electric vehicle design that utilizes regenerative braking and idle stop but cannot propel the vehicle in electric-only mode. Also called an assist hybrid and typically operates below 50 volts.

Miles per hour (MPH) Level 2 charging adds about 25 miles of Range Per Hour (RPH), labeled as miles per hour (MPH) on the dash display of a Nissan Leaf.

Milli (m) One thousandth of a volt or ampere.

Millimeters of mercury (Mm Hg) A metric measure of vacuum.

Mineral oil Mineral oil is used in R-12 refrigerant systems.

Minutes There are 60 minutes (written as 60') in 1 degree.

Miscible Oils must be miscible, meaning they are capable of mixing with other oils (brands and viscosities, for example) without causing any problems, such as sludge

Mode door A flap valve that moves to divert airflow to the floor, instrument panel, or windshield outlets.

Mode select switch A switch used to select ride comfort settings on a vehicle equipped with electronic suspension.

Mode shift Either two-wheel drive or four-wheel drive may be selected. Many transfer cases also have a neutral position. The mode shift is achieved by the use of a floor-mounted lever to engage and disengage a clutch inside the transfer case.

Model year (MY) The year of a vehicle, which may be different from the calendar year when it is sold.

Modified X A method of tire rotation.

Modulation The combination of these two frequencies is referred to as modulation.

Mold-bonded lining A design of disc brake pads where the lining material is molded into holes in the steel backing plate.

Molybdenum disulfide (MOS2) grease Lubrication of moving or sliding components prevents noise from being generated as the parts move over each other. Many vehicle manufacturers recommend Molybdenum disulfide (MOS2) grease.

Momentary switch A type of switch that toggles between on and off.

Mono leaf A leaf spring that uses only one leaf.

Monoblock Blocks are often of the monoblock design, which means that the cylinder, water jacket, main bearing supports (saddles), and oil passages are all cast as one structure for strength and quietness.

Moon roof A moon roof is made of a tinted glass panel that can be either tilted open or completely retracted to operate as an open window in the roof. Most new cars have moon roofs.

Morse type The silent chain type (also known as a flat-link type, or Morse type for its original manufacturer) operates quietly but tends to stretch with use. The metal links themselves do not "stretch" but, instead, the pin bushings at each joint wear, which causes the chain to become longer.

MOSFET Metal oxide semiconductor field-effect transistor; a type of transistor.

MPGe To help consumers compare the energy consumption of electric vehicles with those that run on fossil fuel, the EPA created a miles-per-gallon measurement, called MPGe. This is calculated based on a conversion factor of 33.705 kilowatt-hours of electricity equaling one gallon of gasoline. Therefore, a battery that has a capacity of 100 kWh is equal to the energy of about three gallons of gasoline.

MSI Steering axis inclination (SAI) is also called MacPherson strut inclination (MSI) on a vehicle equipped with McPherson struts.

Mu (μ) The Greek letter that represents the coefficient of friction.

Muffler A muffler is used in the exhaust stream to help quiet the sound of engine combustion.

Mufflers A device that quiets compressor pumping sounds.

Multigroove adjustable pliers Pliers that are capable of grasping a wide range of object sizes; also called water pump pliers or by a popular brand name of Channel Locks®.

Multilayered steel (MLS) gaskets The multilayered steel (MLS) gaskets are constructed in the following manner: 1. Three to five layers of stainless steel sheet are separated by elastomer (rubber) material. 2. The elastomer material is between the layers of the sheet metal and on both surfaces. 3. The multiple layers of metal provide a spring like effect to the gasket, which allows it to keep the combustion chamber sealed.

Multiple-plate clutch The multiple-plate clutch consists of plates, a piston, drum (retainer), and snap ring. Hydraulic pressure acts upon the clutch piston which moves in the drum. The piston movement compresses the plates together to provide either a holding or driving function. When the pressure is released, the piston returns to an unapplied position via a return spring assembly. This entire assembly is commonly known as a clutch pack.

Multiplexing A process of sending multiple signals of information at the same time over a signal wire.

Mutual induction The generation of an electric current due to a changing magnetic field of an adjacent coil.

N.C. Normally closed.

N.O. Normally open.

NASTF The NASTF is a cooperative effort of the automotive service industry, the tool industry, and the original equipment manufacturers to ensure that automotive professionals employed outside of the OEMs have all the information, training, and tools they need to diagnose and repair modern automobiles.

National Lubricating Grease Institute (NLGI) Usually associated with grease. The higher the NLGI number, the firmer the grease. #000 is very fluid whereas #5 is very firm. The consistency most recommended is NLGI #2 (soft).

Natural frequency The frequency where the brake pads tend to vibrate.

Naturally (normally) aspirated An engine that uses atmospheric pressure for its intake charge is called a naturally (normally) aspirated engine.

Naturally aspirated If atmospheric air pressure is used to force the air-fuel mixture into the cylinders, the engine is called naturally aspirated.

Needle rollers A needle bearing is a type of roller bearing that uses smaller rollers called needle rollers. The clearance between the diameter of the straight roller is manufactured into the bearing to provide the proper radial clearance and is not adjustable.

Needle-nose pliers Pliers that are equipped with pointed jaws, which allow use in restricted areas or for small parts.

Negative temperature coefficient (NTC) Usually used in reference to a temperature sensor(coolant or air temperature). As the temperature increases, the resistance of the sensor decreases.

Nernst cell Another name for a conventional oxygen sensor. The Nernst cell is named for Walther Nernst, 1864–1941, a German physicist known for his work in electrochemistry.

Net The paycheck you receive will be for an amount called net earnings and taxes and other deductions will have been taken out from your gross pay.

Network A communications system used to link multiple computers or modules.

Neutral charge An atom that has the same number electrons as protons.

Neutral flame The neutral flame is generally used for welding and burns about one part oxygen to one part acetylene. Adjust the torch until the inner cone is blunt and the feathery edges have disappeared. A typical neutral flame burns at 5900° F (3260° C).

Neutral position This partially open position, also called the neutral position or the fail safe position, is about 16% to 20% open.

Neutral run-up test A test used to help determine the source of a vibration. Engine speed is increased and vibration is measured with the transmission in neutral.

Neutral safety switch An electrical switch that allows the starter to be energized only if the gear selector is in neutral or park.

Neutral In neutral, all of the synchronizer sleeves are centered on their hubs

Newton's laws of motion Newton's first law of motion states that an object at rest tends to stay at rest and an object in motion tends to stay in motion unless acted on by an outside force.

NGV Natural gas vehicle.

Nibs Small V-shaped notches on the side of brake shoes where they rest against the backing plate.

Nickel, cobalt, and aluminum (NCA) Nickel, cobalt, aluminum (NCA) cathode material results in a long battery life and faster charging capability compared to some other types of battery chemistry.

Nickel, manganese, and cobalt (NMC) A NMC battery uses a combination of nickel, manganese and cobalt (NMC) for the cathode material. This cathode material results in slightly lower energy, but is less volatile and can withstand variation in temperature.

Nickel-metal hydride (NiMH) A battery design used for the high-voltage batteries in most hybrid electric vehicles.

Night vision Night vision systems use a camera that is capable of observing objects in the dark to assist the driver while driving at night. The primary night-viewing illumination devices are the headlights.

The night vision option uses a HUD to improve the vision of the driver beyond the scope of the headlights.

NiMH Nickel-metal hydride. A battery design used for the high-voltage batteries in most hybrid electric vehicles.

Nitriding To improve wear resistance, some manufacturers harden the crankshaft journals. Methods used to harden the crankshaft journals includes: Nitriding, where the crankshaft is heated to about 1,000°F (540°C) in a furnace filled with ammonia gas, and then allowed to cool.

Nitrogen oxides (NOx) Nitrogen (N2) and oxygen (O2) molecules are separated into individual atoms of nitrogen and oxygen during the combustion process. These molecules then bond to form NOx (NO, NO2). When combustion flame front temperatures exceed 2,500°F (1,370°C), NOx is formed inside the cylinder, which is then discharged into the atmosphere from the tailpipe.

Nitrogen (N_2) Nitrogen gas is used to inflate tires and is used to prevent moisture and oxygen inside a tire where it can increase the chances of rust or corrosion.

NLGI National Lubricating Grease Institute. Usually associated with grease. The higher the NLGI number, the firmer the grease. #000 is very fluid whereas #5 is very firm. The consistency most recommended is NLGI #2 (soft).

Node A module and computer that is part of a communications network.

Noid light Designed to electrically replace the injector in the circuit and to flash if the injector circuit is working correctly.

Noise-reducing tire The purpose of a noise reducing tire is to eliminate noise in the 130 to 240 Hz range that would be normally covered up by normal engine noise in a vehicle with an internal combustion engine. The noise reduction is accomplished by adding acoustical foam to the inside of a tire.

Non-asbestos organic (NAO) Brake pads and linings that use synthetic material, such as aramid fibers, instead of steel are usually referred to as: 1. non-asbestos 2. non-asbestos organic (NAO) and 3. non-asbestos synthetic (NAS). These friction materials are often called ceramic in the American aftermarket because they include ceramic fibers, which are usually potassium titanite.

Non-asbestos synthetic (NAS) Brake pads and linings that use synthetic material, such as aramid fibers, instead of steel are usually referred to as: 1. non-asbestos 2. non-asbestos organic (NAO) and 3. non-asbestos synthetic (NAS). These friction materials are often called ceramic in the American aftermarket because they include ceramic fibers, which are usually potassium titanite.

Non-condensable gas (NCG) Gases, such as air in an A/C system, that do not readily change to a liquid state as the refrigerant does.

Non-condensable gases (NCG) Gases, such as air in an A/C system, that do not readily change to a liquid state as the refrigerant does.

Nonhunting gear sets Nonhunting gear sets are gear sets with final drive ratios expressible as a whole number

Non-hygroscopic Brake fluid, such as DOT 5 that does not absorb moisture from the air.

Non-load-carrying ball joint If the coil spring is attached to the top of the upper control arm, then the upper ball joint is carrying the weight of the vehicle and is called the load-carrying ball joint.

Non-methane organic gases (NMOG) Non-methane organic gases (NMOG) and NOx are combined under one limit, meaning that the HC and NOx have to be both controlled to meet these standards.

Nonprincipal end The nonprincipal end of the engine is opposite the principal end and is generally referred to as the front of the engine, where the accessory belts are used.

Non-servo brakes A drum brake design where the primary lining (forward facing) does not control or transmit a force to the secondary (rearward facing) brake shoe.

Non-Verbal Communications Not involving or using words to communicate. Examples of are hand gestures, head nodding, and body position.

Nonvolatile RAM Nonvolatile RAM memory can retain its information even when the battery is disconnected.

Nonvolatile random access memory (NVRAM) Nonvolatile RAM memory can retain its information even when the battery is disconnected. One use for this type of RAM is the storage of odometer information.

No-retorque-type gaskets No-retorque-type gaskets, mean the cylinder head bolts do not have to be retorqued after the engine has run. New gaskets do not contain asbestos.

Normal operating temperature Normal operating temperature is the temperature at which the upper radiator hose is hot and pressurized.

NPN transistor A type of transistor that has the P-type material in the base and the N-type material is used for the emitter and collector.

NTC Negative temperature coefficient. Usually used in reference to a temperature sensor (coolant or air temperature). As the temperature increases, the resistance of the sensor decreases.

N-type material Silicon or germanium doped with phosphorus, arsenic, or antimony.

Nut splitter A hand tool designed to break a nut that is rusted onto a bolt or stud.

NVH Abbreviation for noise, vibration and harshness.

OAD Overrunning alternator dampener.

OAP Overrunning alternator pulley

OBD-II The engine, as well as the engine management systems can test itself, for proper operation and alert the driver if a fault is detected. The warning lamp is called the malfunction indicator light (MIL) and is labeled “Check Engine” or “Service Engine Soon.” The on-board diagnostic system is currently in the second generation and is called OBD-II.

Occupant detection system (ODS) An airbag system that includes a sensor in the passenger seat used to detect whether or not a passenger is seated in the passenger side and the weight range of that passenger.

Occupational Safety and Health Administration (OSHA) OSHA is the main federal agency responsible for enforcement of workplace safety and health legislation.

Octane rating The measurement of a gasoline’s ability to resist engine knock. The higher the octane rating, the less prone the gasoline is to cause engine knock (detonation).

OEM (Original Equipment Manufacturers) OEM (Original Equipment Manufacturer) parts are manufactured by the same company that produced the original part used in assembly of the vehicle.

Offset The distance the center section (mounting pad) is offset from the centerline of the wheel.

Ohm’s Law An electrical law that requires 1 volt to push 1 ampere through 1 ohm of resistance.

Ohmmeter An electrical test instrument used to measure ohms (unit of electrical resistance).

Ohms The unit of electrical resistance. Named for George Simon Ohm.

Oil control ring Piston rings are classified into two types, one type is one oil control ring, located below the compression rings.

Oil control valve (OCV) The camshaft position actuator oil control valve (OCV) directs oil from the oil feed in the head to the appropriate camshaft position actuator oil passages.

Oil filter An engine-driven oil pump forces the oil under pressure through an oil filter, then to passages in the block and head called oil galleries, and then to all of the moving parts.

Oil gallery plugs After oil holes are drilled, the unneeded open ends may be capped by pipe plugs, steel balls, or cup-type soft plugs, often called oil gallery plugs.

Oil gallery An oil pump which is driven by the engine, forces the oil through the oil filter and then into passages in the crankshaft and block.

Oil pan All engines need a supply of lubricating oil to reduce friction and help to cool the engine. Most engines are equipped with an oil pan, also called an oil sump, containing 3 to 7 quarts (liters) of oil.

Oil pump An engine-driven oil pump forces the oil under pressure through an oil filter, then to passages in the block and head called oil galleries, and then to all of the moving parts.

Oil sump An engine-driven oil pump forces the oil under pressure through an oil filter, then to passages in the block and head called oil galleries, and then to all of the moving parts.

oil trap Many A/C compressors use an oil trap to help the oil in the compressor this method is not as efficient as it has been in the past when used with older systems.

OL Overload or over limit.

On-board diagnosis (OBD) During the 1980s, most manufacturers began equipping their vehicles with full-function control systems capable of alerting the driver of a malfunction and of allowing the technician to retrieve codes that identify circuit faults. These early diagnostic systems were meant to reduce emissions and speed up vehicle repair. The automotive industry calls these systems On-Board Diagnostics (OBDs).

Onboard refueling vapor recovery (ORVR) Onboard refueling vapor recovery (ORVR) systems have been developed to reduce evaporative emissions during refueling. These systems add components to the filler neck and the tank.

One-pedal driving One pedal driving means that for normal driving, the driver only needs to use the accelerator pedal to accelerate and deaccelerate.

Oneway clutch Another common type of automatic transmission device is the one-way clutch (OWC), or overrunning clutch. Like a transmission band, a one-way clutch is always a holding device. One-way clutches are either roller or sprag clutches, although the roller clutch is more common.

One-way valve A one-way valve allows fluid to flow in one direction.

OnStar OnStar does not display the location of the vehicle to the driver unless the vehicle is also equipped with a navigation system. Unlike most navigation systems, the OnStar system requires a monthly fee. The driver interface unit is a group of three buttons mounted on the inside rearview mirror and a hands-free cellular telephone.

On-the-job training (OJT) Training that occurs in the actual work environment. For Technicians training occurs while working on the vehicle.

Op-amps Used in circuits to control and simplify digital signals.

Open circuit voltage Voltage measured without the circuit in operation.

Open circuit Any circuit that is not complete and in which no current flows.

Open loop When the PCM alone is determining the amount of fuel needed, it is called open-loop operation.

Open-end wrench A wrench with jaws having a fixed width of opening at one or both ends of the handle. An open-end wrench can be easily placed on a bolt or nut with an angle of 15 degrees, which allows the wrench to be flipped over and used again to continue to rotate the fastener.

Opposite-phase steering A type of four-wheel steering when the front wheels and rear wheels are steered in the opposite direction.

Organic acid technology (OAT) Antifreeze coolant contains ethylene glycol, but does not contain silicates or phosphates. This type of coolant is usually orange in color and was first developed by Havoline (called DEX-COOL) and used in General Motors vehicles starting in 1996.

Original equipment (OE) Parts at a new vehicle dealership come either directly from the vehicle manufacturer or a regional dealership. Original equipment parts, abbreviated OE, are generally of the highest quality because they have to meet performance and durability standards not required of replacement parts manufacturers.

Oscilloscope A visual display of electrical waves on a fluorescent screen or cathode ray tube.

OSHA Occupational Safety and Health Administration. OSHA is the main federal agency responsible for enforcement of workplace safety and health legislation.

Out-of-round A fault with a brake drum, which is not perfectly round.

Output drivers There are two basic types of output drivers. They are Low-side drivers and High-side drivers.

Output member The drive member of a planetary gear set is called the input member, the held member, the reaction member, and the driven member, the output member.

Output shaft The input shaft is splined to the clutch disc and is also referred to as the main gear, clutch gear, or main drive pinion assembly. The main shaft, also called the output shaft, is splined at the end and transmits engine torque to the drive shaft (propeller shaft) through a yoke and universal shaft.

Output speed sensor (OSS) This speed sensor, also called the vehicle speed (VS) sensor, is used by the PCM for speedometer and cruise control operation as well as for transmission/transaxle operation and shift-related fault detection.

Outside air temperature (OAT) sensor The outside air temperature (OAT) sensor, also called the ambient temperature sensor, measures outside air temperature and is often mounted at the radiator shroud or in the area behind the front grill.

Outside air Outside air is often called fresh air.

Outside Purchase An outside purchase happens when a part is a non-stocking part and ordered from an outside supplier.

over the air (OTA) The process of updating electronic modules using cellular or Wi-Fi system.

Overcenter adjustment Gear mesh preload is a measurement of how much turning force must be applied to the input shaft to overcome the resistance of the sector gear and move it. Gear mesh preload is usually measured in a 90-degree turn across the center of the input shaft movement. General Motors calls this adjustment the overcenter adjustment.

Overdrive In a transmission or drive axle, when the input shaft turns slower than the output shaft. A gear ratio of 0.87:1 is considered to be an overdrive gear ratio because only 0.87 turns of the input shaft will result in 1 full turn of the output shaft.

Overhead camshaft (OHC) Newer engine designs feature overhead camshafts (OHC), called single overhead camshaft (SOHC) designs and engines that use two overhead camshafts per bank of cylinders called double overhead camshaft (DOHC) designs. The placement of the camshaft results in better flow of intake air into and exhaust out of the engine.

Overhead valve (OHV) By the 1950s, most engine designs placed the valves in the cylinder head. This is called an overhead valve or OHV design.

Overlay Corrosion results in bearing journal wear as the bearing is eroded by the acids. Many of the copper-lead bearings have an overlay, or third layer, of metal. This overlay is usually of babbitt. Babbitt-overlayed bearings have high fatigue strength, good conformity, good embeddability, and good corrosion resistance.

Overrunning clutch A mechanical coupling device that allows torque to be transmitted in one direction of rotation, but freewheels when turned in the opposite direction. Also known as a *one-way clutch*.

Oversize (OS) stems Some domestic vehicle manufacturers that have integral valve guides in their engines recommend reaming worn valve guides and installing new valves with oversize (OS) stems. When a valve guide is worn, the valve stem is also likely to be worn. In this case, new valves are required. If new valves are used, they can just as well have oversize stems.

Oversteering Oversteering is when the rear of the vehicle tends to move outward or breaks loose, resulting in the vehicle spinning out of control. This condition is also called loose. If the condition is detected during a left turn, the ESC system would apply the right front brake to bring the vehicle back under control.

Over-travel spring A spring used as part of the self-adjusting components that allow normal operation even if the star wheel adjuster does not move.

Owner's manual The owner's manual is the instructional booklet that comes with every new vehicle and includes important information.

Oxides of nitrogen (NOx) A primary emission produced in the combustion chamber under high temperatures when nitrogen combines with oxygen. Oxides of nitrogen contribute to the formation of smog (ground level ozone [O3]) when combined with HC and sunlight.

Oxidizing flame The oxidizing flame is used for brazing and is obtained by opening the oxygen valve slightly more than the neutral flame. The inner cone gets shorter and pointed and it becomes somewhat purple in color. Flame temperature is about 6300° F (3482° C).

Oxygen (O2) Oxygen (O2) is an element that composes 21% of air.

Oxygen sensors (O2S) Automotive computer systems use a sensor in the exhaust system to measure the oxygen content of the exhaust. These sensors are called oxygen sensors (O2S).

Oxygen storage capacity (OSC) The converters used on these vehicles have oxygen storage capacity (OSC), due mostly to the cerium coating in the catalyst rather than the precious metals used. The converter stores, then releases, the oxygen during normal reduction and oxidation of the exhaust gases, smoothing out the variations in oxygen being released.

Oxygenated fuels Fuels such as ETBE or MTBE that contain extra oxygen molecules to promote cleaner burning. Oxygenated fuels are used as gasoline additives to reduce CO emissions.

Ozone (Health and Environmental Concerns) Ozone is composed of three atoms of oxygen and is abbreviated O3. In high concentrations it can be a lung and respiratory irritant.

Ozone (Vehicle Emissions Standards and Testing) Oxygen rich (O3) gas created by sunlight reaction with un-burned hydrocarbons (HC) and oxides of nitrogen (NOx); also called smog.

Ozone depletion potential (ODP) The amount of effect that certain chemicals have on the ozone layer.

Ozone-depleting substances (ODS) Depletion of the earth's upper ozone layer due to the release of man-made chemicals threatens human health and damages plant life. Certain manmade chemicals used in refrigeration, air conditioning, fire and explosion prevention, and as solvents can trigger reactions in the atmosphere that destroy the ozone layer. Ozone-depleting substances (ODS) include chlorofluorocarbons (CFCs), hydro-chlorofluorocarbons (HCFCs), halons and methyl bromide.

Pacific fuse element A type of automotive fuse.

Pad wear indicators A metal strap or notch in the disc brake pad to indicate that the pads are worn to the point of needing replacement.

PAG (polyalkylene glycol) PAG (polyalkylene glycol) oils are used in most R-134a refrigerant systems.

Paired cylinder Each end of the secondary winding is connected to a cylinder exactly opposite the other in the firing order, which is called a companion (paired) cylinder. This means that both spark plugs fire at the same time

Pal nut Jam nuts screw on top of a regular nut and jam against the regular nut to prevent loosening. A jam nut is so called because of its intended use, rather than a special design.Some jam nuts are thinner than a standard nut. Jam nuts are also called pal nuts .

Palladium The converter substrate contains small amounts of rhodium, palladium, and platinum. These elements act as catalysts. As mentioned, a catalyst is an element that starts a chemical reaction without becoming a part of, or being consumed in, the process.

Pancake An engine arranged for compactness by stacking cylinders one above another horizontally or side by side. This style of engine is used in Porsche and Subaru engines, and is often called a boxer engine.

Panhard rod A horizontal steel rod or bar attached to the rear axle housing at one end and the frame at the other to keep the center of the body directly above the center of the rear axle during cornering and suspension motions. Also called a *track rod.*

Paper test Hold a piece of paper or a 3 × 5 index card (even a dollar bill works) within 1 inch (2.5 cm) of the tailpipe with the engine running at idle. The paper should blow out evenly without "puffing." If the paper is drawn toward the tailpipe at times, the exhaust valves in one or more cylinders could be burned.

Parallel circuit An electrical circuit with more than one path from the power side to the ground side. Has more than one branch or leg.

Parallel clutch A clutch design used in a dual clutch automatic where the clutches rearranged side-by-side.

Parallel flow system In the parallel flow system, coolant flows into the block under pressure and then crosses the head gasket to the head through main coolant passages beside each cylinder.

Parallelism A measurement of a brake rotor to determine that both sides of the rotors are perfectly parallel.

Parallelogram linkage A geometric box shape where opposite sides are parallel (equal distance apart). A type of steering linkage used with a conventional steering gear that uses a pitman arm, center link, idler arm and tie rods.

Parameter identification (PID) When using a scan tool, powertrain data is listed using an ID and its current value or status. The specific piece of data is called the parameter identification (PID).

Parasitic load test An electrical test that measures how much current (amperes) is draining from the battery with the ignition off and all electrical loads off.

Parking assist systems The parking-assist system is used to help drivers avoid contact with another object while moving slowly. When backing up at speed of less than 5 MPH (8 km/h), the system constantly monitors for objects located around the vehicle.

Partially nonhunting gear sets Partially nonhunting gear sets are gear sets with final drive ratios expressible as a reducible fraction not equaling a whole number.

Particulate matter (PM) Also called soot and an emission from diesel engines.

Partitions Separations between the cells of a battery. Partitions are made of the same material as that of the outside case of the battery.

Parts Bulletins Parts Bulletins inform the parts store personnel about technical changes to the part.

Parts counter person A parts counter person often learns job skills by on-the-job training. A good parts counter person must be able to greet and easily talk to customers and technicians. A parts counter person must also have computer skills and the willingness to help others

Part-time employment Employment that is less than forty hours per week.

Pascal's law A law of hydraulics named for the person who developed it, Blaise Pascal (1632–1662)

PASS A word used to help remember how to use a fire extinguisher; pull pin, aim, squeeze the lever, and sweep the nozzle from side to side.

Passenger presence system (PPS) An airbag system that includes a sensor in the passenger seat used to detect whether or not a passenger is seated in the passenger side and the weight range of that passenger.

Passivation Passivation is a chemical reaction that takes place between coolant additives and the metal that it protects.

Passive balancing Passive balancing is achieved by having energy drawn from the most charged cell and dissipated as heat, usually through resistors. Passive balancing allows the stack to act as if every cell has the same capacity as the weakest cell. Using a relatively low current, it drains a small amount of energy from high SOC cells during the charging cycle so that all cells charge to their maximum state-of-charge (SOC).

Passive entry, passive starting (PEPS) A remote fob that allows entry to the vehicle is within a certain distance of the vehicle and allows the starting.

Passive wheel speed sensor A passive wheel speed sensor generates its own output signal and can operate without an outside voltage being applied. Passive wheel speed sensors are often called variable reluctance (VR)–type sensor, which uses a magnetic core surrounded by coil windings.

Pass-through device A pass-through device or API serves as a connection point that makes all the hardware look the same, and allows the computer with the reprogramming software to communicate with the vehicles control module through the data link connector (DLC).

Pattern bending Means measuring and comparing the old exhaust pipe to make a new one. This may be necessary when making a pipe for an older or low production vehicle for which no program card exists.

Pawl A lever for engaging in a notch. Used to rotate the notched star wheel on self-adjusting brakes.

PCV valve Regulates the flow of gases created in the crankcase of a running engine, which are routed back into the intake manifold. The engine will then draw these gases into the combustion chamber where they are burned to help prevent the release of the gases into the atmosphere.

Peak inverse voltage (PIV) The rating of resistance to reverse-bias voltage. Also called peak reverse voltage (PRV).

Peak reverse voltage (PRV) The rating of resistance to reverse-bias voltage is called the peak inverse voltage (PIV) rating, or the peak reverse voltage (PRV) rating.

Peak-and-hold A method for regulating the current flow through electronic fuel injectors. Supplies higher current necessary to energize the injector, then drops to a lower level just enough to keep the injector energized.

Pedal free play Pedal free play is the distance the brake pedal travels before the primary piston in the master cylinder moves.

Pedal height Proper brake pedal height is important for the proper operation of the stop (brake) light switch. If the pedal is not correct, the pushrod may be in too far forward, preventing the master cylinder cups from uncovering the compensation port. If the pedal is too high, the free play is excessive.

Pedal ratio The mechanical advantage of the brake pedal due to the location of the fulcrum and the length of the pedal arm.

Peltier Effect A French scientist Peltier found that electrons moving through a solid can carry heat from one side of the material to the other side. This effect is called the Peltier effect.

Pending code Any code(s) that are displayed when the MIL is not on is called a pending code.

Penetrating oil A thin oil that is designed to penetrate through rust and provide lubrication for the threads of a fastener.

Penetration test The American Society for Testing Materials (ASTM) specifies the consistency of grease using a penetration test. The National Lubricating Grease Institute (NLGI) uses the penetration test as a guide to assign the grease a number. Low numbers are very fluid and higher numbers are more firm or hard.

Percentage Percentage is the relationship of a value or number out of 100.

Perimeter frame A steel structure for a vehicle that supports the body of the vehicle under the sides, as well as the front and rear.

Peripheral pump A turbine pump is the most common because it tends to be less noisy. Sometimes called turbine, peripheral, and side-channel, these units use an impeller that accelerates the fuel particles before actually discharging them into a tract where they generate pressure via pulse exchange.

Permanently Engaged (PE) Starter A permanently engaged starter delivers the quickest and quietest restart times of all starter motor-based systems. In this system, the starter and flywheel gears are permanently connected, so there are no concerns with gear engagement and disengagement.

Permeability The measure of how well a material conducts magnetic lines of force.

Personal protective equipment (PPE) Personal protective equipment that can include gloves, safety glasses, and other items.

pH A measure of the acidity or alkalinity of a material. A pH of 7 is neutral, higher than 7 is alkaline, and lower than 7 is acidic.

Phone as a Key (PAAK) Many hybrid electric and electric vehicles, as well as some regular (ICE) vehicles can be controlled using a smart phone application (app). This control of the vehicle, including remote start from the smart phone, is referred to as Phone as a Key (PAAK).

Phosphate hybrid organic acid technology (PHOAT) Phosphate hybrid organic acid technology (PHOAT) is used in Mazda-based Fords (2008+), same as Mazda FL-22, and is ethylene glycol based. This coolant is available in a 55% coolant/45% water premix.

Photodiodes A type of diode used as a sun-load sensor. Connected in reverse bias, the current flow is proportional to the sun load.

Photoelectricity When certain metals are exposed to light, some of the light energy is transferred to the free electrons of the metal. This excess energy breaks the electrons loose from the surface of the metal. They can then be collected and made to flow in a conductor which is called photoelectricity.

Photons Light is emitted form an LED by the release of energy in the form of photons.

Photoresistor A semiconductor that changes in resistance with the presence or absence of light. Dark is high resistance and light is low resistance.

Phototransistor An electronic device that can detect light and turn on or off. Used in some suspension height sensors.

Piezoelectricity The principle by which certain crystals become electrically charged when pressure is applied.

Piezoresistivity There are four resistors attached to the silicon wafer, which changes in resistance when strain is applied to the wafer. This change in resistance due to strain is called piezoresistivity. The resistors are electrically connected to a Wheatstone bridge circuit and then to a differential amplifier, which creates a voltage in proportion to the vacuum applied.

Pillars The roof of a vehicle is supported by pillars and they are labeled A, B, C, and D from the front to the rear of the vehicle. All vehicles have an A pillar at the windshield but many, such as a hardtop, do not have a B pillar. Station wagons and sport utility vehicles (SUVs) often have a D pillar at the rear of the vehicle.

Pilot bearing A pilot bearing (or bushing) that supports the front of the transmission input shaft.

Pin bushings The small roller bearings used in a universal joint.

Pinch bolt A bolt used to retain a ball joint in some designs of suspensions.

Ping Secondary rapid burning of the last 3 to 5% of the air-fuel mixture in the combustion chamber causes a second flame front that collides with the first flame front causing a knock noise. Also called *detonation* or *spark knock*.

Pinion gear A small gear on the end of the starter drive which rotates the engine flywheel ring gear for starting.

Pinion shaft A pinion shaft passes through the two pinion gears in the case. In mesh with the pinion gears are two side gears that are splined to the inner ends of the axles.

Pinion-mounted electric power steering system (P-EPS) While not directly mounted on the column itself, another type of electric power steering is the pinion-mounted electric power steering system (P-EPS) system. This system has the assist motor connected to the pinion shaft of the rack and-pinion steering gear.

Pin-slider caliper A disc brake caliper design that uses guide pins and is able to move slightly during a brake application.

Pipe adapter A pipe adapter is used to connect non-standard exhaust components to existing OEM components like the one used to connect to the catalytic converter to the existing exhaust systems or connecting one size pipe to another.

Piston compressors A piston compressors is a positive-displacement compressor that uses pistons driven by a crankshaft. Most older automotive compressors used a crankshaft, similar to a small gasoline engine, and a reciprocating-piston type. Newer piston compressors use a swash or wobble plate.

Piston pin The piston is attached to the connecting rod with a piston pin, also called a wrist pin. The piston pin is allowed to have a rocking movement because of a swivel joint at the piston end of the connecting rod.

Piston ring compressor The piston ring compressor is then put on the piston to hold the rings in their grooves.

Piston ring expander Installing the compression rings requires the use of a piston ring expander tool that will only open the ring gap enough to slip the ring on the piston.

Piston rings Piston rings seal the small space between the piston and cylinder wall, keeping the pressure above the piston.

Piston stops Metal tangs next to drum brake wheel cylinders used to prevent cylinder pistons from coming out of their bores when the brake lining is removed.

Piston stroke A piston stroke is a oneway piston movement either from top to bottom or bottom to top of the cylinder. During one stroke, the crankshaft rotates 180 degrees (1/2 revolution).

Piston A solid cylinder or disk that fits snugly into a larger cylinder and moves under fluid pressure. The piston forms a movable bottom to the combustion chamber.

Pitch The pitch of a threaded fastener refers to the number of threads per inch.

Pitman arm A short lever arm that is splined to the steering gear cross shaft. It transmits the steering force from the cross shaft to the steering linkage.

Pitman shaft As the steering wheel is turned, the movement is transmitted through the steering gear to an arm attached to the bottom end of the pitman shaft. This arm is called the pitman arm. Whenever the steering wheel is turned, the pitman arm moves.

Placard cold inflation pressure The term placard cold inflation pressure is used in service information to indicate the specified tire inflation pressure.

Plain bearing Most engine bearings are one of two types which are plain bearing and sleeve bearing.

Planar In 1998, Bosch introduced a wide-band oxygen sensor that is flat and thin (1.5 mm or 0.006 inch), known as a planar design, and not in the shape of a thimble, as previously constructed. Now several manufacturers produce a similar planar design wide-band oxygen sensor. Its thin design makes it easier to heat than older styles of oxygen sensors and, as a result, it can achieve closed loop in less than 10 seconds.

Planet carrier The part of a planetary gearset that houses the planet pinions.

Planet pinions The planet pinion gears rotate around the sun gear, like the planets around the sun, and are attached by a planet carrier.

Plateau honing This plateau surface is achieved by first using a coarse honing stone followed by a smooth stone to achieve the desired surface. The process of using a course and fine stone is called plateau honing.

Platform The platform of a vehicle includes the basic structure (frame and/or major body panels), as well as, the basic steering and suspension components. One platform may be the basis for several different brand vehicles.

Platinum spark plugs Platinum spark plugs have a small amount of the precious metal platinum welded onto the end of the center electrode, as well as on the ground or side electrode.

Platinum The converter substrate contains small amounts of rhodium, palladium, and platinum. These elements act as catalysts. As mentioned, a catalyst is an element that starts a chemical reaction without becoming a part of, or being consumed in, the process.

Plenum A chamber, located between the throttle body and the runners of the intake manifold, used to distribute the intake charge more evenly and efficiently.

Plug-in hybrid electric vehicle (PHEV) A plug-in hybrid electric vehicle (PHEV) is a vehicle that is designed to be plugged into an electrical outlet at night to charge the batteries.

Plunge joint An inner constant velocity joint that is able to move in and out and transmit torque while the vehicle suspension moves up and down over bumps.

Ply steer A term used to describe why a tire can cause a pulling condition based on the angle of the cords of the belt layers.

PNP transistor A type of transistor that used N-type material for the base and P-type material for the emitter and collector.

POE (polyol ester) POE (polyol ester) (ester) oils are used in a few R-134a systems, and either ester or PAG oils are used in R-12 systems that have been retrofitted to R-134a.

Point of purchase (POP) Displays are also often built near the cash register as a point of purchase (POP) display, so that customers notice the product when they pay.

Polarity The condition of being positive or negative in relation to a magnetic pole.

Pole shoes The metal part of the field coils in a starter motor.

Pole The point where magnetic lines of force enter or leave a magnet.

Poles The point where magnetic lines of force enter or leave a magnet.

Polyalphaolefin (PAO) Lubrication of moving or sliding components prevents noise from being generated as the parts move over each other. Many vehicle manufacturers recommend Polyalphaolefin (PAO).

Polyglycol A term used to describe brake fluid.

Polymer electrolyte fuel cell (PEFC) Another term for Proton Exchange Membrane fuel cell. See *PEM*.

Pop rivet A type of fastener that uses a rivet gun to pull out the rivet until the end deforms and thereby creating a light clamping form.

Poppet valve Automotive engine valves are of a poppet valve design. The term poppet refers to the shape of the valve and their operation in automotive engines.

Porous lead Lead with many small holes to make a surface porous for use in battery negative plates; the chemical symbol for lead is Pb.

Porsche Doppelkupplung (PDK) Another term used to describe a dual-clutch automatic transmission/transaxle used in Porsche vehicles.

Port fuel-injection A port fuel-injection design uses a nozzle for each cylinder and the fuel is squirted into the intake manifold about 2 to 3 inches (70 to 100 mm) from the intake valve.

Port The part of the intake or exhaust system passage that is cast in the cylinder head is called a port.

Portable crane A piece of shop equipment that is used to lift and move heavy pieces of equipment, such as an engine.

Porting (relieving) Redirecting flow that is large enough to handle the flow is called porting or relieving.

Positive crankcase ventilation (PCV) System used to prevent corrosive blow-by gases (by-products of combustion) in the crankcase from entering the atmosphere.

Positive displacement pumps A type of pump where everything that enters the pumps, leaves the pump.

Positive displacement The roots supercharger was patented in 1860 as a type of water pump to be used in mines. Later, it was used to move air and is used today on two-stroke-cycle Detroit diesel engines and other supercharged engines. The roots-type supercharger is called a positive displacement design, because all of the air that enters is forced through the unit.

Positive rotators A type of rotator that causes the valve to rotate in a controlled manner as it is opened.

Positive slip Traction control allows an ABS to control wheel spin during acceleration. When tires lose traction during acceleration, it is called positive slip.

Positive temperature coefficient (PTC) Usually used in reference to a conductor or electronic circuit breaker. As the temperature increases, the electrical resistance also increases.

Positive twist ring A positive twist ring gives the same wall contact as the taper face ring. It also provides a line contact seal on the bottom side of the groove. Sometimes, a twist and a taper face are used on the same compression ring.

Potential energy the energy possessed by a body by virtue of its position relative to others, stresses within itself, electric charge, and other factors. Potential energy if it is capable of being changed to useful energy, such as the potential energy stored in a battery or a vehicle at the top of a hill.

Potentiometer A 3-terminal variable resistor that varies the voltage drop in a circuit.

Pouch cell Pouch design HV battery uses laminated architecture in a bag referred to as pouch cell. It is light and cost-effective, but exposure to humidity and high temperature can shorten its life.

Pour point Oil must not be too thick at low temperatures to allow the engine to start. The lowest temperature at which oil will pour is called its pour point.

Power balance test The purpose of a cylinder power balance test is to determine if all cylinders are contributing power equally. It determines this by shorting out one cylinder at a time.

Power bleeding Also called pressure bleeding.

Power chamber The enclosure of a vacuum brake booster assembly which is separated into the vacuum side and the atmospheric air pressure side by a flexible diaphragm.

Power path The path electricity travels between the source, usually the battery, and the load.

Power source In electrical terms the battery or generator (alternator).

Power steering control module (PSCM) The power steering control module (PSCM) and the power steering motor are serviced as an assembly and are serviced separately from the steering column assembly

Power steering pressure (PSP) A pressure switch, known as the power steering pressure (PSP) switch, transmits an electronic signal to the powertrain control module (PCM) when the pressure in the system is high enough to increase the load on the engine. In response to the PSP switch signal, the PCM increases the engine idle speed to prevent stalling.

Power windows Most power window systems use permanent magnet (PM) electric motors. It is possible to run a PM motor in the reverse direction by reversing the polarity of the two wires going to the motor.

Power The rate of doing work, measured in horsepower as kilowatts. In electrical terms, is amperes x volts (Power = $I \times E$).

Powertrain control module (PCM) The on-board computer that controls both the engine management and transmission functions of the vehicle.

Powertrain mounts A part of the vehicle that holds the engine in place to the frame. Broken powertrain mounts can cause stress on the exhaust system to wear and even cause components to break.

PPE Personal protective equipment, which can include gloves, safety glasses, and other items.

PPO Vegetable oil is a triglyceride with a glycerin component joining three hydrocarbon chains of 16 to 18 carbon atoms each, called straight vegetable oil (SVO). Other terms used when describing vegetable oil include: 1. Pure plant oil (PPO)—a term most often used in Europe to describe SVO. 2. Waste vegetable oil (WVO)—this oil could include animal or fish oils from cooking. 3. Used cooking oil (UCO)—a term used when the oil may or may not be pure vegetable oil

Prealignment checks As part of the prealignment checks check all the tires for proper inflation pressures. Tires should be approximately the same size and tread depth, and the recommended size for the vehicle. Check the wheel bearings for proper adjustment.

Precision insert-type bearing shells Modern automotive engines use precision insert-type bearing shells, sometimes called half-shell bearings. The bearing is manufactured to very close tolerance so that it will fit correctly in each application.

Preconverter Some vehicles have used a small, quick heating oxidation converter, called a preconverter or a pup (mini) converter, that connects directly to the exhaust manifold outlet.

Preloaded clutch Preloaded clutches use two mechanisms to accomplish this action. First, a coil, Belleville, or leaf spring applies a force against the two side gears. Second, a multidisc clutch pack or cones lie behind one or both of the side gears. Vehicle manufacturers refer to these differentials using various brand names, such as Positive Traction, Sure-Grip, Anti-Spin, and Traction-Lok.

Pressure bleeding A method used to bleed air out of a brake hydraulic system using compressed air above the master cylinder reservoir.

Pressure control solenoids Pressure control solenoids is a type of electronic pressure regulation.

Pressure control valve (PCV) A fuel pump and a low-cost, high-performance bypass regulator are used within the appropriate fuel sender. They supply a pressure somewhat higher than the required rail set pressure to accommodate dynamic line and filter pressure losses. Electronic pump speed control is accomplished using a smart regulator as an integral flow sensor. A pressure control valve (PCV) may also be used and can readily reconfigure an existing design fuel sender into a returnless sender.

Pressure control Pressure control (PC) is a type of electronic pressure regulation.

Pressure decay stage A stage during ABS operation where the pressure of the brake fluid at a wheel brake is reduced.

Pressure differential A difference in pressure from one brake circuit to another.

Pressure dump stage The fluid is usually routed into a spring-loaded or pressurized storage reservoir (called an accumulator) so it can be reused as needed. Releasing pressure in the brake circuit allows the brake to loosen its grip so the wheel can speed up and regain traction. This is called: pressure reduction stage, pressure release stage, pressure decay stage, or pressure dump stage.

Pressure feedback EGR (PFE) sensor Some later-model Ford EGR systems, however, use a feedback signal provided by an EGR exhaust back pressure sensor that converts the exhaust back pressure to a voltage signal. This sensor is called a pressure feedback EGR (PFE) sensor.

Pressure holding stage A stage during ABS operation where the pressure of the brake fluid at a wheel brake is held at the correct level.

Pressure increase stage A stage during ABS operation where the pressure of the brake fluid at a wheel brake is increasing due to a driver brake application.

Pressure plate A clutch assembly consists of a clutch disc that is splined to the input shaft of the transmission/transaxle. When the driver depresses the clutch pedal, a throw-out bearing (release bearing) is forced against the fingers of the pressure plate.

Pressure reduction stage The fluid is usually routed into a spring-loaded or pressurized storage reservoir (called an accumulator) so it can be reused as needed. Releasing pressure in the brake circuit allows the brake to loosen its grip so the wheel can speed up and regain traction. This is called: pressure reduction stage, pressure release stage, pressure decay stage, or pressure dump stage.

Pressure regulating valve A valve that limits the pressure of the oil pump.

Pressure regulator valve Transmission oil pumps are capable of creating an excessive amount of pressure quickly; therefore, every transmission uses a pressure regulator valve, or pressure control valve, to control hydraulic pressure.

Pressure release stage The release and isolation solenoids are then closed and the additional solenoid energized, so pressure can be reapplied to the brake from the master cylinder or accumulator to reapply the brake. This is called the pressure increase stage.

Pressure transducer A pressure transducer can be used in the low- and/or high-pressure refrigerant line. The transducer converts the system pressure into an electrical signal that allows the ECM to monitor pressure.

Pressure vent valve (PVV) A valve located in the fuel tank to prevent over-pressure due to the thermal expansion of the fuel.

Pressure A force applied to a surface divided by its area.

Pressure-relief valve To handle the excess pressure in a power steering system, a pressure-relief passage runs from a point near the pressure hose fitting to the spring end of the modulator valve.

Pretensioners An explosive devices used to remove the slack from a safety belt when an airbag is deployed.

Prevailing torque nut A special design of nut fastener that is deformed slightly or has other properties that permit the nut to remain attached to the fastener without loosening.

Preventative maintenance (PM) Preventative maintenance (PM) means periodic service work performed on a vehicle that will help keep it functioning correctly for a long time.

Primary ignition circuit The ignition components that regulate the current in the coil primary winding by turning it on and off are known collectively as the primary ignition circuit.

Primary oil pressure (POP) The fluid pressure applied to the primary pulley in a CVT transmission/transaxle.

Primary pressure sensor (PPS) The sensor used to measure the fluid pressure applied to the primary pulley in a CVT transmission/transaxle.

Primary shoe A brake shoe installed facing the front of the vehicle.

Primary vibration When pistons move up and down in the cylinders, they create a primary vibration, which is a strong low-frequency vibration.

Principal end The end of the engine that the flywheel is attached to.

Program card A program card lists the length and diameter of the pipe, the distance between the center of the bends, and the rotation and depth of the bends in degrees. There may also be remarks that describe bending instructions for peculiar applications. Using this information, the technician can make a pipe identical to the one which was originally installed by the vehicle manufacturer. The number of the program card is found by looking up the make, model, year and engine in the card catalog. There are separate cards for each pipe in the exhaust system.

Programmable Controller Interface (PCI) A type of network communications protocol used in Chrysler brand vehicles.

PROM Programmable read-only memory.

Propagation Sound is the movement of air that the ear interprets as sound. Sound travels through the air, which is called propagation.

Propane Propane is the most widely used of all of the alternative fuels. Propane is normally a gas but is easily compressed into a liquid and stored in inexpensive containers. When sold as a fuel, it is also known as liquefied petroleum gas (LPG) or LP-gas because the propane is often mixed with about 10% of other gases, such as butane, propylene, butylene, and mercaptan to give the colorless and odorless propane a smell.

Propeller shaft A term used by many manufacturers for a drive shaft.

Proportioning Valve A proportioning valve improves brake balance during hard stops by limiting hydraulic pressure to the rear brakes.

Protection A circuit breaker or fuse used to open the circuit if excessive current flows though the circuit.

Proton exchange membrane (PEM) The Proton Exchange Membrane fuel cell is also known as a Polymer Electrolyte Fuel Cell (PEFC). The PEM fuel cell is known for its lightweight and compact design, as well as its ability to operate at ambient temperatures.

PTC circuit protection Positive temperature coefficient (PTC) circuit protectors are solid-state (without moving parts). Like all other circuit-protection devices, PTCs are installed in series in the circuit being protected.

P-type material Silicon or germanium doped with boron or indium.

Public Charging Stations (PCS) Public Charging Stations (PCS) are available at many locations and most commercial level 2 charging stations.

Pull chain A type of chain used in a CVT transmission/transaxle that is made up of links and link pins, much like a silent chain. The ends of the link pins contact the pulley sides. This style is also called a luk chain drive.

Pull Vehicle tends to go left or right while traveling on a straight, level road.

Pull-in winding One of two electromagnetic windings inside a solenoid used to move a movable core.

Pulse train A DC voltage that turns on and off in a series of pulses.

Pulse width The amount of “on” time of an electronic fuel injector.

Pulse wipers Windshield wipers that operate intermittingly. Also called delay wipers.

Pulse-width modulation The amount of time the current is on compared to the amount of time it is off is called pulse width, and the control of a solenoid using this pulsing-on-and-off method is called pulse-width modulation.

Pump cell A pump cell is the area above the Nernst cell which is another zirconia layer with two electrodes. The two cells share a common ground, which is called the reference.

Pump-up The job of the hydraulic lifter is to take up all clearance in the valve train. Occasionally, engines are run at excessive speeds. This tends to throw the valve open, causing valve float. During valve float, clearance exists in the valve train. The hydraulic lifter takes up this clearance as it is designed to do. When this occurs, it keeps the valve from closing on the seat, a process called pump-up. Pump-up does not occur when the engine is operated in the speed range for which it is designed.

Punch A hand tool designed to be used with a hammer to drive out pins.

Pup (mini) converter Some vehicles have used a small, quick heating oxidation converter, called a preconverter or a pup (mini) converter, that connects directly to the exhaust manifold outlet.

Purchase Order (PO) A purchase order (PO) is used to enable a store or business to purchase parts. It describes the component and the quantity being purchased along with billing information.

Purge valve The canister purge valve, also called the canister purge (CANP) solenoid, is normally closed and is pulsed open by the PCM during purging. The purge valve is connected to intake manifold vacuum using a rubber hose to draw gasoline vapors from the charcoal canister into the engine when the purge valve is commanded open.

Push belt A type of belt used in a CVT transmission/transaxle that is made of about 400 wedge-shaped segments that are held together by two steel bands. Each band is made from multiple layers to allow flexibility. The segment sides contact the pulley sides. A push-belt is often called the Van Doorne design.

Pushrod engine An overhead valve engine (OHV engine) is a pushrod engine and is also known as a reciprocating piston engine.

Putty knife The scraper most frequently used is a putty knife, or a plastic card. The broad blade of the putty knife helps avoid scratching the surface as it is used to clean the parts.

PWM Pulse-width modulation. The control of a device by varying the on-time of the current flowing through the device.

Pyrolytic A pyrolytic (high-temperature) oven cleans engine parts by decomposing dirt, grease, and gaskets with heat in a manner similar to that of a self-cleaning oven.

Quench area The squish area can also be the quench area where the air-fuel mixture is cooled by the cylinder head. The quench area is the flat area of the combustion chamber that is above the flat area of the piston. As the piston moves upward on the compression stroke, the air-fuel mixture is forced from this area as the piston gets near the top.

Quill The transmission front bearing retainer has a long, hollow tube extending toward the engine. The release bearing sleeve slides on the outer surface of this tube, which is commonly called the quill, quill shaft, or candlestick

Ra Roughness average; a measurement of surface finish. The lower the number, the smoother the surface.

Rack support A spring-loaded unit that is used to hold the rack part of a rack and pinion steering gear assembly in proper position.

Rack-and-pinion electric power steering (R-EPS) The rack-mounted system has the assist motor attached to the rack and is often called a rack-and pinion electric power steering (R-EPS) system.

Rack-and-pinion The term rack and pinion is a description of the basic design of this type of steering gear. The rack-and-pinion steering gear is widely used because it is light in weight and takes less space than a conventional steering gear. The input gear of a rack-and-pinion steering gear is a pinion gear that receives rotary input from the steering shaft. the rack is a rod with gear teeth machined into one side. The pinion gear teeth mesh with the teeth on the rack so that when the pinion gear turns, it pushes the rack from side to side.

Radial force variation (RFV) The out-of-round runout of a wheel or tire which can cause a tramp-type (up and down) vibration if excessive.

Radial load The load applied to a bearing 90 degrees from the axis. The weight of the vehicle applies a radial load to the wheel bearing.

Radial runout A measure of the amount a tire or wheel is out of round. Excessive radial runout can cause a tramp-type vibration.

Radiation Radiation is a method of energy transfer where heat is transmitted through the air.

Radiator A cooling system component used to dissipate heat from the coolant to the surrounding air.

Radio choke A small coil of wire installed in the power lead, leading to a pulsing unit such as an IVR to prevent radio interference.

Radio frequency (RF) Frequency, also known as radio frequency (RF), is the number of times a particular waveform repeats itself in a given amount of time and is measured in hertz (Hz).

Radio frequency identification (RFID) Most security systems today use a Radio Frequency Identification (RFID) security system which has two main component which is a key fob and/or a transponder key.

Radius rod A suspension component to control longitudinal (front-to-back) support and is usually attached with rubber bushings to the frame at one end and the axle or control arm at the other end. Also see strut rod.

Rain-sense wipers Windshield wiper that use an electronic sensor to detect the presence of rain on the windshield and start operating automatically if the wiper switch is in the Auto position.

RAM Random access memory.

Ramp Valve trains using solid lifters must run with some clearance to ensure positive valve closure, regardless of the engine temperature. This clearance is matched by a gradual rise in the cam contour, called a ramp

Range anxiety Range anxiety is a feeling many drivers' experience when driving an electric vehicle because they fear running out of electric battery energy before they reach their destination.

Range per hour (RPH) Level 2 charging adds about 25 miles of Range Per Hour (RPH), labeled as miles per hour (MPH) on the dash display of a Nissan Leaf.

Range shift Range shift allows low range to be selected to deliver high torque at low speeds to the drive wheels. Low range usually provides a 2:1 to 3:1 gear reduction. High range (usually 1:1) simply transfers engine torque at the same speed as the output shaft of the transmission.

Ratchet A handle used to rotate a socket, which is reversible and allows the socket to be rotated in one direction and then free movement in the opposite direction of rotation.

Ratio control motor A stepper motor that changes the position of the upper end of the pulley ratio link in a CVT transmission/transaxle. The stepper motor controls the hydraulic ratio valve through the link, which in turn, controls fluid flow to the piston.

Rationality Rationality checks refer to a PCM comparison of input values to values from other sensors to determine if they make sense and are normal (rational).

Ravigneaux gear set The Ravigneaux system has the following: 1. Two sun gears. 2. Two planet pinion sets, one longer than the other, supported in one carrier. 3. A single ring gear

RBS (rubber-bonded socket) Because there is no sliding friction inside the tie rod end, no lubrication was needed. This type of tie rod end is called RBS (rubber-bonded socket).

RCRA Resource Conservation and Recovery Act.

Reaction member The drive member of a planetary gear set is called the input member, the held member, the reaction member, and the driven member, the output member.

Reaction pads All braking force is transferred through the caliper to the mount. The places where the caliper contacts the caliper mount are called the abutments, reaction pads, or ways.

Real-time dampening (RTD) A brand name for a General Motor vehicle electronic suspension system.

Rear cross-traffic warning (RCTW) A rear cross-traffic warning system sounds an audible warning when a vehicle is crossing at the rear while backing. Some vehicles are capable of automatically braking to avoid a collision.

Rear end A differential is also called a rear end or abbreviated simply as a diff. Whenever any vehicle makes a turn, the outside wheel must travel a greater distance than the inside wheel.

Rear steer A construction design of a vehicle that places the steering gear and steering linkage behind the centerline of the front wheels.

Rebound clips Clips used around the leaves of a leaf spring.

Rebuilding A complete engine reconditioning job is called rebuilding. Sometimes, this type of reconditioning is called a major overhaul.

Rebuilt A remanufactured component (also called rebuilt) has been used on a vehicle until the component wore out or failed. A remanufacturer totally disassembles the component, cleans, machines, and performs all the necessary steps to restore the part to a "like new" look and function.

Recall A notification to the owner of a vehicle that a safety issue needs to be corrected.

Recirculation Inside air usually called recirculation.

Reclaimed refrigerant Reclaimed refrigerant is refrigerant that has been sent out to an EPA-certified reclamation facility where it has been processed and certified as if it were new refrigerant.

Recombinant battery A battery design that does not release gasses during normal operation. AGM batteries are known as recombinant batteries.

Recovery The act of removing refrigerant from a system so that it can be recycled for reuse.

recovery, recycling, and recharging (RRR) Most refrigerant recovery units are made as part of the recovery, recycling, and recharging (RRR) machine and contain two service hoses (a low and high side) that are connected to the system service ports.

Rectifier bridge A group of six diodes, three positive (+) and three negative (-) commonly used in alternators.

Recycled refrigerant Recycled refrigerant is refrigerant that that has been processed at a service facility (shop or dealership) by using recycling equipment that is SAE certified.

Recycling The act of using portable equipment to clean debris, oil, water, and noncondensable gases from refrigerant so it can be reused in a system.

Red brake warning lamp (RBWL) The red brake warning lamp (RBWL) lights whenever a hydraulic system failure occurs or low brake fluid level has been detected. The red brake warning lamp lights when the ignition is turned on as a bulb check, then goes out, unless a hydraulic fault has been detected.

Red brake warning lamp The dash-mounted warning lamp that lights if a hydraulic system fault is detected.

Reed valve The typical valve used in compressors is the reed valve: a one-way, flap-type check valve that is built into the valve plate that seals one or more cylinders.

Reference electrode Ambient-side electrode is exposed to outside (ambient) air and is the signal electrode, also called the reference electrode.

Reference Material Reference Materials provide information to the parts specialist and include new item bulletins, product information bulletins, catalog errors, and parts specifications.

Reference A reference is someone who is willing to tell a possible employer about you, including your skills and talents, as well as your truthfulness and work habits.

Refractometer A device used to measure battery state of charge by allowing light to pass through an electrolyte sample.

Regeneration A process of taking the kinetic energy of a moving vehicle and converting it to electrical energy and storing it in a battery.

Reid vapor pressure (RVP) A method of determining vapor pressure of gasoline and other petroleum products. Widely used in the petroleum industry as an indicator of the volatility of gasoline.

Relative compression test Relative compression test uses the starter motor current to determine the compression values of all cylinders. the advantage of a relative compression test is that no pressure sensors are needed to check each individual cylinder and all cylinders can be tested at the same time.

Relative humidity (RH) sensor A few vehicles use a relative humidity (RH) sensor to determine the level of in-vehicle humidity. High RH increases the cooling load. A relative humidity sensor uses the capacitance change of a polymer thin film capacitor to detect the relative amount of moisture in the air.

Relative humidity Relative humidity is the percentage of how much moisture is present in the air compared to how much moisture the air is capable of holding at that temperature.

Relay An electromagnetic switch that uses a movable arm.

Release bearing A clutch assembly consists of a clutch disc that is splined to the input shaft of the transmission/transaxle. When the driver depresses the clutch pedal, a throw-out bearing (release bearing) is forced against the fingers of the pressure plate.

Reluctance The resistance to the movement of magnetic lines of force.

Remote keyless entry (RKE) While the remote keyless entry (RKE) part of the key fob has a battery to power the transmitter, the RFID chip part of the key fob does not require a battery to function.

Remote reservoir A type of power steering pump where the fluid is in a reservoir separate from the pump.

Remote start A remote start is the ability to start the engine of the vehicle from a distance by using a remote control.

Remove and inspect (R & I) R & I is often used to indicate remove and inspect to check a component for damage.

Remove and replace (R & R) Parts replacement is often called R & R, meaning remove and replace.

Removers This term is used to describe hand tools, which are designed to remove broken studs, bolts, and other fasteners.

Renewal parts Parts manufactured to be sold for use after the vehicle is made are often referred to as aftermarket parts or renewal parts.

Repair order (RO) A work order, also called a repair order or RO contains all vehicle and customer information plus what service work is requested by the customer.

Repair order log A repair order log (or daily work control log) is used to track the repair and completion process or the lead time for each repair order. It provides an overview of all the vehicles that are in the shop on a given day.

Replenishing port The Society of Automotive Engineers (SAE) term for the rearward low-pressure master cylinder port. Also called inlet port, bypass port, filler port or breather port.

Reserve capacity The number of minutes a battery can produce 25 A and still maintain a battery voltage of 1.75 V per cell (10.5 V for a 12 V battery).

Residual magnetism Magnetism remaining after the magnetizing force is removed.

Residual or rest pressure Residual or rest pressure prevents vapor lock and hot-start problems on these systems.

Resistance The opposition to current flow measured in ohms.

Resonate When back-and-forth deflections occur at the same vibration frequency (number of vibrations per second) as that of another engine part, the parts will vibrate together. When this happens, the parts are said to resonate.

Resonator The resonator is similar to a muffler and is usually connected in the exhaust stream before the muffler. The resonator helps to quiet the sound of combustion before the exhaust gases reach the muffler.

Restricted exhaust In a vacuum a needle that drops to near zero when the engine is accelerated rapidly and then rises slightly to a reading below normal indicates an exhaust restriction.

Resume A statement of your background and experience submitted to a potential employer.

Retainer plate-type axle Rear axle bearings are either sealed or lubricated by the rear-end lubricant. The rear axle must be removed from the vehicle to replace the rear axle bearing. There are two basic types of axle retaining methods named retainer plate-type or C-lock.

Retainer The valve keepers (also called locks) secure the spring retainer to the stem of the valve.

Return path (ground) A return path (ground) for the electrical current from the load back to the power source so that there is a complete circuit.

Return policies Return policies vary by store. For example, for some companies, electrical and electronic parts are sometimes not returnable for reimbursement.

Returnability The ability of the steering wheel to return to the straight ahead position after making a turn.

Reverse bias Current flow in the opposite direction from normal.

Reverse cooling The coolant flows from the radiator to the cylinder head(s) before flowing to the engine block.

Reverse twist ring A reverse twist ring is produced by chamfering the ring's lower inner corner. This seals the lower outer section of the ring and piston ring groove, thus improving oil control.

Reverse There are two common reverse gear designs used on transmissions a Sliding gear and Constant-mesh gear.

Rheostat A two-terminal variable resistor.

Rhodium The converter substrate contains small amounts of rhodium, palladium, and platinum. These elements act as catalysts. As mentioned, a catalyst is an element that starts a chemical reaction without becoming a part of, or being consumed in, the process.

Rich indicator If CO is high, the exhaust is rich, so CO is called the "rich indicator"

Ride height The height of the vehicle. Also called the trim height.

Right-to-know laws Laws that state that employees have a right to know when the materials they use at work are hazardous.

Rim width The width of a wheel measured between bead sections.

Ring (annulus) gear The outermost member of the gear set is the ring gear, the internal type with teeth inside. the ring gear is sometimes called an annulus or internal gear. the pinion gears are in simultaneous mesh with both the sun gear and the ring gear.

Ring gap The piston ring gap allows some leakage past the top compression ring. This leakage is useful in providing pressure on the second ring to develop a dynamic sealing force. The amount of piston ring gap is critical.

Ring gear runout Use a dial indicator to check ring gear runout If any of the visual measurement tests indicate a problem or a noise analysis indicates a bearing problem, the axle assembly should be disassembled for further analysis and service.

Ring gear The large gear inside a differential assembly, which meshes with the drive pinion gear.

Riveted linings Brake lining that is held to the brake shoe using rivets.

Road crown A roadway where the center is higher than the outside edges. Road crown is designed into many roads to drain water off the road surface.

Role model A role played by a mentor.

Roller bearings Antifriction bearings that use hardened steel rollers between the inner and outer races.

Roller cell In the roller cell or vane pump, the impeller draws fuel into the pump, and then pushes it out through the fuel line to the injection system.

Roller chain type A roller chain is a type of camshaft chain that is noisy, but operates with less friction and stretches less than the silent type of chain.

Rolling circumference The distance a tire travels when rotated one revolution.

ROM Read-only memory.

Root cause The root cause is the true cause of a failure, which may not be noticed at first.

Root The tooth root is the depression lying between two teeth, and the crown is the very top of each tooth.

Root-mean-square (RMS) A method of displaying variable voltage signals on a digital meter.

Roots supercharger The roots supercharger was patented in 1860 as a type of water pump to be used in mines. Later, it was used to move air and is used today on two-stroke-cycle Detroit diesel engines and other supercharged engines. The roots-type supercharger is called a positive displacement design, because all of the air that enters is forced through the unit.

Rosin-core solder A type of solder for use in electrical repairs. Inside the center of the solder is a rosin that acts as a flux to clean and help the solder flow.

Rotary control valve A power steering valve that operates by rotating an inner valve inside an outer valve to control the amount of steering assist.

Rotary engine A rotary engine has a rotating combustion chamber and has a triangular-shaped rotor turning in a housing. The housing is in the shape of a geometric figure called a two lobed epitrochoid. A seal on each corner, or apex, of the rotor is in constant contact with the housing, so the rotor must turn with an eccentric motion.

Rotary flow Rotary flow is created by the rotation of the torque converter and causes the oil (ATF) to flow around the circumference of the torque converter.

Rotary vane pump The pump consists of a central impeller disk, several rollers or vanes that ride in notches in the impeller, and a pump housing that is offset from the impeller centerline.

Rotor The rotating part of a generator where the magnetic field is created.

RPO (regular production option) The RPO (regular production option) code will tell the technician the type of suspension used.

RTV Room-temperature vulcanization.

Rubber band effect A condition that affect some CVT units where the vehicle speed slowly catches up to the engine speed, and is most noticeable only during periods of rapid acceleration.

Rubber-coated metal (RCM) gaskets A type of gasket.

Run-flat tires Tires specially designed to operate for reasonable distances and speeds without air inside to support the weight of the vehicle. Run-flat tires usually require the use of special rims designed to prevent the flat tire from coming off the wheel.

Running compression test A running compression test, also called a dynamic compression test, is done with the engine running rather than during engine cranking as is done in a regular compression test.

RVP Reid vapor pressure. A measure of the volatility at exactly 100 degrees F.

RVS Remote Vehicle Start. A general Motor's term for the system that allows the driver to start the engine using a remote control.

Rzeppa joint The Rzeppa joint transfers torque through six round balls that are held in position midway between the two shafts.

R-744 Refrigerant that is carbon dioxide (CO2)

Saddles The first step in determining the condition of the main bearing bores is to determine if the bore alignment in the block is straight. These bores are called the saddles.

SAE J2534 version 5.0 The SAE J2534 version 5.00 is the newest standard and includes all the changes required in the previous updates and serves to improve the communication through the J1962 connector.

SAE J2534 SAE J2534 is a standard for communications between a computer and a vehicle. The original standard was introduced in February of 2002, and was identified as version 02.02.

SAE J2534-1 The SAE J2534 standard was updated in December of 2004. The new standard was identified as version 04.04 or more commonly as SAE J2534-1. The changes in the second version of the standard supported specific requirements of Ford and Chrysler that were not addressed in the first standard that related to J1850 class 2 communication protocols.

SAE J2534-2 An updated SAE J2534 standard referred to as SAE J2534-2. The updates addressed issues related to single wire CAN Bus communication and issues related to the GM UART communication protocol.

SAE Society of Automotive Engineers.

Safety stands A metal device with an adjustable vertical support that is designed to support a vehicle after it has been raised off the ground. Also called a *jack stand*.

Safety switch A switch on the clutch pedal that prevents starter operation unless the clutch pedal is depressed.

SAI Steering axis inclination (SAI) is the inward tilt of the steering axis.

Sales Objections Sales Objections are when a customer has a problem with the price or item.

Same-phase steering A type of four-wheel steering system where the front and rear wheels are steered in the same direction. Same-phase steering improves steering response, especially during rapid-lane-change-type maneuvers.

SAPS ACEA oil also requires low levels of sulfated ash, phosphorous, and sulfur, abbreviated SAPS, and has a high-temperature/ high-shear rate viscosity, abbreviated HTHS

SAR Supplemental Air Restraints. Another term used to describe an airbag system.

Saturation The point of maximum magnetic field strength of a coil.

Scan tool Electronic hand-held testers, called scan tools, are needed to access (retrieve) stored diagnostic trouble codes (DTCs) and view sensor and system data.

Schmitt trigger A Schmitt trigger inside the sensor itself converts an analog signal into a digital signal.

Schrader valve A type of valve used in tires, air-conditioning, and fuel injection systems. Invented in 1844 by August Schrader.

Scientific method The scientific method is a series of steps taken to solve a problem. These steps help eliminate errors and to achieve an accurate result.

Scientific notation Scientific notation is written as a number multiplied by the number of zeros to the right or left of the decimal point

Score resistance Bearings have a characteristic called score resistance. It prevents the bearing materials from seizing to the shaft during oil film breakdown.

Scoring Grooves worn into the drum or disc braking surface.

SCR Silicon Controller Rectifier

Scraper ring A scraper ring does a good job of oil control and is usually recommended for use at the second compression ring.

Scratch cut Turn the drum by hand before turning on the lathe to be sure everything is clean. Advance the tool bit manually until it just contacts the drum. This is called a scratch cut.

Screwdriver A hand tool designed to remove or insert screws.

Scroll compressor A compressor design that uses two meshed scrolls to pump refrigerant.

Scroll A smoothly curved passage that changes the fluid flow direction with minimum loss in velocity.

Scrub radius Refers to where an imaginary line drawn through the steering axis intersects the ground compared to the centerline of the tire. *Zero* scrub radius means the line intersects at the center line of the tire. *Positive* scrub radius means that the line intersects below the road surface. *Negative* scrub radius means the line intersects above the road surface. It is also called *steering offset* by some vehicle manufacturers.

SDARS Satellite Digital Audio Radio Services. Another term used to describe satellite radio.

SDS All hazardous materials must be properly labeled, and information about each hazardous material must be posted on safety data sheets (SDS), formally called material safety data sheets (MSDS) available from the manufacturer.

Seal cartridge A compressor shaft seal that keeps refrigerant from leaking.

Seal driver A hand tool used with a mallet or hammer to seat seals into a seal groove.

Seal puller A hand tool designed to remove seals.

Seal seat A gasket or rubber O-ring is used so that the seal seat makes a gas-tight seal at the housing, and the seat has an extremely smooth sealing face.

Sealed lead–acid (SLA) A type of battery usually an absorbed glass mat (AGM) design that is not vented to thee outside and therefore can used in the interior or a vehicle.

Seasonal Item A seasonal item is something that may not normally be stocked during certain times of the year. Some seasonal items are stocked throughout the entire year but not in large quantities.

Second gear In second gear, the shift linkage slides the 1–2 synchronizer sleeve forward, away from the first speed gear and toward the second speed gear. The synchronizer assembly releases first gear, then locks the second speed gear to the output shaft.

Secondary air injection (SAI) The secondary air-injection (SAI) system provides the air necessary for the oxidizing process either at the exhaust manifold or inside the catalytic converter.

Secondary ignition circuit The components necessary to create and distribute the high voltage produced in the secondary windings of the coil are called the secondary ignition circuit.

Secondary oil pressure (SOP) The fluid pressure applied to the secondary pulley of a CVT transmission/transaxle. The pressure measured is called the secondary oil pressure (SOP).

Secondary pressure sensor (SPS) A pressure transducer used to monitor secondary pulley pressure. The pressure measured is called the secondary oil pressure (SOP).

Secondary shoe The brake shoe installed facing the rear of the vehicle.

Secondary vibration Four-cylinder engines, however, suffer from a vibration at twice engine speed. This is called a secondary vibration, which is a weak high-frequency vibration caused by a slight difference in the inertia of the pistons at top dead center, compared to bottom dead center.

Second-class lever A second-class lever increases the force applied to it and passes it along in the same direction.

Section 609 (clean air act) The Clean Air Act of 1990 specified that the production of R-12 refrigerant ceased at the end of 1995. Section 609 of the Clean Air Act required the following: 1. All technicians who service or repair automotive air-conditioning systems shall be properly trained and certified. 2. Recovery and recycling equipment must be properly approved. 3.Each shop that performs automotive air-conditioning service should comply to the Environmental Protection Agency (EPA).

Sector gear A section of a gear inside a steering gear that is attached to the sector shaft. Also called the pitman shaft.

Sector shaft The output shaft of a conventional steering gear. It is a part of the sector shaft in a section of a gear that meshes with the worm gear and is rotated by the driver when the steering wheel is turned. It is also called a *pitman shaft.*

Sediment chamber A space below the cell plates of some batteries to permit the accumulation of sediment deposits flaking from the battery plates. A sediment chamber keeps the sediment from shorting the battery plates.

Select low principle Some four-wheel ABS have a separate wheel speed sensor for each front wheel but use a common speed sensor for both rear wheels. These are called "three-channel" systems. The rear wheel speed sensor is mounted in either the differential or the transmission. The sensor reads the combined or average speed of both rear wheels. This type of setup saves the cost for an additional sensor and reduces the complexity of the system by allowing both rear wheels to be controlled at the same time which is called the select low principle.

Selectable ride (SR) A brand name for a General Motor vehicle electronic suspension system.

Selective catalytic reduction (SCR) A type of exhaust emission system that uses urea injection to reduce oxides of nitrogen emissions from diesel engines.

Self-aligning spacer (SAS) A double cone used to spread the force of the retaining nut on the spindle of a brake lathe.

Self-energizing action A brake shoe, that when applied, develops a wedging action that assists the braking force applied by the wheel cylinder.

Self-induction The generation of an electric current in the wires of a coil created when the current if first connected or disconnected.

Self-parking Several vehicle manufacturers offer a self-parking feature that uses the electric power steering to steer the vehicle. The driver has control of the brakes.

Self-propelled vehicle Self-propelled vehicles are vehicles that moved under their own power.

Self-tapping screw A screw that has a tapered tip which allows the screw to form threads in the metal.

Semiconductor A material that is neither a conductor nor an insulator; has exactly four electrons in the atom's outer shell.

Semi-independent suspension A type of rear suspension that allows some transfer of motion to the opposite side.

Semimetallic The term semimetallic refers to brake lining material that uses metal, rather than asbestos, in its formulation. It still uses resins and binders and is, therefore, not 100% metal, but rather semimetallic. Semimetallic pads are commonly called "semi-mets."

Semi-trailing arm A type of rear suspension that controls both side-to-side and front-to-rear motion.

Separator plate The separator plate, also called a spacer plate, provides rigidity and contains calibrated holes and openings that help manage fluid flow.

Sequential fuel injection (SFI) A fuel injection system in which injectors are pulsed individually in sequence with the firing order.

Sequestration The process of storing carbon dioxide under-ground is called sequestration.

Serial communications interface (SCI) A type of serial data transmission used by Chrysler.

Serial data Data that is transmitted by a series of rapidly changing voltage signals.

Series circuit An electrical circuit that provides only one path for current to flow.

Series flow system In the series flow system, the coolant flows around all the cylinders on each bank. The coolant then enters the rear of the heads. In the heads, the coolant flows forward to a crossover passage on the intake manifold outlet at the highest point in the engine cooling passage. This is usually located at the front of the engine. The outlet is either on the heads or in the intake manifold.

Series-parallel circuits Any type of circuit containing resistances in both series and parallel in one circuit.

Series-parallel flow system Some engines use a combination of the series and parallel flow system.

Serpentine (Poly V) A serpentine (or Poly V) is a single continuous belt used to drive multiple peripheral devices in an automotive engine, such as an alternator, power steering pump, and/or water pump. Serpentine (or Poly V) belts are to be replaced every four to seven years.

Service advisor A person who talks to the customer about a vehicle service and completes the work order.

Service bay A work area for a vehicle, with or without a lift. Also called a *stall*.

Service brakes The main driver-operated vehicle brakes.

Service consultant A service advisor, also called a service writer or service consultant, is the person at the dealership or shop designated to communicate the needs of the customer and accurately complete a work order.

Service History Documentation of a vehicle's past service, maintenance, and repairs.

Service information Includes service manuals, owner's manuals, CD ROM discs, Internet sites, or other sources where vehicle information is found.

Service manager The person in charge of a shop or dealer service department.

Service Pricing Menu A Service Pricing Menu provides a quick reference for the service consultant to identify and accurately quote the cost for the most common repairs that the shop performs.

Service writer A service advisor, also called a service writer or service consultant, is the person at the dealership or shop designated to communicate the needs of the customer and accurately complete a work order.

Servo A band is applied by using a hydraulically operated piston that travels inside a machined cylinder bore. This piston and cylinder assembly is known as a servo.

Servomotor The actuator in an electronic throttle control (ETC) system.

Setback The amount the front wheels are set back from true parallel with the rear wheels. Positive setback means the right front wheel is set back farther than the left. Setback can be measured as an angle formed by a line perpendicular (90°) to the front axles.

Shackles one end of the leaf spring is attached to the frame with movable mounting hangers called shackles.

Shift cooling multiplex solenoid (SHCMS) Controls position of gearshift forks as well as cooling of clutch in a dual clutch automatic transmission/transaxle.

Shimmy A vibration that results in a rapid back and forth motion of the steering wheel. A bent wheel or a wheel assembly that is not correctly dynamically balanced are common causes of shimmy.

Shock absorbers A suspension component that links and controls the action and reaction of the springs.

Shoe anchors A round part at the top of most backing plates used to prevent the brake shoes from rotating with the drum during a brake application.

Shoe contact areas Raised areas on the backing plate of a drum brake where the brake shoes contact.

Shoe rim Another name for the lining table where the brake lining is attached to the brake shoe.

Shoe support pads Six areas on the backing plate of a drum brake where the lining makes contact.

Shoe web The support under the shoe table on a drum brake shoe.

Shop Foreman A journeyman service technician who helps solve technical problems and helps service technicians.

Shop supervisor A person at a shop that supervises the service technicians and often diagnoses vehicle problems Signal electrode - This electrode is exposed to outside (ambient) air and is the signal electrode, also called the reference electrode or ambient air electrode.

Short block The quickest way to get a vehicle back in service is to exchange the faulty engine for a different one. In an older vehicle, the engine may be replaced with a used engine from a salvage yard. In some cases, only a reconditioned block, including the crankshaft, rods, and pistons, is used. This replacement assembly is called a short block.

Short circuit A circuit in which current flows, but bypasses some or all the resistance in the circuit. A connection that results in a "copper-to-copper" connection.

Short/long arm (SLA) The two main links in a short/long-arm (SLA) suspension are the upper control arm and the lower control arm. The upper control arm is shorter than the lower one.

Shorted a condition of being shorted such as a short circuit.

Short-to-ground A short circuit in which the current bypasses some or all the resistance of the circuit and flows to ground. Because ground is usually steel in automotive electricity, a short-to-ground (grounded) is a "copper-to-steel" connection.

Short-to-voltage A circuit in which current flows, but bypasses some or all the resistance in the circuit. A connection that results in a "copper-to-copper" connection.

Shunt A device used to divert or bypass part of the current from the main circuit.

Siamese port On some older engines, two cylinders share the same port because of the restricted space available. Shared ports are called Siamese ports.

Side clearance The space in the ring groove above the ring is called the side clearance

Side gears The gears inside a differential that attach to the axles.

Side-channel pump A turbine pump is the most common because it tends to be less noisy. Sometimes called turbine, peripheral, and side-channel, these units use an impeller that accelerates the fuel particles before actually discharging them into a tract where they generate pressure via pulse exchange.

Sidewall The side of a tire.

Sight glass A window in the liquid line or receiver–drier that allows observation of refrigerant flow used in older R-12 systems.

Signal electrode This electrode is exposed to outside (ambient) air and is the signal electrode, also called the reference electrode or ambient air electrode.

Significant new alternatives policy (SNAP) An EPA process for determining acceptable replacement refrigerants for R-12.

Silent chain type The silent chain type (also known as a flat-link type, or Morse type for its original manufacturer) operates quietly but tends to stretch with use. The metal links themselves do not "stretch" but, instead, the pin bushings at each joint wear, which causes the chain to become longer.

Silicon A semiconductor material.

Silicone brake fluid A type of brake fluid that is purple and does not absorb moisture.

Silicone coupling A type of thermostatic fan that is mounted between the drive pulley and the fan.

Silicone grease Lubrication of moving or sliding components prevents noise from being generated as the parts move over each other. Many vehicle manufacturers recommend Silicone grease.

Simpson gear set the Simpson gear set consists of two simple planetary gear sets that share a common sun gear. This combination is capable of providing three forward gears, as well as neutral and reverse.

Sine with dwell (SWD) test The standardized test used to determine if an electronic stability control system functions okay is called the sine with dwell (SWD) test.

Single cell A type of wide-band oxygen sensor that uses one cell using four wires; two for the heater and two cell wires.

Single overhead camshaft (SOHC) Newer engine designs feature overhead camshafts (OHC), called single overhead camshaft (SOHC) designs and engines that use two overhead camshafts per bank of cylinders called double overhead camshaft (DOHC) designs.

Single stroke bleeding method A method of manual brake bleeding where the brake pedal is depressed one time, held until the bleeder is closed and the released.

Single-cut file A file that has just one row of cutting teeth.

SIR Supplemental Inflatable restraints. Another term for air bags.

Skewed A skewed thermostat works, but not within the correct temperature range. Therefore, the engine could overheat or operate cooler than normal, or even do both.

Skirt Piston ring grooves are located between the piston head and skirt. The width of the grooves, the width of the lands between the ring grooves, and the number of rings are major factors in determining minimum piston height. The outside diameter of the lands is about 0.02 to 0.04 inch (0.5 to 1 mm) smaller than the skirt diameter.

SLA Abbreviation for short/long arm suspension.

Sleep mode Is when the vehicle is stopped, the sensor "goes to sleep" to help improve battery life. In this mode, the transmitter still will broadcast tire inflation information every hour or every six hours, depending on the sensor.

Sleeve bearing Most engine bearings are one of two types which are plain bearing and sleeve bearing.

Sleeve The bore of the barrel (sleeve) is threaded and a spindle screws into the bore. The thimble rotates over the sleeve on a screw that has 40 threads per inch.

SLI SLI means starting, lighting, and ignition, and describes the use of a typical automotive battery.

Sliding caliper A type of disc brake caliper that is free to move within a limited range.

Sliding reverse gear With a sliding reverse gear design, such as on the Borg Warner T5, the shift linkage slides the reverse idler gear on its shaft until it engages the reverse gears on the countershaft and output shaft gear. Both gears are fixed to their respective shafts.

Sliding sleeve In synchronized construction there are a number of design variations, all are similar and include a hub, a sliding sleeve, a blocker ring, (or stop ring or synchronizer ring), keys, and springs.

Slip joint hand tool which has two positions allowing the use of two different ranges of sizes.

Slip-joint pliers A hand tool which has two positions allowing the use of two different ranges of sizes.

Slipper skirt A slipper skirt design piston is shorter on the two sides that are not thrust surfaces.

Slip-ring-end (SRE) housing The rear housing, or the slip-ring-end (SRE) housing, usually contains either a roller bearing or ball bearing support for the rotor and mounting for the brushes, diodes, and internal voltage regulator (if so equipped).

Slope The ratio of front to rear brake pressure by a proportioning valve.

Slugging Charging liquid into a compressor which can cause severe damage.

Small-hole gauge A handheld measuring tool that is adjustable to fit inside small holes. A micrometer is then used to measure the gauge to determine the inside diameter of the hole. Also called a *split-ball gauge*.

Smart control head HVAC control heads that have the ability to process data.

Smart motor HVAC door motors that have the ability to process data.

Smog pump The SAI pump, also called an AIR pump, a smog pump, or thermactor pump, is mounted at the front of the engine and can be driven by a belt from the crankshaft pulley. It pulls fresh air in through an external filter and pumps the air under slight pressure to each exhaust port through connecting hoses or a manifold.

Smog The term used to describe a combination of *smoke* and *fog.* Formed by NOx and HC with sunlight.

Smoke machine Vacuum (air) leaks can cause a variety of driveability problems and are often difficult to locate. one good method is to use a machine that generates a stream of smoke. Connecting the outlet of the smoke machine to the hose that was removed from the vacuum brake booster allows smoke to enter the intake manifold. Any vacuum leaks will be spotted by observing smoke coming out of the leak.

Snap ring A spring steel clip that is used to retain an object in a bore by being inserted into a groove.

Snap-ring pliers A hand tool, which is designed to install or remove snap rings.

Society of Automotive Engineers (SAE) A professional organization made up of automotive engineers and designers that establishes standards and conducts testing for many automotive-related functions.

Socket adapter An adapter that allows the use of one size of driver (ratchet or breaker bar) to rotate another drive size of socket.

Socket A tool that fits over the head of a bolt or nut and is rotated by a ratchet or breaker bar.

Soft core plugs Core holes left in the external block wall are machined and sealed with soft core plugs or expansion plugs (also called freeze plugs or Welsh plugs).

Soft skill In any career, including being a service technician, requires people, communication, and teamwork skills, often called soft skills.

Solenoid controlled damper a shock absorber that is electronically controlled by a solenoid.

Solenoid An electromagnetic device that uses a moveable core which can be connected to linkage to move a valve or other device.

Solid axle A solid supporting axle for both front or both rear wheels. Also referred to as a straight axle or nonindependent axle.

Solid valve lifter Valve train clearance is also called valve lash, which is needed to help compensate for thermal expansion and wear. Valve train clearance must not be excessive, or it causes noise or results in premature failure. One method commonly used to make the necessary valve clearance adjustments involves a solid valve lifter, which can be adjusted mechanically at the rocker arm or by changing shims on certain overhead camshaft engines.

Solvent Usually colorless liquids that are used to remove grease and oil.

Soot Particulate matter emitted by diesel engines.

Space frame A type of vehicle construction that uses the structure of the body to support the engine and drive train, as well as the steering and suspension. The outside body panels are nonstructural.

Spalling A term used to describe a type of mechanical failure caused by metal fatigue. Metal cracks then break out into small chips, slabs or scales of metal. This process of breaking up is called spalling.

Spark ignition direct injection (SIDI) In a gasoline direct injection (GDI) system the fuel is squired directly into the combustion chamber. General Motors refers to this as a spark ignition direct-injection(SIDI) system.

Spark knock Secondary rapid burning of the last 3 to 5% of the air-fuel mixture in the combustion chamber. Causes a second flame front that collides with the first flame front causing a knock noise.

Spark line The spark line is a short horizontal line immediately after the firing line.

Spark tester If the engine is equipped with a separate ignition coil, remove the coil wire from the center of the distributor cap, install a spark tester, and crank the engine. See the Tech Tip "Always Use a Spark Tester." A good coil and ignition system should produce a blue spark at the spark tester.

SPDT Single pole, double throw. A type of electrical switch.

Speakers A device consisting of a magnet, coil of wire and a cone which reproduces sounds from the electrical signals sent to the speakers from a radio or amplifier.

Special Order A special order is placed whenever a customer purchases a part that is not normally kept in stock.

Specific energy A fuel cell is a hydrogen powered battery. Hydrogen is an excellent fuel because it has a very high specific energy when compared to an equivalent amount of fossil fuel.

Specific gravity The ratio of the weight of a given volume of a liquid divided by the weight of an equal volume of water.

Speed density Engines that do not use an airflow meter or sensor rely on calculating the amount of air entering the engine by using the MAP sensor and engine speed as the major factors. The method of calculating the amount of fuel needed by the engine is called speed density.

Speed nuts Also called Tinnerman nuts. Used to keep the brake drum on at the assembly plant. Can be removed and discarded when servicing drum brakes for the first time.

Speed rating A letter on most tires that indicates the maximum speed at which the tire is designed to perform.

Spider gears Another name for the pinion gear used in a differential.

Spider Center part of a wheel. Also known as the center section.

Spike protection resistor A resistor usually between 300 and 500 ohms that is connected in a circuit in parallel with the load to help reduce a voltage spike caused when a current following through a coil is turned off.

Spindle The part of a micrometer that moves and contacts the object being measured.

Spit hole Some connecting rods have a spit hole that bleeds some of the oil from the connecting rod journal.

Splay angle The angle between the crankpins on the crankshaft throws is called a splay angle

Splice pack A central point where many serial data lines jam together, often abbreviated SP.

Spline bind A condition where the splines on the yoke of a driveshaft bind and then release as a vehicle is first accelerated after a stop.

Spline phaser A type of variable valve timing actuator that uses a piston inside the cam phaser and rides along the helical splines, which compresses a coil spring. This movement causes the cam phaser gear and the camshaft to move in an opposite direction.

Split point The pressure point where reduction of pressure to the rear brake begins in a proportioning valve.

Split-ball gauge A small-hole gauge (also called a split-ball gauge) is used with a micrometer to measure the inside diameter of small holes, such as a valve guide in a cylinder head.

Split-type (half-shell) bearing Overhead camshaft bearings may be one of two sleeve-type bushings, depending on the design of the bearing supports. They are full round bearings or split-type (half-shell) bearings.

Spoke angle The angle of the steering wheel.

Sponge lead Lead with many small holes used to make a surface porous or sponge-like for use in battery negative plates; the chemical symbol for lead is Pb.

Spontaneous combustion A condition that can cause some materials, such as oily rags to catch fire without a source of ignition.

Sprags A one-way sprag clutch that consists of a hub and a drum separated by a number of figure-eight shaped metal pieces called sprags.

Spread The bearing shell has a slightly larger arc than the bearing housing. This difference, called bearing spread, makes the shell 0.005 to 0.02 inch (0.125 to 0.5 mm) wider than the housing bore. Spread holds the bearing shell in the housing while the engine is being assembled.

Spring pocket Also called a spring seat.

Spring rate The spring rate is the amount of weight it takes to compress a spring a certain distance, such as 200 pounds per inch.

Springs Used as a buffer between the suspension and the frame or body and used to absorb wheel movement plus support the weight of the vehicle.

SPST Single pole, single throw. A type of electrical switch.

Spun bearing Bearing shells that do not have enough crush may rotate with the shaft. The result is called a spun bearing.

Spur gear A spur gear consists of a gear blank with straight-cut teeth around its entire circumference. All gear teeth lie parallel to the centerline, or axis, of the gear. The teeth are shaped so they can mesh without slippage with a second spur gear's teeth positioned along a parallel axis.

Squib The heating element of an inflator module which starts the chemical reaction to create the gas which inflates an air bag.

Squish area This is an area of the combustion chamber where the piston nearly contacts the cylinder head. When the piston is moving upward toward the cylinder head, the air fuel mixture is rapidly pushed out of the squish area, causing turbulence. Turbulence helps mix the air and fuel, thereby ensuring a more uniform and complete combustion.

SRS Supplemental Restraint System. Another term for an airbag system.

Stabilitrak The General Motors version of ESC is called the vehicle stability enhancement system (VSES) and includes an additional level of vehicle control to the EBCM. VSES is also known as Stabilitrak.

Stabilizer bar A hardened steel bar connected to the frame and both lower control arms to prevent excessive body roll. Also called an *anti-sway* or *anti-roll bar.*

Stall speed Stall speed is the engine speed when the engine drives the impeller at the maximum speed possible without moving the turbine.

Stall A work order, also called a repair order or RO, is assigned to a technician who is best qualified to perform the work. The technician gets the keys and drives the vehicle to an assigned service bay (also called a stall), performs the proper diagnosis, gets the necessary parts from the parts department, and completes the repair.

Standard Corporate Protocol (SCP) A network communications protocol used by Ford.

Starter drive A term used to describe the starter motor drive pinion gear with overrunning clutch.

Starter solenoid A type of starter motor that uses a solenoid to activate the starter drive.

State of health (SOH) A signal sent by modules to all of the other modules in the network indicating that it is well and able to transmit.

State tax A typical payroll deduction.

State-of-charge (SOC) The state-of-charge (SOC) is the percentage of the available capacity that can be stored in a battery. A battery that has a state of charge of 100% is fully charged.

Static electricity An electrical charge that builds up in insulators and then discharges to conductors.

Static seal A seal used between two surfaces that are not moving.

Stator A name for three interconnected stationary windings inside an alternator. A rotating rotor provides a moving magnetic field and induces a current in the windings of the stator.

Steam slits In series flow systems, bleed holes or steam slits in the gasket, block, and head perform the function of letting out the steam.

Steering angle sensor (SAS) The steering angle sensor (SAS) is usually located at the base of the steering column inside the vehicle and monitors the driver's steering input from straight ahead. It also monitors how fast the driver is turning the wheel and reports this information to body control module (BCM) in most applications.

Steering dampener A steering dampener is used on many pickup trucks, sport-utility vehicles (SUVs), and many luxury vehicles designed with a high-positive-caster setting. The dampener helps prevent steering wheel kickback when the front tires hit a bump or hole in the road and also helps reduce steering wheel shimmy that may result from the high-caster setting.

Steering knuckle The inner portion of the spindle that pivots on the king pin or ball joints.

Steering offset *Scrub radius is also called steering offset by some vehicle manufacturers.*

Steering position sensor (SPS) The PSCM uses the steering position sensor (SPS) to determine the steering system on-center position.

Steering shaft torque sensor The PSCM uses the steering shaft torque sensor as a main input for determining steering direction and the amount of assist needed.

Steering shaft The part of the steering that connects the steering wheel to the steering gear assembly.

Steering stops Steering stops are the projections or built-up areas on the control arms of the front suspension designed to limit the steering movement at full lock.

Steering wheel controls Steering wheel controls are steering wheels that include buttons to allow the driver to control certain audio, vehicle information, and HVAC functions. The purpose of having steering wheel controls is to allow the driver to keep their hands on the wheel and their eyes on the road at all times.

Steering wheel position sensor A sensor that determines in which direction and how fast the steering wheel is being turned.

Stellite An alloy of nickel, chromium, and tungsten, Stellite® is nonmagnetic. Some valves use this product only on the tip of the valve to help reduce wear in places where the rocker arm contacts the valve stem on engines that do not use a roller rocker arm.

Stepper motor A motor that moves a specified amount of rotation.

Stochiometric ratio Engines consume about 15 times more air than gasoline, this ratio of air to fuel is called the stochiometric ratio. This ratio, which is 14.7:1 for gasoline, is the ratio where all the fuel is consumed in the combustion process and all the available oxygen is used.

Stock Order A stock order is used to order more parts from the supplier on a routine basis.

Stocking fee If a customer returns a part, a stocking fee may be charged based on the original purchase price.

Stoichiometric An air-fuel ratio of exactly 14.7:1. At this specific rate, all the gasoline is fully oxidized by all the available oxygen.

Stone wheel A grinding stone attached to a grinder used for cleaning, sharpening, or other similar operations.

Stop ring In synchronized construction there are a number of design variations, all are similar and include a hub, a sliding sleeve, a blocker ring, (or stop ring or synchronizer ring), keys, and springs.

Storage mode New tire-pressure warning sensors (transmitters) are shipped in storage mode. This mode prevents the battery from becoming discharged while in storage.

Straddle-mounted pinion The final drive pinion uses two opposed taper roller bearings to support a straddle-mounted pinion, but the distance between them is smaller than in the overhung design. Most noticeably, a third smaller bearing attaches to a stemlike machined pilot protruding from the gear-end of the drive pinion shaft.

Straight cut aviation snips A tin snip that is designed with curved jaws that allow a straight cut through sheet metal.

Straight time The amount of time actually spent performing a service operation.

Straightedge A straightedge is a precision-ground metal measuring gauge that is used to check the flatness of engine components when used with a feeler gauge.

Strategy-based diagnosis When diagnosing a heating and air air-conditioning system problem, most vehicle manufacturers recommend that the following steps be performed. By following the same steps each time an air air-conditioning issues is found is called strategy-based diagnosis.

Stratified mode Stratified catalyst heating mode. In this mode, there are two injections: The first injection is on the compression stroke just before combustion and the second injection is after combustion occurs to heat the exhaust. This mode is used to quickly warm the catalytic converter and to burn the sulfur from the NOx catalyst.

Stratosphere The earth's upper atmosphere. Most of the earth's ozone is located in the stratosphere.

Stress riser A nick or rust area in a spring that could cause the spring to break.

Stroke The stroke of an engine is the distance the piston travels from top dead center (TDC) to bottom dead center (BDC).

Strong hybrid Another term for "full hybrid." See *Full hybrid*.

Strut rod Suspension member used to control forward/backward support to the control arms. Also called *tension* or *compression rod* (TC rod) or *drag rod.*

Strut suspension A type of suspension system that uses struts.

Struts A structural part of a suspension that includes the shock absorber.

Stub shaft A short shaft which is part of the steering gear and attaches to the steering shaft assembly.

Stub-type frame A type of vehicle frame that only supports the front suspension and engine.

Stud removal tool A hand tool used with a breaker bar or ratchet to remove what is left of a broken stud.

Stud remover A stud removal tool grips the part of the stub above the surface and uses a cam or wedge to grip the stud as it is being rotated by a ratchet or breaker bar.

Stud A short rod with threads on both ends.

Subscription-Based Electronic Information Retrieval Systems A digital online parts catalog that allows Parts Specialists to quickly retrieve OEM and aftermarket parts information.

Suction line The line that connects the evaporator outlet to the compressor suction port.

Suction stroke The line that connects the evaporator outlet to the compressor suction port.

Sump The term sump is used to describe a location where oil is stored or held.

Sun gear The center member of a planetary gearset. The other members (planet carrier and ring) rotate around the sun gear, thus the term "planetary."

Sun load sensor A sensor that detects the amount of sunlight and radiant heat entering the vehicle.

Sun roof A sun roof is basically any kind of panel on the roof of a car that permits light, air, or both to come into a vehicle, but only if the panel is opened.

Sun shades Sun shades are fabric or screen-like material installed on the inside of the vehicle that can be raised, lowered, or moved to block the rays of the sun from entering the interior of the vehicle.

Supercharger A supercharger is an engine-driven air pump that supplies more than the normal amount of air into the intake manifold, and boosts engine torque and power. A supercharger provides an instantaneous increase in power without any delay.

Superheat The heat that warms the refrigerant is referred to as superheat. Superheat is usually measured as the actual temperature difference between the boiling point of the refrigerant at the inlet and at the outlet of the evaporator.

Supersession Bulletin A Supersession Bulletin alerts the parts specialist of a superseded part.

Supplemental brake assist (SBA) Supplemental brake assist (SBA) is a motor-driven vacuum pump that can supplement engine vacuum to the vacuum brake booster.

Suppression diode A diode installed in the reverse bias direction and used to reduce the voltage spike that is created when a circuit that contains a coil is opened and the coil discharges.

Surface finish All crankshaft journals are ground to a very smooth finish. Surface finish is measured in micro inches; and the smaller the number, the smoother the surface.

Surface-to-volume ratio This ratio is an important design consideration for combustion chambers. A typical surface to-volume ratio is 7.5:1, which means the surface area of the combustion chamber divided by the volume is 7.5.

Surge tank A reservoir mounted at the highest point in the cooling system.

SVO Vegetable oil is a triglyceride with a glycerin component joining three hydrocarbon chains of 16 to 18 carbon atoms each, called straight vegetable oil (SVO). Other terms used when describing vegetable oil include: 1. Pure plant oil (PPO)—a term most often used in Europe to describe SVO. 2. Waste vegetable oil (WVO)—this oil could include animal or fish oils from cooking. 3. Used cooking oil (UCO)—a term used when the oil may or may not be pure vegetable oil

SVR Sealed Valve Regulated. A term used to describe a type of battery that is valve regulated lead acid or sealed lead acid.

SWCAN An abbreviation for single wire CAN (Controller Area Network).

Swept area The amount of brake drum or rotor friction surface that moves past the brake linings every time the drum or rotor completes a rotation.

Switching The turning on and off of the primary circuit is called switching.

Symmetrical If the lift is the same, the cam is called symmetrical.

Synchromesh transmission fluid (STF) Manual transmission fluid (sometimes called synchromesh transmission fluid, or STF) can be defined as an ATF-like fluid that contains special friction modifiers that are intended for specific manual transmissions.

Synchronizer assemblies The real "shifting" in a synchromesh transmission takes place in the synchronizer assemblies, not the gears. Most synchronizer assemblies ride on the output shaft between two gears. A synchronizer assembly is named for the gears on either side of it, which are the two speeds that it engages.

Synchronizer keys Small, spring-loaded detent keys, also called synchronizer keys or struts, ride in slots on the outer sleeve. The stop ring has slots to match these keys. This allows the stop ring to rotate slightly, relative to the sleeve, before the keys hit the sides of their slots and stop the stop ring.

Synchronizer ring In synchronized construction there are a number of design variations, all are similar and include a hub, a sliding sleeve, a blocker ring, (or stop ring or synchronizer ring), keys, and springs.

Synthetic grease Lubrication of moving or sliding components prevents noise from being generated as the parts move over each other. Many vehicle manufacturers recommend Synthetic grease.

Synthetic retainers A type of retention method for holding together parts of a universal joint.

System main relays (SMRs) System Main Relays (SMRs) are heavy duty relays that control the high voltage circuit between the battery and the other components of the high voltage system. SMRs are often referred to as contactors. Depending on the design of the battery control system, the battery will contain one to three SMRs.

Tag number Sometimes the vehicle identification number (VIN) is needed to obtain the correct parts, but more often the transmission/transaxle identification number, also called the tag number.

Tail Pipe The tail pipe is the last pipe in the exhaust system and it carries the exhaust fumes out from under the vehicle and into the atmosphere.

Tandem Solenoid (TS) Starter has two solenoids allows the starter to engage the flywheel of the engine when it is still moving, such as when the vehicle is coasting to a stop. A tandem solenoid starter design is also able to start the engine within 0.5 and 1.5 seconds, compared to about 3 seconds for a conventional starter.

Tandem-diaphragm vacuum booster Dual-diaphragm or tandem-diaphragm vacuum boost are designed to increase the total area without increasing the physical diameter of the booster.

Tap test The simple tap test involves tapping (not pounding) on the catalytic converter using a rubber mallet. If the substrate inside the converter is broken, the converter rattles when hit. If the converter rattles, a replacement converter is required.

Tap A metal cutting tool used to create threads in metal after a hole of the proper size has been drilled.

Taper face ring A taper face ring contacts the cylinder wall at the lower edge of the piston ring.

Tapered roller bearings A type of antifriction bearing that uses tapered rollers between the inner and outer races.

Task manager On OBD-II systems, the powertrain control module (PCM) incorporates a special segment of software. On Ford and GM systems, this software is called the diagnostic executive. On Chrysler systems, it is called the task manager.

Teacher A role played by a mentor.

Team leader An experienced technician who helps advise a small group of technicians who are paid according to the total amount of work completed by all members of the team.

Technical service bulletin (TSB) When a problem has a correction, the vehicle manufacturer releases a technical service bulletin (TSB), which details the repair.

Technician (tech) An Automotive Technician is educated and trained to inspect vehicles, remove and install vehicle components, repair vehicles, and has advanced understanding and knowledge the various vehicle operations.

Telematics Telematics is an interconnected system that combines telecommunications (cellular systems) and GPS navigation satellite system technology. Telematics is a method of monitoring a vehicle by combining a GPS system with on-board diagnostic systems.

Telescoping steering column A steering column that can be adjusted toward and away from the driver.

Telltale light The ESC lamp, called a telltale light, is required to remain on for as long as the malfunction exists, whenever the ignition is in "On" ("Run") position. The ESC malfunction telltale will flash to indicate when the ESC system is operating to help restore vehicle stability.

Temperature Temperature is the measure of the level of energy. Temperature is measured in degrees.

Temperature-blend door A door in the A/C and heat system that mixes cold and hot air to get the desired temperature.

Tensile strength The maximum stress used under tension (lengthwise force) without causing failure.

Terminal The metal end of a wire which fits into a plastic connector and is the electrical connection part of a junction.

Terminating resistors Resistors placed at the end of a high-speed serial data circuit to help reduce electromagnetic interference.

Test identification (TID) The global (generic) data is used by most state emission programs. Global OBD-II displays often use hexadecimal numbers. Hexadecimal coding is also used to identify tests (test identification [TID] and component identification [CID]).

Test light A light used to test for voltage. Contains a light bulb with a ground wire at one end and a pointed tip at the other end.

Thermactor pump The SAI pump, also called an AIR pump, a smog pump, or thermactor pump, is mounted at the front of the engine and can be driven by a belt from the crankshaft pulley.

Thermistor A resistor that changes resistance with temperature. A positive-coefficient thermistor has increased resistance with an increase in temperature. A negative-coefficient thermistor has increased resistance with a decrease in temperature.

Thermocouple Two dissimilar metal when connected and heated creates a voltage. Used for measuring temperature.

Thermoelectricity The production of current flow created by heating the connection of two dissimilar metals.

Thermostat A device that controls the flow in a system such as the engine cooling system based on temperature.

Thermostatic spring A second type of thermal fan has a thermostatic spring added to the silicone coupling fan drive.

Thickness gauge A feeler gauge (also known as a thickness gauge) is an accurately manufactured strip of metal that is used to determine the gap or clearance between two components.

Thickness variation (TV) Lack of parallelism, also called thickness variation (TV), is a variation in the thickness of the rotor when it is measured at several places around its circumference.

Thimble design A typical zirconia oxygen sensor has the sensing element in the shape of a thimble; therefore, it is often referred to as one of the following: 1. Thimble design 2. Cup design and Finger design.

Thimble The part of a micrometer that is rotated to move the spindle.

Thin-film-transistor (TFT) Thin-film-transistor (TFT) liquid-crystal display (LCD) is a type of a liquid-crystal display that uses thin-film-transistor (TFT) technology This type of display has enhanced image qualities and contrast compared to simple light-driven LCDs.

Third gear In third gear, the shift linkage centers the 1–2 synchronizer sleeve and moves the 3–4 synchronizer sleeve back toward the third speed gear. The synchronizer assembly locks the third speed gear to the output shaft.

Third-class lever A type of lever where the fulcrum is located at the end of the lever and the force is applied to the middle of the lever.

Threaded insert A type of thread repair where the original threads are replaced by an insert that contains the same size threads as the original on the inside of the insert.

Three cs (concern, cause, correction) After the service work has been performed, the service technician should then fill out the work order and describe what work was performed. These are called the “three Cs.” Concern—Write on the work order what was done to confirm the customer’s concern. Cause—The service technician should write the cause of the problem. Correction—The service technician should write what was done to correct the problem.

Three-angle valve job A three-angle valve job means that the valve seats are ground three times.

(Three) 3-minute charge test A method used to test batteries. Not valid for all types of batteries.

Three-position actuator A three-position actuator is able to provide three air door positions, such as the bi-level door, which could allow defrost only, floor only, or a mixture of the two.

Three-way converter (TWC) In a three-way (catalytic) converter (TWC) all three exhaust emissions (NOx, HC, and CO) are converted to carbon dioxide (CO2) and water (H2O).

Threshold voltage Another name for barrier voltage or the voltage difference needed to forward bias a diode.

Throating angle A 60-degree stone or cutter to remove material right below the valve seat to increase flow in or out of the combustion chamber. This angle is called the throating angle.

Throttle position (TP) sensor Signals the computer as to the position of the throttle.

Throttle-body temperature (TBT) Some engines use a throttle-body temperature (TBT) sensor to sense the temperature of the air entering the engine, instead of an intake air temperature sensor.

Through bolts The bolts used to hold the parts of a starter motor together. The long bolts go though field housing and into the drive-end housing.

Throws The term used to describe the number of output circuits there are in a switch.

Thrust bearing A thrust bearing supports these loads and maintains the front-to-rear position of the crankshaft in the block.

Thrust line The direction the rear wheels are pointed as determined by the rear wheel toe.

Thrust plate Each camshaft must have some means to control the shaft end thrust. One method is to use a thrust plate between the camshaft drive gear or sprocket and a flange on the camshaft.

Tie rods A parallelogram-type linkage uses four tie rods, two inner and two outer (left and right).

Tilt steering column A type of steering column that can be moved upward or downward to fit the driver.

Time base The time defined per each horizontal division on the display.

Time-of-use (TOU) A time-of-use (TOU) electric rate plan is needed to achieve the largest savings for charging. A TOU plan offers lower electric rates during off-peak periods (usually 11 PM until 5 AM), with higher rates for using electricity during high-demand times. Because most EVs are parked at home overnight, TOU rates are a wise choice for most EV owners.

Tin snips A hand tool used to cut sheet metal, thin cardboard, or similar material.

Tinnerman nuts Used to keep the brake drums on at the assembly plant. Can be removed and discarded when servicing the drum brake for the first time.

Tire rotation A term used to describe moving wheel/tire assemblies from one position on a vehicle to another.

Tire slip The difference between the actual speed and the rate at which the tire tread moves across the road surface.

Tire-pressure monitoring system (TPMS) A tire-pressure monitoring system (TPMS) is a system that detects a tire that has low inflation pressure and warns the driver.

Toe The inward or outward angle of the front or rear wheels as viewed from overhead.

Tolerance adjustment An alignment method that involves loosening all suspension mounting fasteners and retightening.

Tone generator tester A type of tester used to find a shorted circuit that uses a tone generator. Headphones are used along with a probe to locate where the tone stops which indicates were in the circuit the fault is located.

TOOT Turning radius is also called toe-out on turns, abbreviated TOT or TOOT, and is determined by the angle of the steering knuckle arms.

Top dead center (TDC) The highest point in the cylinder that the piston can travel. The measurement from bottom dead center (BDC) to TDC determines the stroke length of the crankshaft.

Topping angle A part of the three-angle valve job that is the third angle and uses a 30-degree stone or cutter to smooth the transition between the valve seat and the cylinder head, again to increase flow in or out of the combustion chamber. This angle is called the topping angle.

Torque angle To have a more constant clamping load from bolt to bolt.

Torque arm An arm that attaches the rear differential assembly to the body of the vehicle.

Torque converter clutch (TCC) Lockup torque converters reduce slippage by using a torque converter clutch (TCC) to lock the impeller to the cover (shell).

Torque steer Torque steer occurs in front-wheel-drive vehicles when engine torque causes a front wheel to change its angle (toe) from straight ahead. The resulting pulling effect of the vehicle is most noticeable during rapid acceleration, especially whenever upshifting of the transmission creates a sudden change in torque.

Torque wrench A wrench that registers the amount of applied torque.

Torque A twisting force measured in pounds-feet (lb.-ft) or Newton-meters (N-m) which may result in motion.

Torque-to-yield (TTY) Many engines use a tightening procedure called the torque-to-yield (TTY) method. The purpose of the TTY procedure is to have a more constant clamping load from bolt to bolt.

Torsion bar A type of spring in the shape of a straight bar. One end is attached to the frame of the vehicle, and the opposite end is attached to a control arm of the suspension. When the wheels hit a bump, the bar twists and then untwists.

Torsional dampers Around the center hub of the clutch disc are torsional dampers that absorb the initial shock of engagement and help dampen engine-firing in pulses being transmitted into and through the transmission/transaxle.

Total circuit resistance The total resistance in a circuit.

Total Environmental Warming Impact (TEWI) The Total Environmental Warming Impact (TEWI) index rates the impact of various refrigerants along with the energy required to per-form the cooling operation.

Total indicator runout (TIR) In grinding a valve seat, the maximum acceptable variation is 0.002 inch and called the total indicator runout (TIR) of the valve seat.

Total toe The total (combined) toe of both wheels, either front or rear.

Touch screen A type of drive information screen that uses capacitive circuits to detect the presence of a finger pointing to an icon or symbol on the screen.

TPC Tire Performance Criteria.

Track rod A horizontal steel rod or bar attached to rear axle housing at one end and the frame at the other to keep the center of the rear axle centered on the body. Also known as a *panhard rod.*

Traction control (TC) The electromechanical parts used to control wheel slip during acceleration.

Trade number The number stamped on an automotive light bulb. All bulbs of the same trade number have the same candlepower and wattage, regardless of the manufacturer of the bulb.

Trailing arm A rear suspension arm that attaches to the frame or body in front of the rear axle.

Trailing shoe The rear facing drum brake shoe on a leading/trailing type of drum brake.

Trainee a person undergoing training for a particular job or profession.

Tramp An up and down vibration of a tire/wheel assembly usually due to out-of-round tire or out-of-balance condition.

Transaxle A front-wheel-drive vehicle uses a transaxle, which is a combination of a transmission and differential in one assembly. Drive axle shafts then transfer the engine torque to the front drive wheels from the output of the transaxle.

Transceiver A transceiver is inside the vehicle and receives the signal transmitted by the transponder in the key. A “transceiver” functions as both a reviewer and a transmitter.

Transducers An electrical device that changes a varying pressure into a variable voltage.

Transfer cable A transfer cable transmits force to an intermediate lever or equalizer to the application cables.

Transfer case There are many types of methods of powering all four wheels. Many include a transfer case to split engine torque to both the front and the rear wheels.

Transistor A semiconductor device that can operate as an amplifier or an electrical switch.

Transmission band A transmission band stops and holds one planetary gear set member so that another member can react against the held member and develop output motion.

Transmission case The center housing is usually referred to as the transmission case.

Transmission fluid temperature The transmission fluid temperature (TFT), also called transmission oil temperature (TOT), sensor is an important sensor for the proper operation of the automatic transmission.

Transmission range sensor (TRS) A multi-contact switch operated by the manual shift lever.

Transmission temperature sensor (TTS) A Negative Temperature Coefficient (NTC) thermistor used to measure temperature of the transaxle.

Transmitter ID A replacement TPMS transmitter has an 8-digit number, called the transmitter ID, on each valve/transmitter assembly.

Transponder The transponder is mounted in the key or the body of the key fob. A transponder has an antenna, which consists of a coil of wire, as well as a circuit board containing the processing electronics and data memory.

TREAD Act The Transportation Recall Enhancement, Accountability, and Documentation (TREAD) Act requires that all vehicles be equipped with a tire-pressure monitoring system that will warn the driver in the event of an underinflated tire.

Tread The rubber part of a tire that touches the road.

Trigger level The voltage level that a waveform must reach to start display.

Trigger slope The voltage direction that a waveform must have to start display. A positive slope requires the voltage to be increasing as it crosses the trigger level; a negative slope requires the voltage to be decreasing.

Trouble light A light used to help a service technician see while performing service work on a vehicle.

Troxler effect The Troxler effect is a visual effect where an image remains on the retina of the eye for a short time after the image has been removed. The effect was discovered in 1804 by Igney Paul Vital Troxler (1780 1866), a Swiss physician. Because of the Troxler effect, headlight glare can remain on the retina of the eye and create a blind spot.

Trunnions The four arms of a typical universal joint.

Trust The belief in another person’s reliability, ability, or confidence that the person will do and/or act based on their statements. All this conversation should be based on trust and the relationship you have built with the customer during his or her experience with you and the shop.

Tube-nut wrench Line wrenches are also called flare-nut wrenches, fitting wrenches, or tube-nut wrenches and are designed to grip almost all the way around a nut used to retain a fuel or refrigerant line, and yet be able to be installed over the line.

Tuftriding To improve wear resistance, some manufacturers harden the crankshaft journals. Methods used to harden the crankshaft journals includes Tuftriding, another variation of this process, involves heating the crankshaft in a molten cyanide salt bath. Tuftriding is a trade name of General Motors.

Turbine pump A turbine pump is the most common because it tends to be less noisy. Sometimes called turbine, peripheral, and side-channel, these units use an impeller that accelerates the fuel particles before actually discharging them into a tract where they generate pressure via pulse exchange.

Turbine The turbine is located on the engine side of the converter. The impeller vanes pick up fluid in the converter housing and direct it toward the turbine.

Turbo lag The delay between acceleration and turbo boost is called turbo lag

Turbocharger An exhaust-powered supercharger.

Turning torque The drive pinion nut is then tightened farther until the turning torque is within specifications.

Turns ratio The ratio between the number of turns used in the primary winding of the coil to the number of turns used in the secondary winding. In a typical ignition coil the ratio is 100:1.

Twin clutch transmission Another term used to describe a dual-clutch automatic transmission/transaxle.

Twin I-beam A twin I-beam front suspension was used for over 30 years on Ford pickup trucks and vans, beginning in the mid1960s. Strong steel twin beams that cross provide independent front suspension operation with the strength of a solid front axle.

Twist Form into a bent, curling, or distorted shape. The head should be checked in five planes. Checking the cylinder head gasket surface with a precision straightedge in five planes checks the head for warpage, distortion, bend, and twist.

Twisted pair A pair of wires that are twisted together from 9 to 16 turns per foot of length. Most are twisted once every inch (12 per foot) to help reduce electromagnetic interference from being induced in the wires as one wire would tend to cancel out any interference pickup up by the other wire.

UART-based protocol (UBP) Newer Fords use the CAN for scan tool diagnosis, but still retain SCP and UART-based protocol (UBP) for some modules.

UCO Vegetable oil is a triglyceride with a glycerin component joining three hydrocarbon chains of 16 to 18 carbon atoms each, called straight vegetable oil (SVO). Other terms used when describing vegetable oil include: 1. Pure plant oil (PPO)—a term most often used in Europe to describe SVO. 2. Waste vegetable oil (WVO)—this oil could include animal or fish oils from cooking. 3. Used cooking oil (UCO)—a term used when the oil may or may not be pure vegetable oil

U-joints Universal joints.

ULSD Ultra-Low-Sulfur Diesel. Diesel fuel with a maximum sulfur content of 15 parts per million.

Ultracapacitor Ultracapacitor cells are based on double-layer technology, in which two activated carbon electrodes are immersed in an organic electrolyte. The electrodes have a very large surface area and are separated by a membrane that allows ions to migrate, but prevents the electrodes from touching.

Ultrasonic cleaning Ultrasonic cleaning is used to clean small parts that must be absolutely clean, such as hydraulic lifters and diesel injectors.

Ultrasonic object sensors Ultrasonic object sensors built into the fender and front and rear bumper assembly. The ultrasonic proximity detectors are used to measure the distances to nearby objects. The sensors send out acoustic pulses and a control unit measures the return interval of each reflected signal, calculating object distances.

Ultraviolet (UV) radiation Ultraviolet (UV) radiation is divided into three. The designations include:

- Designation "A," abbreviated UVA, is not absorbed by the ozone layer and generally is not damaging to bio-logical organisms.
- Designation "B," abbreviated UVB, is only partially absorbed by the ozone layer and can cause damage to biological organisms.
- Designation "C," abbreviated UVC, is almost completely absorbed by the ozone layer and represents little, if any, health concerns.

UNC (Unified national Coarse) A type of thread used on fasteners.

Underground storage tank (UST) An underground storage tank system (UST) is a tank and any underground piping connected to the tank. Used oil must be stored in compliance with an existing underground storage tank (UST)

Understeering Understeering is when the front of the vehicle tends to continue straight ahead when turning, a condition that is also called plowing or tight. If this condition is detected during a right turn, the ESC system would apply the right rear wheel brake to bring the vehicle back under control.

UNF (Unified national Fine) Unified national fine.

Unibody Unit-body construction (sometimes called unibody) is a design that combines the body with the structure of the frame. The body is composed of many individual stamped-steel panels welded together. The strength of this type of construction lies in the shape of the assembly.

Unit-body Unit-body construction (sometimes called unibody) is a design that combines the body with the structure of the frame. The body is composed of many individual stamped-steel panels welded together. The strength of this type of construction lies in the shape of the assembly.

Universal joint A joint in a steering or drive shaft that allows torque to be transmitted at an angle.

Upselling Upselling refers to the attempt to increase sales up and beyond what the customer first wanted.

Urea A chemical used to reduce oxides of nitrogen emission on diesel engines that use an SCR emission control system.

Used oil Any petroleum-based or synthetic oil that has been used.

Utility knife A handheld knife that uses replaceable blades.

UTQGS Uniform Tire Quality Grading System.

Vacuum bleeding Using a vacuum source to draw air from a brake hydraulic system.

Vacuum servo A vacuum controlled parking brake release mechanism controlled by an electrical solenoid.

Vacuum test Vacuum is pressure below atmospheric pressure and is measured in inches (or millimeters) of mercury (Hg).

Vacuum Any pressure less than atmospheric pressure (14.7 psi).

Valence ring The outer most ring or orbit of electrons around a nucleus of an atom.

Valve (camshaft) overlap Is the number of degrees of crankshaft rotation during which both intake and exhaust valves are open.

Valve body A valve body is where most of the valves in a transmission are located, and is attached to the case with bolts. Valve bodies can be either cast aluminum or cast iron.

Valve duration Valve duration is the number of degrees by which the crankshaft rotates when the valve is off the valve seat.

Valve face The location on a valve where the valve rests on the valve seat of the cylinder head.

Valve float The job of the hydraulic lifter is to take up all clearance in the valve train. Occasionally, engines are run at excessive speeds. This tends to throw the valve open, causing valve float. During valve float, clearance exists in the valve train. The hydraulic lifter takes up this clearance as it is designed to do.

Valve guides The valve guide supports the valve stem so that the valve face will remain perfectly centered, or concentric, with the valve seat

Valve lash Valve train clearance is also called valve lash, which is needed to help compensate for thermal expansion and wear. Valve train clearance must not be excessive, or it causes noise or results in premature failure.

Valve seat inserts The valve guide supports the valve stem so that the valve face will remain perfectly centered, or concentric, with the valve seat. Removable or pressed-in valve guides and valve seat inserts are always used in aluminum heads.

Valve seat The place in the cylinder head where the valve rests when closed.

Valve spring inserts (VSI) Also called shims and are used to adjust the installed height of valve springs.

Valve spring surge The tendency of a valve spring to vibrate.

Valve spring Holds the valve against the seat.

Valve stem height Valve stem height is the distance the valve stem is above the spring seat. Valve stem height is a different measurement from installed height.

Vane compressor Vane compressor has vanes that contact the rotor housing at each end, and they slide to make a seal at each end as the rotor turns.

Vane phaser A vane phaser is an actuator used in most variable valve timing systems and uses a rotor with four vanes, which is connected to the end of the camshaft. The rotor is located inside the stator, which is bolted to the cam sprocket. The stator and rotor are not connected. Oil pressure is controlled on both sides of the vanes of the rotor, which creates a hydraulic link between the two parts. The oil control valve varies the balance of pressure on either side of the vanes and thereby controls the position of the camshaft. A return spring is used under the reluctor of the phaser to help return it to the home or zero degrees position.

Vapor lock At higher temperatures, liquid gasoline can easily vaporize, which can cause vapor lock. Vapor lock is a lean condition caused by vaporized fuel in the fuel system.

Variable force solenoids (VFS) Variable force solenoids (VFS) is a type of electronic pressure regulation.

Variable fuel sensor General Motors, Ford, Chrysler, Mazda, and Honda are a few of the manufacturers offering E85-compatible vehicles. E85- vehicles use fuel system parts designed to withstand the additional alcohol content, modified driveability programs that adjust fuel delivery and timing to compensate for the various percentages of ethanol fuel, and a fuel compensation sensor that measures both the percentage of ethanol blend and the temperature of the fuel. This sensor is also called a variable fuel sensor.

Variable rate springs A type of valve spring that provides a variable force depending on how much it is compressed.

Variable ratio A steering gear design that provides a variable steering gear ratio.

Variable valve timing (VVT) On newer engines, the camshaft can have the capability of a variable valve-timing feature that changes the camshaft specifications during different operating modes.

Variable valve timing and lift electronic control (VTEC) A valve train control system developed by Honda Motor Company to enhance engine output and efficiency over a wide RPM range.

Variable A variable is a measurement of something that changes, such as engine speed or time.

Variable-delay wipers Windshield wipers whose speed can be varied.

Variable-position actuator A variable-position actuator is capable of positioning a valve in any position.

Variators Two variable width pulleys to change the gear ratio in a continuously variable transmission.

Vehicle emissions control information (VECI) This sticker is located under the hood on all vehicles and includes emission-related information that is important to the service technician.

Vehicle identification number (VIN) Alphanumeric number identifying vehicle type, assembly plant, powertrain, etc.

Vehicle safety certification label A vehicle safety certification label is attached to the left side pillar post on the rearward-facing section of the left front door. This label shows the month and year of manufacture, the VIN, as well as the gross vehicle weight rating (GVWR), which is the maximum weight of a vehicle as specified by the OEM.

Vehicle speed (VS) sensor The vehicle speed (VS) sensor is used by the electronic brake control module (EBCM) to help control the suspension system

Vehicle stability enhancement system (VSES) A General Motors term used to describe one type of electronic stability control system.

Vent port The Society of Automotive Engineers (SAE) term for the front port of a master cylinder, also called the compensating port or bypass.

Vent valve Blow-off valve (BOV). Also called a dump valve or vent valve, the BOV features an adjustable spring design that keeps the valve closed until a sudden release of the throttle. The resulting pressure increase opens the valve and vents the pressurized air directly into the atmosphere.

V-FFV Virtual Flexible Fuel Vehicle. This fuel system design does not use a fuel compensation sensor and instead uses the vehicle's oxygen sensor to adjust for different fuel compositions.

Vibration damper A device designed to compensate for and reduce the effects of torsional vibration in the crankshaft of an engine. A vibration damper is also called a harmonic balancer.

Vibration order A description used to help define a vibration.

Virtual display A virtual display is a dash that allows the driver to select what data is being displayed. Many vehicles are equipped with an LCD dash display that can be changed to display various functions based on the driver's preference. This allows the dash display to be totally customized to what the driver wishes to see displayed.

Viscosity Resistance to flow of an oil. A high-viscosity oil is thicker than a low-viscosity oil.

Viscosity index (VI) An index of the change in viscosity between the cold and hot extremes.

Viscous coupling A type of device used to allow a limited difference in speed of two axles.

Vise-Grip A brand name for locking pliers.

Visual inspection A visual inspection of the under-hood items includes items that are part of the heating and air conditioning system.

Voice activation Most recent vehicles include voice commands, commonly called voice activation, that can be used to perform various functions or settings in the vehicle.

Voice inflection Voice inflection is a variation in the pitch, timing, or loudness of the voice. Pitch is made up of the highs and lows of your voice.

Voice recognition A system which uses a microphone and a speaker connected to an electronic module which can control the operation of electronic devices in a vehicle.

Volatile organic compounds (VOC) Volatile organic com-pounds (VOC) are gases emitted by paints, solvents, aerosol sprays, cleaners, glues, permanent markers, pesticides, and fuels.

Volatility A measurement of the tendency of a liquid to change to vapor. Volatility is measured using RVP, or Reid Vapor Pressure.

Voltage drop Voltage loss across a wire, connector, or any other conductor. Voltage drop equals resistance in ohms times current in amperes (Ohm's law).

Voltmeter An electrical test instrument used to measure volts (unit of electrical pressure). A voltmeter is connected in parallel with the unit or circuit being tested.

Volt Unit of electrical pressure.

Volumetric efficiency The ratio between the amount of air-fuel mixture that actually enters the cylinder and the amount that could enter under ideal conditions expressed in percent.

Vortex flow Vortex flow is the flow of the fluid from the impeller to the turbine and back to the impeller.

VRLA Valve-regulated lead–acid battery. A sealed battery that is both spill proof and leakproof. AGM and gelled electrolyte are both examples of VRLA batteries.

Wander A type of handling which requires constant steering wheel correction to keep the vehicle going straight.

Wankel engine The rotary engine is also a Wankel engine named after its inventor, Felix Heinrich Wankel (1902–1988), a German inventor.

Warehouse distributor A jobber or parts retailer usually gets parts from a large regional warehouse distributor. The warehouse distributor can either purchase parts directly from the manufacturer or from an even larger central warehouse.

Warpage Warpage is to bend out of shape. The head should be checked in five planes. Checking the cylinder head gasket surface with a precision straightedge in five planes checks the head for warpage, distortion, bend, and twist.

Warranties A guarantee that is issued to a customer by the manufacturer, promising to replace or repair a qualified item within a specified period of time.

Washcoat A substrate that is coated with a porous aluminum material called the washcoat, which makes the surface rough.

Washers Flat or shaped pieces of round metal with a hole in the center used between a nut and a part or casting.

Wastegate e. A wastegate is a valve similar to a door that can open and close. It is a bypass valve at the exhaust inlet to the turbine, which allows all of the exhaust into the turbine, or it can route part of the exhaust past the turbine to the exhaust system.

Waste-spark ignition Waste-spark ignition is another name for distributorless ignition system (DIS) or electronic ignition (EI). Waste-spark ignition was introduced in the mid-1980s and uses the onboard computer to fire the ignition coils.

Water (H2O) During combustion, the HC combines with the air to form water (H2O) and carbon dioxide (CO2), plus nitrogen (N2) and some other non-desirable gases.

Water fade A lack of braking caused by water getting between the friction material and the brake drum or rotor.

Water Jacket coolant is circulated by a water pump through passages in the cylinder block and head called water jackets.

Water pump pliers For gripping larger objects, a set of multigroove adjustable pliers is a commonly used tool of choice by many service technicians. Originally designed to remove the various size nuts holding rope seals used in water pumps, the name water pump pliers is also used.

Water pump A mechanical device responsible for circulating coolant through a liquid cooling system.

Water-fuel separator Between the fuel tank and the lift pump is a water-fuel separator. Water is heavier than diesel fuel and sinks to the bottom of the separator.

Watt's law The formula for Watts is the voltage times the amperes in the circuit that represents the electrical power in the circuit.

Watt An electrical unit of power; 1 watt equals current (amperes) x voltage (1/746 hp). Named after James Watt, a Scottish inventor.

Watts linkage An element used in the rear suspension of some vehicles to keep the rear axle centered under the body.

Ways Places where the disc brake caliper contacts on a sliding-type caliper design.

Wear bars *Wear indicators (wear bars) are strips of bald tread that show when the tread depth is down to 2/32 inch, which is the legal limit in many states.*

Weight bias The amount of weight on the front compared to the rear of a vehicle.

Weight The weight of an object is the force of gravity on the object and may be defined as the mass times the acceleration of gravity. Therefore, mass means the property of an object and weight is a force.

Weld pool An arc is struck between the end of a wire electrode and the workpiece, melting both to form a puddle of molten steel, called the weld pool.

Welsh plugs Core holes left in the external block wall are machined and sealed with soft core plugs or expansion plugs (also called freeze plugs or Welsh plugs).

Wet compression test If the compression test reading indicates low compression on one or more cylinders, add three squirts of oil to the cylinder and retest. This is called a wet compression test, when oil is used to help seal around the piston rings.

Wet cylinder sleeve Some engines have die-cast aluminum blocks with replaceable cast-iron cylinder sleeves. The sleeves are sealed at the block deck and at their base. Coolant flows around the cylinder sleeve, so this type of sleeve is called a wet cylinder sleeve.

Wet sump In most engines, oil is held in the oil pan and the oil pump draws the oil from the bottom. This type of system is called a wet sump oil system.

Wheel rate Similar to spring rate, but includes the ratio of wheel travel to spring travel to determine the force per inch rate.

Wheel speed sensors (WSS) The purpose and function of wheel speed sensors, abbreviated WSS, is to monitor the speed of the wheels.

WHMIS Workplace Hazardous Materials Information Systems.

Wide-band O2S Wide-band O2S sensors are used by most vehicle manufacturers to ensure that the exhaust emissions can meet the current standard. A wide-band oxygen sensor is capable of supplying air-fuel ratio information to the PCM. Compared with a conventional zirconia oxygen sensor, the wide-band oxygen sensor has the following features. 1. The ability to detect exhaust air-fuel ratio from as rich as 10:1 to as lean as 23:1 in some cases 2. Cold start activity within as little as 10 seconds

Windage tray Tray that is sometimes installed in engines to eliminate the oil churning problem.

Windshield wipers The assembly of motor, motor control, operating linkage plus the wiper arms and blades which are used to remove rain water from the windshield.

Wire brush wheel A wire brush wheel is often mounted on one end of a grinder and is used for cleaning parts and other similar operations.

Wiring schematic A drawing showing the wires and the components in a circuit using symbols to represent the components.

Witness mark Discoloration or scraping marks that show where two components have been touching or rubbing together.

Work hardened Bearing metals, like other metals, tend to fatigue and break after being flexed or bent a number of times. Flexing starts fatigue, which shows up as fine cracks in the bearing surface because the bearing material became work hardened.

Work light See Trouble Light.

Work order Contains all vehicle and customer information plus what service work is requested by the customer. Also called a *repair order*.

Work place charging (WPC) Work place charging (WPC) is very popular because the vehicle owner can charge their vehicle while at work and usually for free.

Work The transfer of energy from one physical system to another. Actually moving an object is work.

Worldwide harmonized Light vehicles Test Procedure (WLTP) In the United States the Environmental Protection Agency (EPA) estimates of electric vehicle range, while in Europe electric vehicle range uses the Worldwide harmonized Light vehicles Test Procedure (WLTP).

Worm gear A type of gear used in an older type of steering gear, which is attached to the steering shaft.

Worm holes Valve bodies have many fluid passages for the various transmission hydraulic circuits cast into them. These are sometimes called worm holes or worm tracks.

Worm tracks Valve bodies have many fluid passages for the various transmission hydraulic circuits cast into them. These are sometimes called worm holes or worm tracks.

WOW display A dash display when it first comes on and lights all possible segments. Can be used to test the dash display for missing lighted segments.

Wrench A hand tool used to grasp and rotate a threaded fastener.

Wrist pin The piston is attached to the connecting rod with a piston pin, also called a wrist pin. The piston pin is allowed to have a rocking movement because of a swivel joint at the piston end of the connecting rod.

Wrought alloys Aluminum and aluminum alloys that are mechanically shaped are called wrought alloys.

WVO Vegetable oil is a triglyceride with a glycerin component joining three hydrocarbon chains of 16 to 18 carbon atoms each, called straight vegetable oil (SVO). Other terms used when describing vegetable oil include: 1. Pure plant oil (PPO)—a term most often used in Europe to describe SVO. 2. Waste vegetable oil (WVO)—this oil could include animal or fish oils from cooking. 3. Used cooking oil (UCO)—a term used when the oil may or may not be pure vegetable oil

WWFC World Wide Fuel Charter. A fuel quality standard developed by vehicle and engine manufacturers in 2002.

Yaw rate sensor An input sensor usually located in the center of the vehicle that detects yaw as part of an electronic suspension system.

ZDDP The levels of phosphate and zinc found in engine oils are commonly referred to as zinc dialkyl dithiophosphate or (ZDDP or ZDP).

Zener diode A specially constructed (heavily doped) diode designed to operate with a reverse-bias current after a certain voltage has been reached. Named for Clarence Melvin Zener.

Zerk fitting A name for a chassis grease fitting, also known as an alemite fitting (named for Oscar U. Zerk).

Zero-emission vehicles (ZEVs) Electric vehicles that use battery power alone to propel the vehicle are called zero-emission vehicles (ZEVs).

Zirconia A zirconia oxygen sensor is made of zirconium dioxide (ZrO2), an electrically conductive material capable of generating a small voltage in the presence of oxygen.

ZrO2 A zirconia oxygen sensor is made of zirconium dioxide (ZrO2), an electrically conductive material capable of generating a small voltage in the presence of oxygen.

Zyglo To be seen, fluorescent penetrant requires a black light. It can be used on iron, steel, or aluminum parts. Cracks show up as bright lines when viewed with a black light. The method is commonly called Zyglo, a trademark of the Magnaflux Corporation.
